A "regular graph" is a graph in which all vertices have same degree k. We say then that the graph is "k-regular".

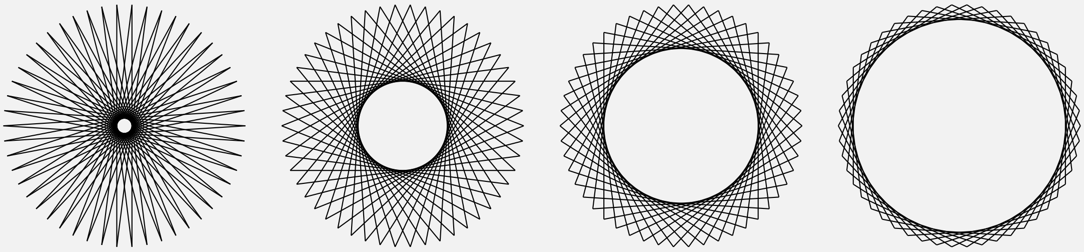

Figure 8.305: A few possible 2-regular graphs

D13. We say that a graph $G'=(X',E')$ is a "subgraph" of a graph $G=(X,E)$ when $X'\subseteq X$ and $E'\subseteq E$. We say that $G'=(X',E')$ is an "induced subgraph" of a graph $G=(X,E)$ provided $X'\subseteq X$ and E' contains all edges of E which are subsets of X'.

If G' is a subgraph of G and u and w are vertices of G', then by the definition of a subgraph, u and w are also vertices of G. However, if u and w are adjacent in G (i.e., there is an edge of G joining them), the definition of subgraph does not require that the edge joining them in G is also an edge of G'. If the subgraph g' has the property that whenever two of its vertices are joined by an edge in G, this edge is also in G', then we say that G' is an "induced subgraph".

Notice that every induced subgraph is also an ordinary subgraph, but not conversely. Think of a subgraph as the result of deleting some vertices and edges from the larger graph. For the subgraph to be an induced subgraph, we can still delete vertices, but now we only delete those edges that included the deleted vertices.

✍**Example:**

Consider the graphs:

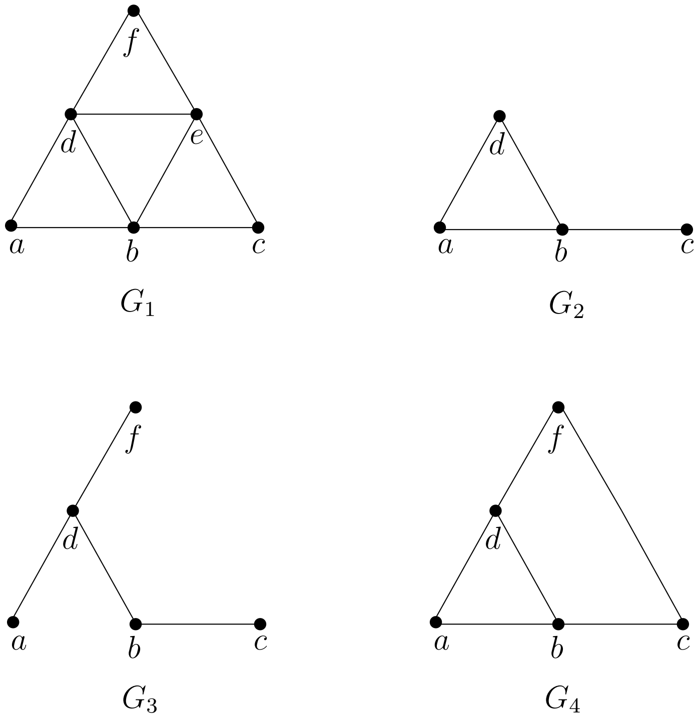

Figure 8.306: **Examples of subgraphs and induced graphs**

Here both $G_2(X_2, E_2)$ and $G_3(X_2, E_3)$ are subgraphs of $G_1(X_1, E_1)$. But only G_2 is an induced subgraph. Every edge in G_1 that connects vertices in G_2 is also an edge in G_2. In G_3, the edge $\{a, b\}$ is in E_1 but not E_3, even though vertices a and b are in X_3.

The graph $G_4(X_4, E_4)$ is not a subgraph of G_1, even though it looks like all we did is remove vertex e. The reason is that in E_4 we have the edge $\{c, f\}$ but this is not an element of E_1, so we don't have the required $E_4 \subseteq E_1$.

D14. A "covering subgraph" of a graph $G = (X, E)$ is a subgraph $G' = (X, E')$, that is to say a subgraph whose vertices are all vertices of G and whose edges are in E'.

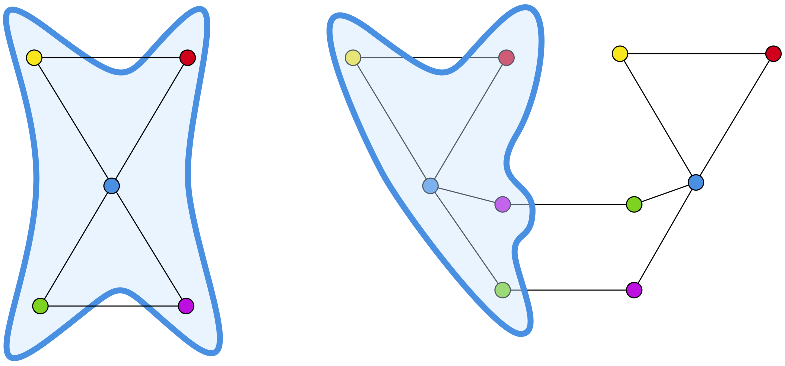

Figure 8.307: In the above figure, the graph on the right is a covering graph of the graph on the left

D15. For a graph of order n, there are two extreme cases for all its edges: either the graph has no edges or all possible edges connecting the vertices by pairs are present. In the latter case the graph is said named a "complete graph" or "strongly connex graph".

✍**Example:**

Here are some complete graphs for which we have well:

$$\frac{n(n-1)}{2} \tag{8.8.14}$$

edges. We notice that the first four graphs are planar (indeed you can see how it is possible, by projecting a vertices in the plane, to transform the fourth K_4 in K_4' in a way so that there are no more intersections). The fifth graph K_5 is non-planar (we can not find movements avoiding crossings):

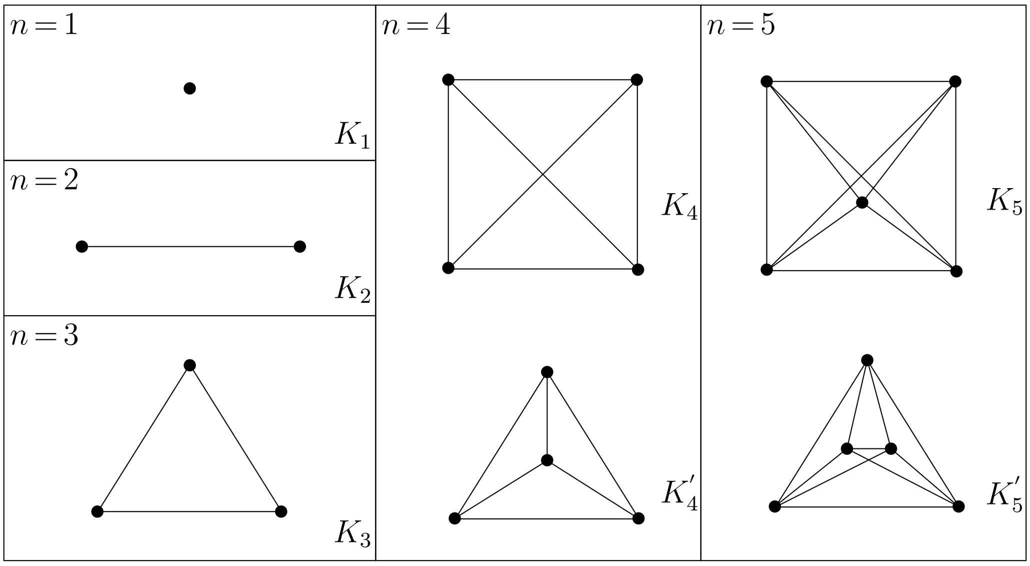

Figure 8.308: Example of complete graphs

A complete graph is therefore a graph where each vertex is connected to every other. The complete graph of order n is denoted by K_n. In this type of graph each vertex is of degree $n-1$.

A nice case to be processed is the "Star of David":

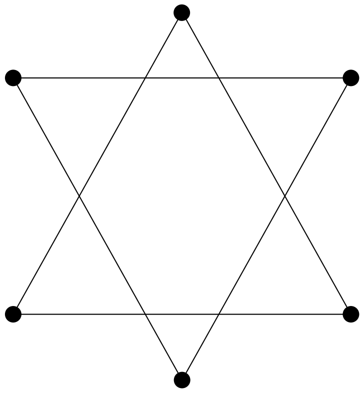

Figure 8.309: **Star of David**

which is obviously a complete graph by definition if and only if we join all vertices between them (and we lose the geometry of the star but we get a graph K_6):

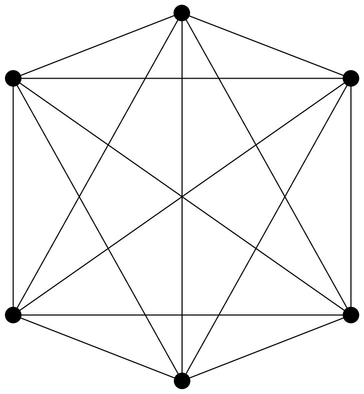

Figure 8.310: **Star of David completed**

Remark

This result is interesting in the field of management of the communication in business projects and IT security (see for the latter the section Cryptography at page 7216). For example, if you manage a project with 10 stakeholders (corresponding to n), so there are $n(n-1)/2$ possible communication channels (email or phone) possible, that is to says 45 (and in the field of IT security there would be 45 encryption symmetric keys system to generate). Hence the importance in project management to establish clear communication rules (in the form of a graph) if one does not want to be flooded by emails or phones unnecessarily (and in the field of security to implement asymmetric systems). We will also encounter this results in the liquid drop model of the nucleus in the Nuclear Physics section of the chapter Atomistic (see page 5141).

D16. A "stable graph" or "independent set" is subgraph without edges and a "clique" a complete subgraph.

In other words an independent vertex set of a graph G is a subset of the vertices such that no two vertices in the subset represent an edge of G.

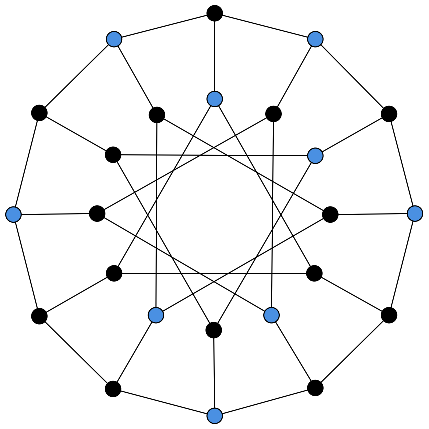

Figure 8.311: **Stable subgraph example (in blue)**

Remark

A "maximum independent" set is an independent set of largest possible size for a given graph G. The problem of finding such a set is a NP-hard optimization problem (see section Numerical Methods page 6291). As such, it is unlikely that there exists an efficient algorithm for finding a maximum independent set of a graph.

D17. In a graph, it is natural to want to move from summit to summit following the edges. Such a walk through n vertices is named a "string P_n" or "path":

A path is a list $P_k=(x_1,\ldots,x_k)$ of vertices such that there exists an edge in the graph between every pair of successive vertices: $\forall i=1\ldots k-1\;(x_i,x_{i+1})\in E$. The path length corresponds to the number of edges traversed: $k-1$.

A path is named "simple path" if each edge of the path is taken only once. Here for example a simple path with 5 vertices:

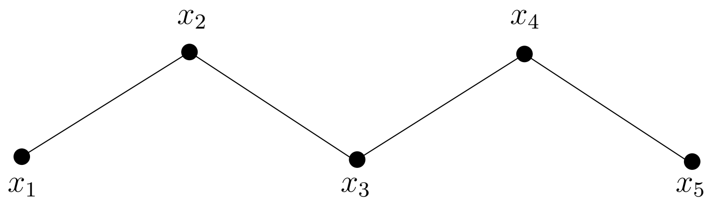

Figure 8.312: **Simple path example**

Thus, we also define a "cycle" as:

$$C_n=C_{k+1}=(x_1,\ldots,x_k,x_{k+1}) \tag{8.8.15}$$

as being a simple path ending at the starting point as $x_1=x_{k+1}$.

D18. A "simple cycle" is a cycle in which all the edges are different.

D19. A "directed graph" or "oriented graph" is a graph whose edges have a direction and re therefore named "arcs" (thus opposite to an undirected graph).

Remarks

R1. The terms "path" and "circuit" are normally reserved to directed graphs. For undirected graphs we use mainly the words "string" or "cycle". However, the formal definition is exactly the same in both cases, only changes the structure (directed graph or not) on which they are defined.

R2. An undirected graph is a symmetrical directed graph. Indeed, if an arc connects the vertice a to the vertice b top and another arc the vertice b to the vertice a, then it is of usage to trace only a simple line between a and b which we name ... an "edge".

D20. A path $P_k=(x_1,\ldots,x_k)$ is named "elementary path" if each of the vertices of the path is visited only once: $\forall i,j=1\ldots k \quad i\neq j, x_i\neq x_j$. An elementary path is therefore a simple path without cycle.

In a graph of order G we have the following properties:

P1. All elementary path is of length at most $n-1$. Indeed, an elementary path visiting at most 1 time each vertex of the graph, its length (number of edges) may actually not exceed $n-1$.

P2. The number of elementary paths in a graph is finite. Indeed, the number of paths of length $k(k=0,1,\ldots,n-1)$ is at most the combinatorial of a sequence of $k+1$ peaks distinguishable from n. There are therefore (see section Probabilities page 527):

$$A_n^p=\frac{n!}{(n-p)!} \tag{8.8.16}$$

possible paths.

The elementary paths are the natural restrictions we are looking at the concept of path. The question is whether we lose something by considering only the basic paths in a graph: can we always replace a path in a graph by an elementary path?

Lemma 8.29.1. The "König's lemma" answers this question affirmatively: from any path we can extract an elementary sub-path.

In other words: If there is a path between two vertices x and y, then there exists an elementary path between x and y.

Proof 8.29.2. The idea of the proof is to choose a particular path between x and y and show that it is elementary. Which path to choose? If a path has a circuit, this circuit is a detour on the road of x and y. A good candidate to be an elementary path appears to be a shortest path.

Among all the paths connecting x to y, let us choose a path:

$$P_k=(x_1=x,\ldots,x_k=y) \tag{8.8.17}$$

with the fewest possible edges. Suppose by contradiction that P_k is not elementary. There exists in this path a vertices z appearing at least two times along the path P_k.

Given i,j the first two indices such as $x_i=z$ and $x_j=z$:

$$P_k=(x_1=x,\ldots,x_i=z,\ldots,x_j=z,\ldots,x_k=y) \quad (8.8.18)$$

To get a contradiction, we just delete the cycle between $x_i=z$ and $x_j=z$. So we have a new path:

$$P'_k=(x_1=x,\ldots,x_{i_1},\ldots,x_{j+1},\ldots,x_k=y) \quad (8.8.19)$$

which is a path connecting x to y. Its length strictly less than P_k:

$$\text{Card}(P'_k)<\text{Card}(P'_k) \quad (8.8.20)$$

which contradicts our initial choice as a shortest path.

■ Q.E.D.

D21. A graph G is named "connected graph" or "connex graph" if and only if there is at least one simple path between each pair of vertices (the path being therefore not necessarily direct- can pass through one or more intermediate vertices).

Therefore, we have that a "connected component" $G'=(X',E')$ is a subgraph of G in which any two vertices are connected to each other by paths, and which is connected to no additional vertices in the supergraph.

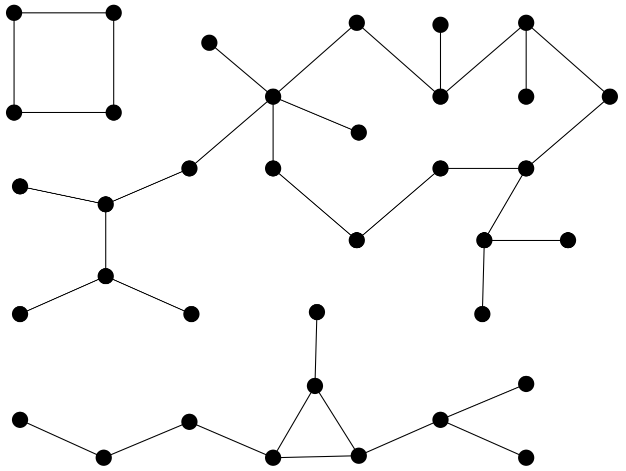

Figure 8.313: **Various connected graphs**

Remarks

R1. A graph with only one connected component is simply a... connected graph.

R2. An isolated node (of degree 0) always constitutes a connected component alone.

R3. The relation on the nodes "there is a path between ..." is an equivalence relation (reflexive, symmetric and transitive). The connected components of a graph correspond to equivalence classes of this relation.

We will suppose intuitive that a graph G of order n is always associated with at least $n-1$ edges.

D22. A "tree" or "spanning tree" is a connected graph (undirected) with no cycles (acyclic). In a tree the number of edges is equal to the number of vertices -1:

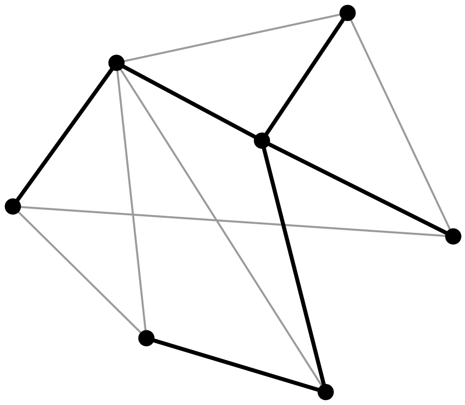

Figure 8.314: Example of a spanning tree

A minimum spanning tree with the minimum weight values of a valuated graph where all nodes are browsed is named a "minimum spanning tree":

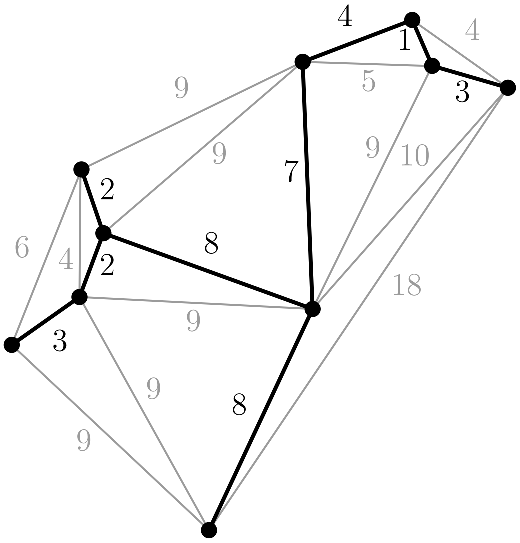

Figure 8.315: Example of a minimum spanning tree (source: Wikipedia)

If you imagine that every point is a city, and that a country has not enough money for now for the maintenance of all existing routes between several cities, the minimum spanning tree gives mathematically (without any other considerations) the road to clean and repair to minimize costs while connecting all the towns together.

D23. A "valuated tree" or "weighted graph" is a tree (respectively a graph) where the edges have positive values (weights). The sum of all the values that are on the browsed edges is then named the "cost tree Value" (respectively "cost graph value").

Remark

The valued trees are used in many fields. These include computer networks in which we seek to optimize the number of interconnections between machines to avoid duplication of items of data packets or project management (see example below).

✍**Example:**

An excellent practical example of a connected weighted and directed graph and directed (abbreviated to as "digraph") is the one used in project management to calculate the critical path (of a project without constraints). This is a graph representing the dependencies between n intermediate tasks required to complete a project, commonly named "Gantt chart" or even "scheduling graph". The length (weight) of each task is the value of the externally incident weights to the correspondent node arcs. Edges represent the sequences of tasks. We are always adding an initial and final node (in the world of project management people rather talking about "milestone"...). The first node is connected by a zero value arc to all nodes without predecessors, and all nodes without successors are connected to the final node. The resulting graph should obviously be acyclic.

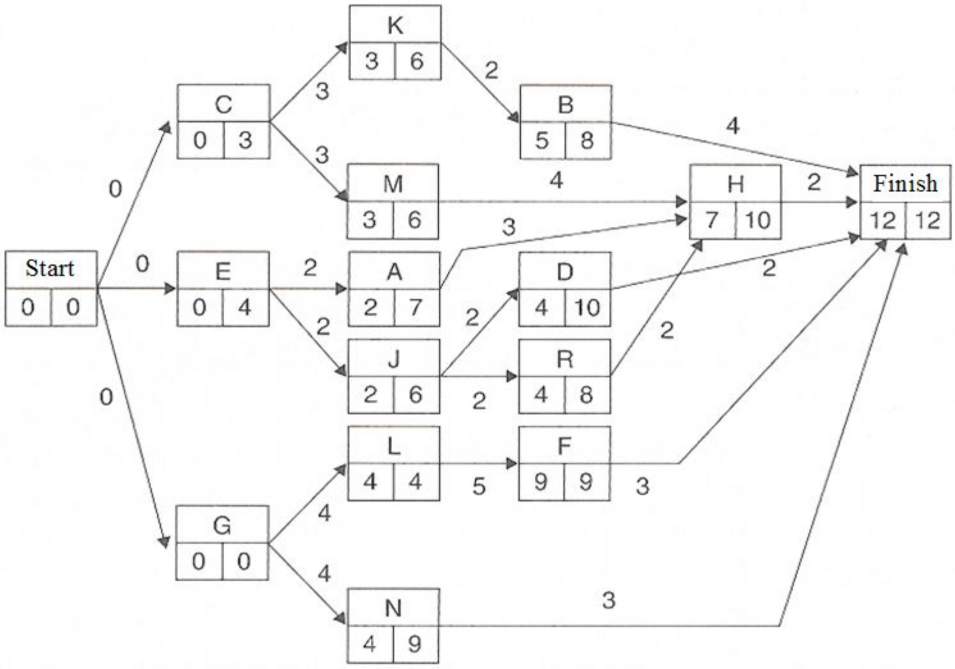
A "critical path" is a path of maximum length between the two extreme nodes (milestones). It may have possibly be more than one of the same length. Any task located on a critical path can not be delayed without affecting the total duration of a project. In other words, it has zero "total slack" (we then also say so that its early start finish date is strictly equal to late finish date). Furthermore, we also define in project management the "free slack" that indicates the time over which a task can slide without moving/impacting the successor task. The free slack is calculated as the difference between the date of earliest start of a task summed of its duration and the late start of the successor task. By construction the free slack is always small or equal tot the total slack.

Let us take for example a project that consists of the following tasks:

Tasks	Predecessor Tasks	Duration
A	E	3
B	K,C	4
C	-	3
E	E,J	2
E	-	2
F	G,L	3
G	-	4
H	A, M, R	2
J	E	2
K	C	2
L	G	5
M	C	4
N	G	3
R	J	2

Table 8.8: **Data for critical path example**

The valued associated directed graph corresponding to this table once the definition of the critical path applied is the following using the start dates (this method of calculation is named "Potential Metra Method"):



Start
0 0
C
0 3
E
0 4
G
0 0
K
3 6
M
3 6
A
2 7
J
2 6
L
4 4
N
4 9
B
5 8
D
4 10
R
4 8
F
9 9
H
7 10
Finish
12 12

Figure 8.316: **PERT (Program Evaluation Review Technique) diagram**

We see well in this graph that the finite set of tasks $\{\text{Start}, G, L, \text{Finish}\}$ are critical.

A great tool for using such graphs is (among others) Microsoft Project whose the corresponding Gantt diagram for the example above is:

		Task Name	Duration	Free Slack	Total Slack
1		Début	0 days	0 days	0 days
2		A	3 days	2 days	5 days
3		B	4 days	3 days	3 days
4		C	3 days	0 days	3 days
5		D	2 days	6 days	6 days
6		E	2 days	0 days	4 days
7		F	3 days	0 days	0 days
8		G	4 days	0 days	0 days
9		H	2 days	3 days	3 days
10		J	2 days	0 days	4 days
11		K	2 days	0 days	3 days
12		L	5 days	0 days	0 days
13		M	4 days	0 days	3 days
14		N	3 days	5 days	5 days
15		R	2 days	1 day	4 days

Figure 8.317: **Same graph but seen in Microsoft Project 97**

D24. A "cycle" is a simple path looping on itself. A graph in which there is no cycles is known as "acyclic".

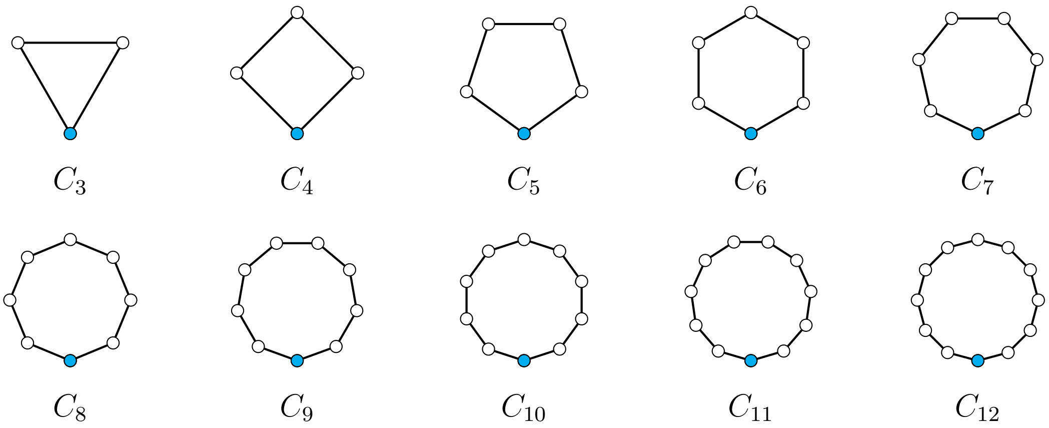

Figure 8.318: **Examples of cyclic graphs**

Non-connex acyclic graphs made of trees are an interesting class of graphs with remarkable properties and a name: "forests" (a term often used in computer networks).

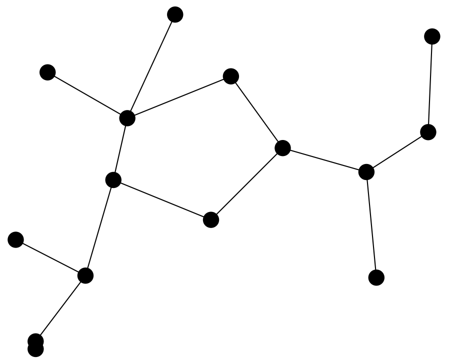

Figure 8.319: **Example of a connex graph containing a cycle**

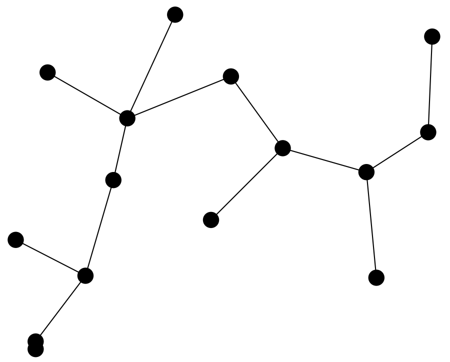

Figure 8.320: **Example of a connex graph containing no cycles**

Below an example of forest (composed of trees, each tree being connex but the whole forming an acyclic and non-connex graph):

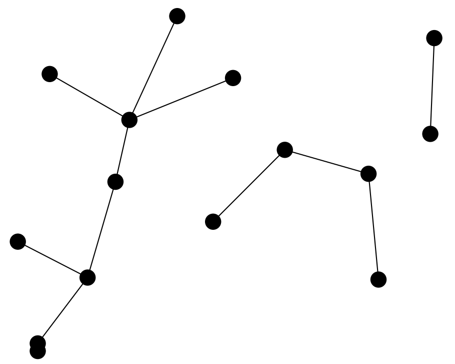

Figure 8.321: **Example of a forest (3 connex graphs)**

Thus we see that a forest is a graph whose components are trees. The vertices of degree 1 are named "leaves" of the tree.

Properties:

P1. If in a graph G is any vertex is of degree greater than or equal to 2, then G has at least one cycle (trivial).

> **Remark**
>
> This simple property implies that a graph without cycle without graph has at least one vertex of degree 0 or 1.

P2. An acyclic graph G with n vertices has at most $n-1$ edges as we already know.

D25. An "Eulerian cycle" is a cycle passing once and only once by each edge of the graph and returning to the starting point (we will see further properties required by a graph for such a cycle exists on it) and a graph having an eulerian cycle is named "Eulerian graph".

D26. A "Hamiltonian cycle" is a simple cycle through all the vertices of the graph once and only once and a graph having an eulerian cycle is named "Hamiltonian graph". For a Hamiltonian cycle, the graph must be connex and must not have any single node.

To better understand the difference between the two previous definitions the reader can see in the figure below some graphs that are Eulerian and Hamiltonian, Eulerian but not Hamiltonian and so on... (the four possibilities):

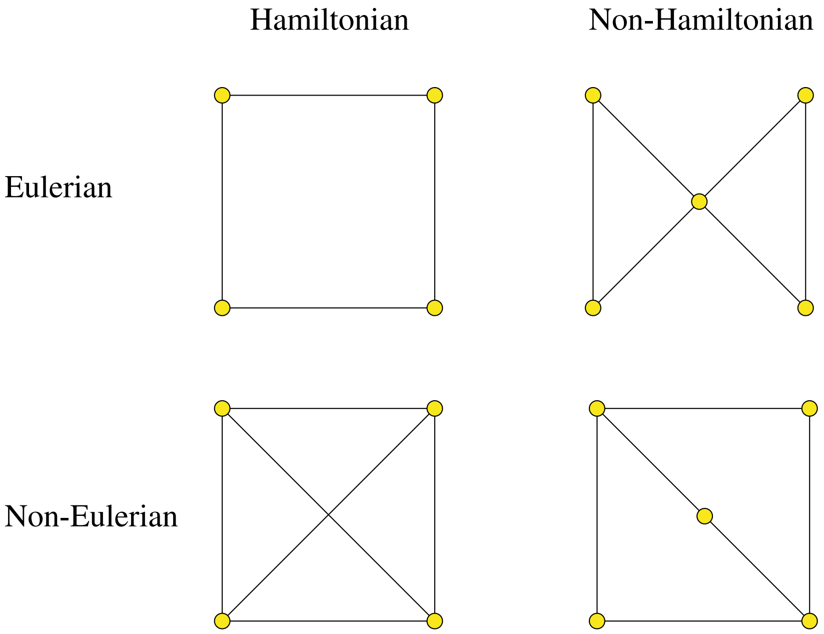

Figure 8.322: **Example of Hamiltonian or Non-Hamiltonian graphs**

It is appropriate now to open a parenthesis (for straws ...) on one of the most famous problem in graph theory: Königsberg bridges.

Leonhard Euler, liked to take a walk in his city of Königsberg. Following the legend he liked especially to walk through seven bridges that cross the river. Age coming (mathematical knowledge too ...), he wondered if without sacrificing his walk, he could shorten the length of his walk by crossing each bridge only once. This problem is probably one of the oldest known one in graph theory: that the existence of a chain passing once and only once by each edge (sadly today only four bridges remain standing).

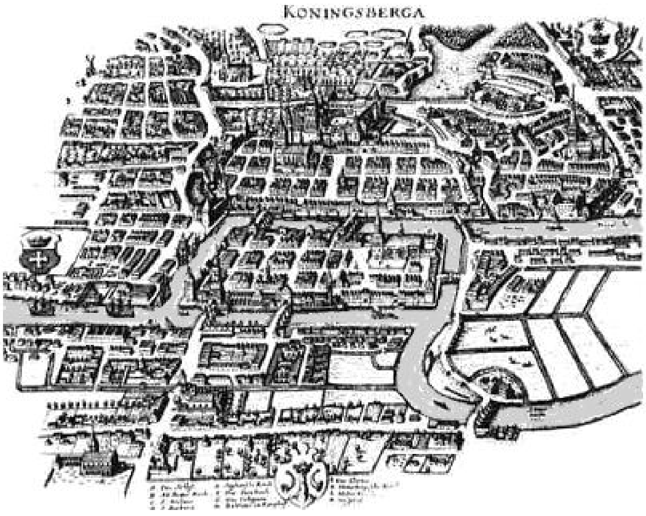

Figure 8.323: **Antique map of the city of Königsberg**

The river divides the city of Königsberg in four parts: a, b, c, d. Each bridge connects two such parties. Then we can represent our problem by a graph with four vertices, wherein each edge represents one of the seven bridges of Königsberg. In this example the graph is not a simple graph:

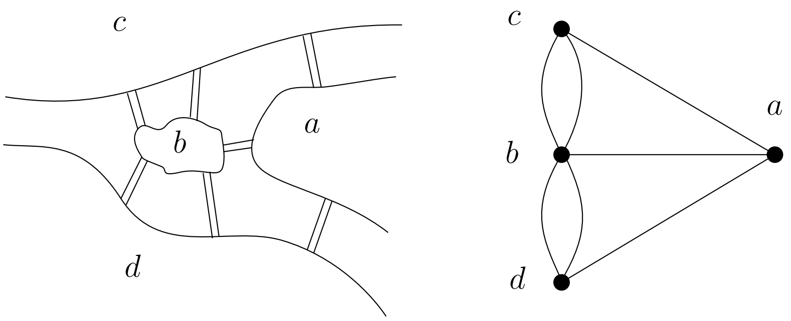

Figure 8.324: **Königsberg equivalent graph**

The question here is whether the graph is Eulerian or not? If our problem the obtained graph is Eulerian, we need to exhibit an Euler cycle, which does not seem easy. But if it is not? Euler gave a strong characterization of Eulerian graphs given by the following statement:

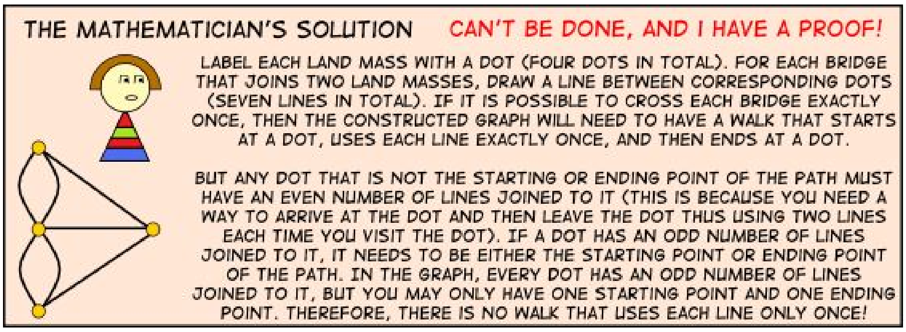
Theorem 8.30 (Euler Theorem)**.** A graph is Eulerian if and only if it is connex and all vertices have even degree (so there is an even number of edges that arrive on each vertex of which half of them used to arrive at the vertices, the others to leave it) except for maximum two (these two exceptions being the vertice of departure and this of arrival).

Specifically for a connex graph:

- The graph has no odd vertices, then it is Eulerian (and the chain is cyclic).
- The graph can have only one odd vertices from the property (already stated above) that in a graph, the vertices having odd order is always in even.
- If the graph has two odd vertices, then these vertices are the ends of the Eulerian cycle.

As corollary we have that a graph have more than two odd vertices never have an Eulerian cycle.

With this characterization (as we will prove it just after), the vertices a, b, c, d being of odd order, we know immediately that it is impossible to walk cross all the Königsberg bridges in only one time during a walk.



THE MATHEMATICIAN'S SOLUTION CAN'T BE DONE, AND I HAVE A PROOF!

LABEL EACH LAND MASS WITH A DOT (FOUR DOTS IN TOTAL). FOR EACH BRIDGE THAT JOINS TWO LAND MASSES, DRAW A LINE BETWEEN CORRESPONDING DOTS (SEVEN LINES IN TOTAL). IF IT IS POSSIBLE TO CROSS EACH BRIDGE EXACTLY ONCE, THEN THE CONSTRUCTED GRAPH WILL NEED TO HAVE A WALK THAT STARTS AT A DOT, USES EACH LINE EXACTLY ONCE, AND THEN ENDS AT A DOT.

BUT ANY DOT THAT IS NOT THE STARTING OR ENDING POINT OF THE PATH MUST HAVE AN EVEN NUMBER OF LINES JOINED TO IT (THIS IS BECAUSE YOU NEED A WAY TO ARRIVE AT THE DOT AND THEN LEAVE THE DOT THUS USING TWO LINES EACH TIME YOU VISIT THE DOT). IF A DOT HAS AN ODD NUMBER OF LINES JOINED TO IT, IT NEEDS TO BE EITHER THE STARTING POINT OR ENDING POINT OF THE PATH. IN THE GRAPH, EVERY DOT HAS AN ODD NUMBER OF LINES JOINED TO IT, BUT YOU MAY ONLY HAVE ONE STARTING POINT AND ONE ENDING POINT. THEREFORE, THERE IS NO WALK THAT USES EACH LINE ONLY ONCE!

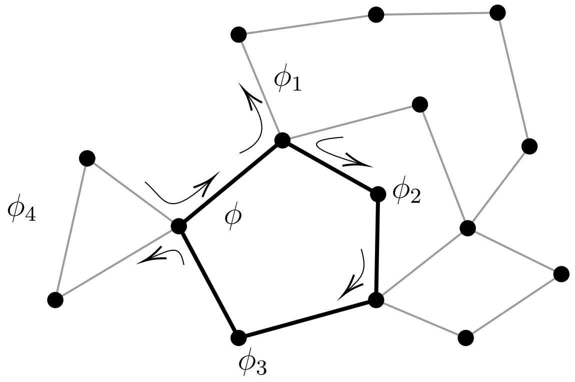
Proof 8.30.1. The proof will be done if three steps:

(a) Let us suppose that a graph G is Eulerian. Then there exists a chain c browsing once and only once each edge (until then it's easy). Of course, in the case of a chain, the peaks being located at the ends of the chain are of odd order and are only two.

(b) Consider now a vertex x and let us suppose this time not a Eulerian graph but an Euler cycle. During the course of this cycle, each time we go through the vertex x, we find ourselves at the starting point and to perform a new round two edged are available to us (indeed the path can be walked in two direction since the graph is undirected!). The vertex x is the of even order and can be defined anywhere in the cycle, hence the fact that all the vertices are of even degree.

(c) Conversely, consider a connected graph G whose vertices are all of even degree. We will show by induction on the number of edges that G is then Eulerian:

- If G is reduced to a single isolated vertex, it is obviously Eulerian. Otherwise all the vertices of G are of degree greater or equal to 2. This implies that there is a cycle ϕ on G:
- Consider the partial graph H consisting of the edges outside the cycle ϕ. The vertices of H are also of even degree, the cycle containing an even number of edges incident to each vertex. By induction each connex component H_i of H is an Eulerian graph, and so has an Eulerian cycle ϕ_i. To rebuild an Euler cycle on G, we only need to merge the cycle ϕ the with different cycles ϕ_i. For this, we travel the cycle ϕ from an arbitrary vertices; when we meet for the first time a vertices x from H_i, we substitute it the cycle ϕ_i. The resulting cycle is an Euler cycle in G, the cycle ϕ and the cycles ϕ_i form a partition of the edges.



■ Q.E.D.

Remark

This principle of decomposing a graph into connex graphs and summing them permits to build a recursive algorithm for determining if a graph is Eulerian or not.

D27. Two graphs G and G' are "complementary graphs" when they satisfy the following conditions:

(a) They have the same set of vertices.

(b) Two vertices x, y that are neighbours in G are not neighbours in G'.

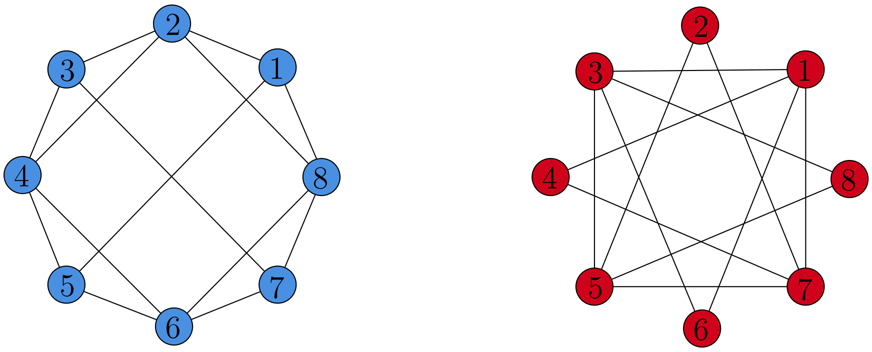


Figure 8.325: **Example of complementary graph**

A "self-complementary" graph is a graph which is isomorphic to its complement. The simplest non-trivial self-complementary graphs are the 4-vertex path graph and the 5-vertex cycle graph.

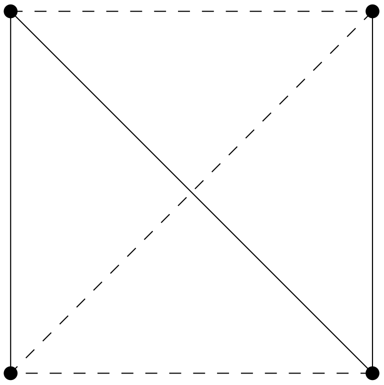

Figure 8.326: **Example of self-complementary graph**

D28. A "bipartite graph" is a graph $K_{p,q}$ such that we can partition the set of all its vertices into two classes cardinal of p and q respectively so that each edge has one end in each of the two classes.

✍Example:

Here is a representation of a classical bipartite graph $K_{3,3}$. It is the famous problem of the supply of three houses from three supplier (water, electricity, gas) without the right of alignment of services (using same "pipelines"). We immediately see that this graph is non-planar.

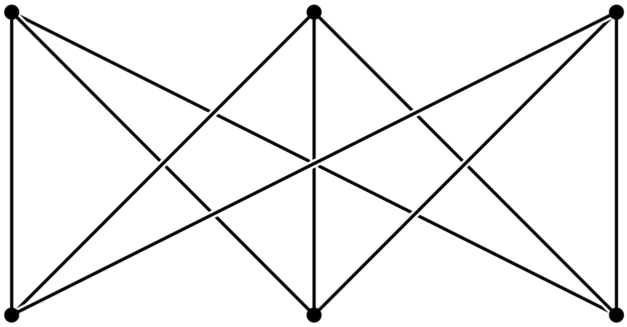

Figure 8.327: **Example of a $K_{3,3}$ bipartite graph**

Remark

The complete bipartite graph $K_{p,q}$ is a graph with $n=p+1$ vertices and configured in such a way that each vertex of a class is adjacent to all the vertices of the other and only thereto.

D29. Two graphs are "isomorphic graphs" if there exists a bijection of f from X into X' such that for any vertices x and y of G:

$$x \text{ adjacent to } y \text{ in } G \leftrightarrow f(x) \text{ adjacent to } f(y) \text{ in } G' \tag{8.8.21}$$

We also say that f is an "isomorphism of G on G'".

More formally, an isomorphism of graphs G_1 and G_2 is a bijection $f:V(G_1)\leftrightarrow V(G_2)$ that preserves adjacency. That is to say:

$$u \sim_{G_1} v \leftrightarrow f(u) \sim_{G_2} f(v) \tag{8.8.22}$$

For example on the figure below we have three isomorphic graphs:

	1	**2**	**3**	**4**	**5**
1			1	1	
2				1	1
3	1				1
4	1	1			
5		1	1		

	1	**2**	**3**	**4**	**5**
1		1			1
2	1		1		
3		1		1	
4			1		1
5	1			1	

	1	**2**	**3**	**4**	**5**
1		1		1	
2	1				1
3				1	1
4	1		1		
5		1	1		

Figure 8.328: **Isomorphic graphs with their adjacency matrix**

Caution!!! Sometimes we talk about graphs equivalence "to a given isomorphism". This means more clearly, that at the exception of a single violation among the set of all edges, that the graphs are isomorphic.

If there exists a bijection of f of X into itself such that:

$$x \text{ adjacent to } y \text{ in } G \leftrightarrow f(x) \text{ adjacent to } f(y) \text{ in } G \tag{8.8.23}$$

then we say that f is an "automorphism of graph" in G (by permutation of the vertices there are many possible examples ...).

As the isomorphism in the case of graphs go from one set to another of the same size n (n to n mapping), the number of different possible bijections is (see section Probabilities page 525):

$$n! \tag{8.8.24}$$

This means there is a maximum of $n!$ graphs which can be grouped in a same equivalence class. Consequently, there exists at least (lower bound) the ratio of the total n of vertices on the cardinal majorated by the greatest possible equivalence class (but not necessarily existing!):

$$N=\frac{2^{\frac{n(n-1)}{2}}}{n!} \tag{8.8.25}$$

Using the gross majoration $n!<n^n$, we have:

$$N>\frac{2^{\frac{n(n-1)}{2}}}{n^n} \tag{8.8.26}$$

Therefore:

$$\log_2(N)>\frac{n(n-1)}{2}-n\log_2(n) \tag{8.8.27}$$

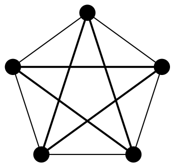
Given:

$$\log_2(N)>\frac{n^2}{2}\left(1-\frac{1}{n}-\frac{2\log_2(n)}{(n)}\right) \tag{8.8.28}$$

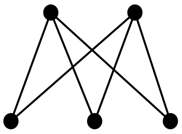
Thus, when n approaches the infinity, $\log_2(N)$ admits a lower bound of order n^2.

The reader should also keep in mind that some graphs are used more than other, and get special names:

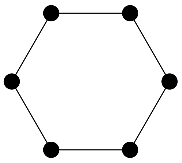
- K_n: The complete graph on n vertices
- $K_{m,n}$: The complete bipartite graph with sets of m and n vertices
- C_n: The cycle on n vertices, just one big loop
- P_n: The path on n vertices, just one long path



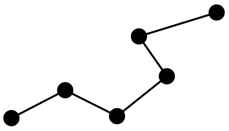
K_5



$K_{2,3}$



C_6



P_6

8.8.2 Graph Adjacency Matrix

Formally, a graph is also a set on which we have defined a binary, anti-reflexive (no element is related to itself) and symmetric (if x is related to y, then y is related to x) relation. The graph structure may then seem particularly poor.

But we can also associate to a graph G vertices $x_1,\ldots,x_n$ a square matrix M of dimensions $m\times n$ named the "adjacency matrix" of the graph and whose elements are 0 or 1. Denoting by m_{ij} the term located at the intersection of row number i (representing the vertices x_i) and column j (representing the vertices x_j), M is defined as:

$$m_{ij}=1 \quad \text{if and only if}\, x_i,x_j \text{ are adjacents} \tag{8.8.29}$$

Remark

We also know that graphs can be represented by matrices in the context of the study of Markov chains in the field of probabilities (see section Probabilities page 537).

Let us see an example both abstract but also easily applicable to many fields of industry, sociology and biology (there is also application for the adjacency matrix in Text Mining as you can see in the `R` companion book). Consider the following directed graph and observe that it is not symmetrical nor antireflexive:

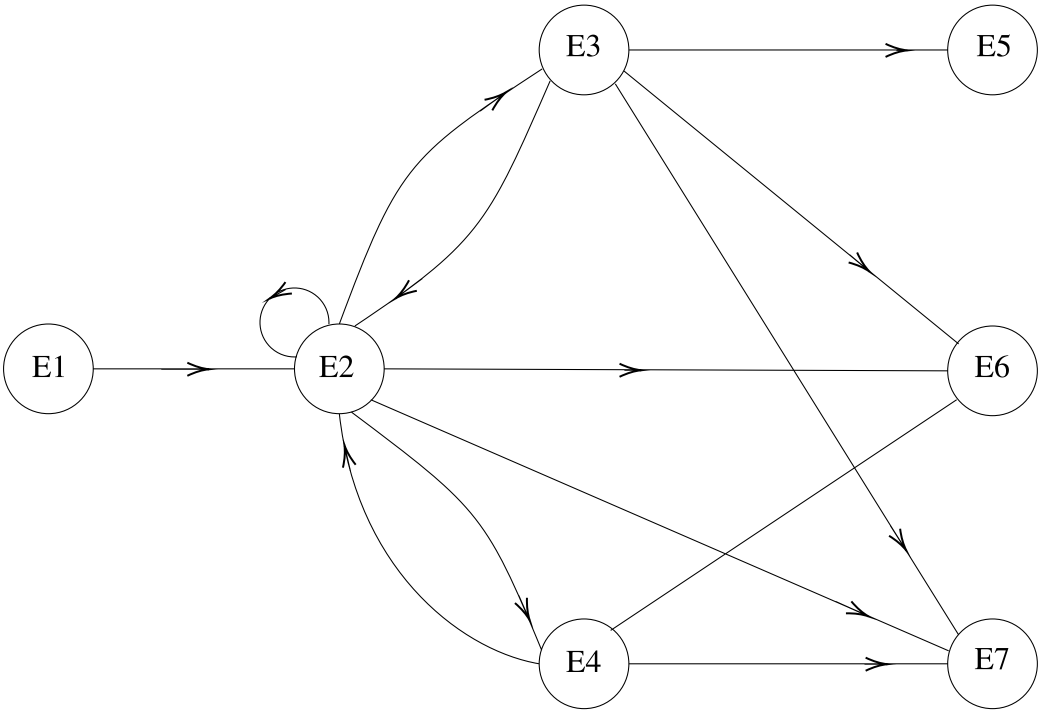


Figure 8.329: Example of Markov chain (nor antireflexive or symmetric)

And as we just say we can represent this diagram (connected, and oriented graph) in the form of a table in which we denote by "1" a possible transition from the state mentioned at the top of the column to the state mentioned at the beginning of the row and "0" otherwise:

↗	E1	E4	E2	E3	E5	E7	E6
E1.	0	0	0	0	0	0	0
E4.	0	0	1	0	0	0	0
E2.	1	1	1	1	0	0	0
E3.	0	0	1	0	0	0	0
E5.	0	0	0	1	0	0	0
E7.	0	1	1	1	0	0	0
E6.	0	1	1	1	0	0	0

Table 8.9: **Adjacency matrix of the connected graph**

It is essential to fully understand the meaning of the values in this table! But at this level of the book that should not pose major difficulties to the reader.

Now let us evaluate the number of ways to go:

1. From E2 to E2 in two stages
2. From E3 to E4 in two stages
3. Form E2 to E7 in two stages

It is easy in the particular case above to count these possibilities. But in the case of a more complex graph it becomes difficult or even impossible for a human being within a reasonable time (and also for some computer at this time).

We have to use then the following theorem:

Theorem 8.31. Given an orient graph with $x_1, x_2, \ldots, x_n$ vertices and of adjacency matrix:

$$M = (m_{ij}) \tag{8.8.30}$$

For any integer k, then the number of paths of length k of vertices x_1 to a vertices x_j is given by:

$$M^k = m_{ij}^{(k)} \tag{8.8.31}$$

where the exponent of M, denotes the power k of the adjacency matrix.

Proof 8.31.1. Let us perform an induction on k:

$$m_{ij}^{(1)} = m_{ij} \tag{8.8.32}$$

designates the number of paths going from x_i to x_j (where i and j can be equal). Let us suppose the result true for the integer $k-1$, with $k \geq 1$ as:

$$M^k = M^{k-1} M \tag{8.8.33}$$

we then have (by construction of matrix multiplication):

$$m_{ij}^{(k)} = \sum_{I=1}^{n} m_{ij}^{(k-1)} m_{lj} \tag{8.8.34}$$

By induction hypothesis, $m_{il}^{(k1)}$ is the number of paths of length $k-1$ from x_i to x_l and m_{lj} is, we know it (by construction!), the number of paths of length 1 from x_l to x_j and in particular it is equal to 1 if (x_i, x_j) is an edge of the graph and equal to 0 otherwise!

So the product:

$$m_{il}^{(k-1)}m_{lj} \tag{8.8.35}$$

gives for a given value of l the number of paths of length k from x_i to x_j whose last edge is (x_l, x_j).

The sum:

$$\sum_{l=1}^{n} m_{il}^{(k-1)}m_{lj} \tag{8.8.36}$$

therefore gives all the possibilities (paths) of length k from x_i to x_j regardless of the starting point of the last edge!

■ Q.E.D.

Thus, in our example, the adjacency matrix M is given by:

$$M=\begin{bmatrix}0&0&0&0&0&0&0\\0&0&1&0&0&0&0\\1&1&1&1&0&0&0\\0&0&1&0&0&0&0\\0&0&0&1&0&0&0\\0&1&1&1&0&0&0\\0&1&1&1&0&0&0\end{bmatrix} \tag{8.8.37}$$

and is neither symmetric or antireflexive as we have already mentioned.

So if we carry this matrix at the power of k, each component $m_{ij}^{(k)}$ will give all possibilities (paths) of length k going from x_i to x_j Thus we have for example with $k=2$:

$$M^2=\begin{bmatrix}0&0&0&0&0&0&0\\1&1&1&1&0&0&0\\1&1&3&1&0&0&0\\1&1&1&1&0&0&0\\0&0&1&0&0&0&0\\1&1&3&1&0&0&0\\1&1&3&1&0&0&0\end{bmatrix} \tag{8.8.38}$$

using for example the function `MMULT( )` available in most spreadsheet softwares.

We then have the answer to all our three initial questions by reading the above matrix:

1. From E2 to E2 in two stages there are 3 possibilities

2. From E3 to E4 in two stages there is 1 possibility
3. From E2 to E7 in two stages there are 3 possibilities

It is possible to gain some time in such calculations. If we denote C_i, the i-th column of the matrix M, then:

$$MC_i = M_i^2 \tag{8.8.39}$$

So we always get the number of paths of length k from a given starting point corresponding to the column i.

This example has a very interesting approach in some areas studying the behaviour of individuals in different situations (shopping, tourisms, accidents, etc.).

If instead of writing in the matrix M the number of possible paths from one vertices to another, we write the probability (part) of the total number of individuals who go from one vertices to reach another one we have for example (in practice the values are imposed by experimental observation!) the following matrix:

$$M = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.094 & 0 & 0 & 0 & 0 \\ 1 & 0.954 & 0.662 & 0.75 & 0 & 0 & 0 \\ 0 & 0 & 0.218 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.175 & 1 & 0 & 0 \\ 0 & 0.034 & 0.017 & 0.035 & 0 & 1 & 0 \\ 0 & 0.012 & 0.009 & 0.04 & 0 & 0 & 1 \end{bmatrix} \tag{8.8.40}$$

which is already the stochastic transpose matrix of the visible graph below (according to the theory of Markov chains we saw in the section of Probabilities that we need to take the transpose of the stochastic matrix to calculate the probabilities of states).

Considering that these probabilities do not change over time, then we have a homogeneous Markov chain (without cycles). We then see that:

1. The sum of the transition probabilities going from each vertices (state) must always logically be equal to 1 (which we already mentioned in the section of Probabilities)
2. Everyone start from the first vertices E1
3. Some stagnate (stop) at some stage
4. Those arriving at an end stage E5, E6 or E7 stay there and do not retrace their steps (absorbing states).

The equivalent graph is therefore:

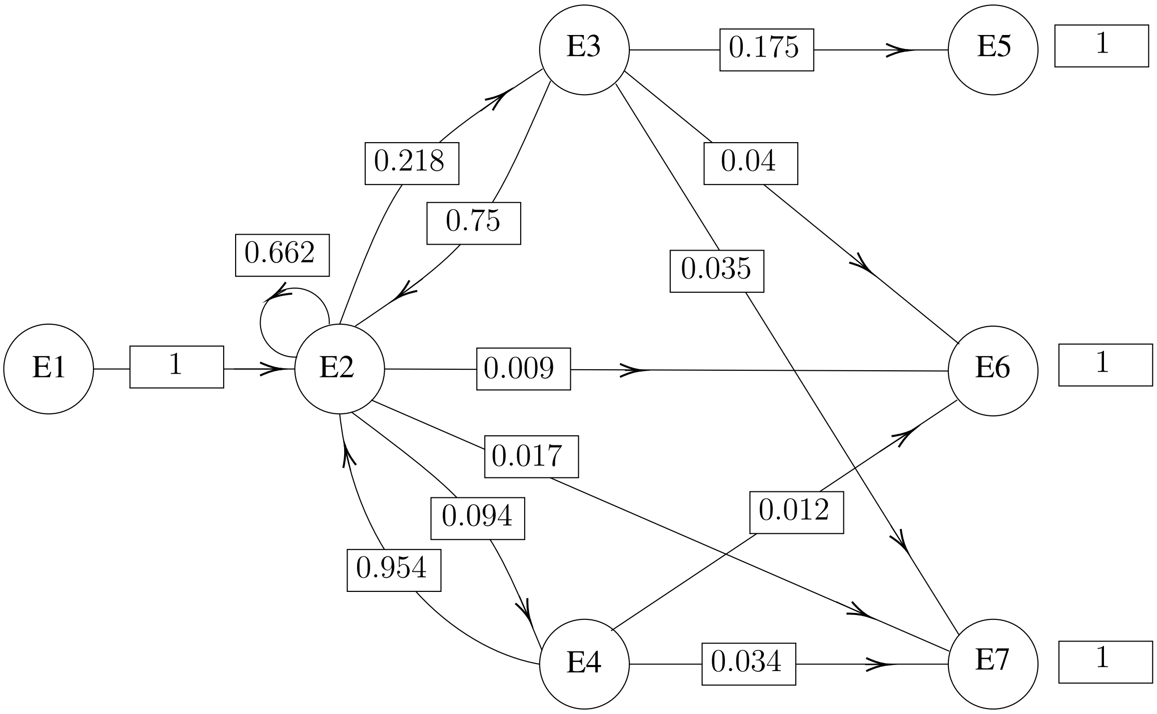

Figure 8.330: **Markov probabilistic transition graph**

By denoting N (instead of M to avoid confusion) the matrix constructed from the graph above we see that C_i is if one of the columns of the matrix M then for example:

$$NC_1 = T_1 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.094 & 0 & 0 & 0 & 0 \\ 1 & 0.954 & 0.662 & 0.75 & 0 & 0 & 0 \\ 0 & 0 & 0.218 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.175 & 1 & 0 & 0 \\ 0 & 0.034 & 0.017 & 0.035 & 0 & 1 & 0 \\ 0 & 0.012 & 0.009 & 0.04 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0.094 \\ 0.662 \\ 0.218 \\ 0 \\ 0.017 \\ 0.009 \end{bmatrix} \tag{8.8.41}$$

gives the sum of the transition probabilities that what goes from E1 arrives 2 in respectively E1(0), E2(0.662), E3(0.218) ... (the distribution of the initial vector may be any as long as the sum of column of values is equal to 1)!

If we then multiply again:

$$NT_1 = T_1 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.094 & 0 & 0 & 0 & 0 \\ 1 & 0.954 & 0.662 & 0.75 & 0 & 0 & 0 \\ 0 & 0 & 0.218 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.175 & 1 & 0 & 0 \\ 0 & 0.034 & 0.017 & 0.035 & 0 & 1 & 0 \\ 0 & 0.012 & 0.009 & 0.04 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0.094 \\ 0.662 \\ 0.218 \\ 0 \\ 0.017 \\ 0.009 \end{bmatrix} = \begin{bmatrix} 0 \\ 0.062 \\ 0.691 \\ 0.144 \\ 0.038 \\ 0.039 \\ 0.025 \end{bmatrix} \tag{8.8.42}$$

gives the sum of the transition probabilities that what goes from E1 arrives 3 in respectively E1(0), E2(0.691), ... and so on. We can therefore know what is the probability that an individual arriving on E2 can arrive to one of the terminal nodes (E5, E6 or E7) on a number of finite step.

Remark

Remember that the sum of the probabilities of the resulting columns T is always equal to 1 for the transpose of the stochastic matrix.

Continuing a long time as well ... we find that the equilibrium measurement π that satisfies (see section Probabilities page 540):

$$P^T\pi = \pi \tag{8.8.43}$$

is:

$$\pi = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0.45 \\ 0.32 \\ 0.23 \end{bmatrix} \tag{8.8.44}$$

regardless of the distribution of the starting vector. Property named "ergodic" in the field of Markov chains.

Which means 45% probability of being in E5, 32% probability of being in E7 and 23% probability of being in E6. Another way to look at it is to say that if a cohort of 100 individuals start at node E1 with constant probability in time between the various states transitions, the equilibrium we will have is 45 people in E5, 32 people in E7 and 23 people in E6.

8.8.3 Categories

The introduction of categories through the "category theory" by Eilenberg and MacLane in 11942 (holocene calendar) was to transform difficult problems of topology in more affordable algebra problems. Later, the theory of categories has grown significantly, both for itself and for its applications in the most diverse fields of mathematics (e.g. differential geometry). Although some of its autonomous development has sometimes been criticized, categories are now recognized as a powerful language to develop a universal semantics of mathematical structures. They are also used in logic and more recently in physics, and a fruitful collaboration seems to develop between IT and categoricians.

Definitions (#8.8.398):

D1. Intuitively a "category" is just a directed graph on which we have given a law to compose consecutive arrows, satisfying certain axioms.

D2. An "oriented graph" is formed by a set of nodes of graph, with links between them, represented by arrows from a node A to a node B, what we denote by $f: A \mapsto B$. We say then that A is the "source" of the arrow, and B and its "goal". There may be several arrows having same source and the same goal (we say then that they are "parallel") and there can be "closed" arrows, which source and target coincide.

D3. Two arrows f, g are say to be "consecutive arrow" if the target of the first is also the source of the second:

$$f : A \to B \qquad g : B \to C \tag{8.8.45}$$

then we say that they form a path of length 2 from A to C.

A category is then a graph in which we define a composition of arrows, associating to any path (f, g) of length 2 from A to C an arrow of the graph from A to A, named "composed of the path", and denoted fg:

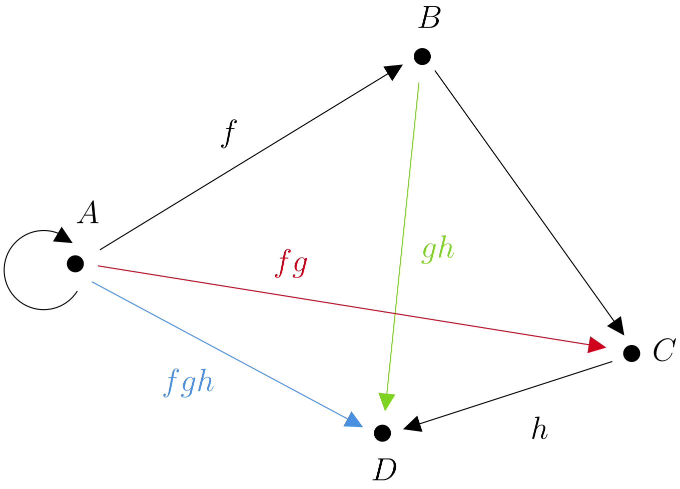

Figure 8.331: Example of graph of categories

This composition satisfies the following axioms:

A1. Associativity: If fgh is a path of length 3, the both compositions $f(gh)$ and $(fg)h$ that we deduce are associative. It follows that to any path of length n is also associated only a single composition of vertices (invariance of the path).

A2. Identities: At any node A is associated a closed arrow from A to A, obviously named "identity" of A and denoted Id_A, from which the composition with an arrow of source or target A is equal to this other arrow.

More generally, a path (of length n) from A to A_n is a sequence of n consecutive arrows:

$$f_1 : A \to A_1, f_2 : A_1 \to A_2, \ldots, f_n : A_{n-1} \to A_n \tag{8.8.46}$$

Remarks

R1. The graph nodes are named "objects" of category and the arrows the "morphisms" (or simply "links") within the framework of category theory.

R2. An arrow f is an isomorphism (see section Set Theory page 443) if there exists an arrow g (named "inverse") such that the compositions fg and gf are identities (this inverse is therefore unique).

Thus, a category is formed by objects (the nodes of the graph) and by the links between them (the arrows or morphisms), but the essential idea is to emphasize the links relatively to the objects. In fact, the success of the categories in the most varied fields is due to the quantity of information on objects that can be inferred from the mere consideration of links and operations on them, regardless of the nature and anatomy of these objects.

In the next few lines, we will explain how to read the directed graphs we can sometimes encounter in math books. This will be a good example of category theory, because we have already encountered such graphs without describing them in the section Numbers and Cryptography for example.

For simplicity we will explain these graphs when the basic objects are sets (which is the most common case in this whole book anyway actually).

Let us consider three sets A, B, and C and three applications such that:

$$f:A\mapsto B, g:A\mapsto C, h:B\mapsto C \tag{8.8.47}$$

and let us rewrite it as following:

$$f:A\rightarrow B, g:A\rightarrow C, h:B\rightarrow C \tag{8.8.48}$$

We can therefore consider the applications f, g and h as arrows that connect the objects (sets) A, B, and C to form a triangle:

$$\begin{tikzcd}
A \arrow[r, "g"] \arrow[d, "f"'] & C \\
B \arrow[ur, "h"'] &
\end{tikzcd}$$

Where obviously $g=h\circ f$ or more explicitly for those that have forgotten the signification of this notation that for any $a\in A$ we have $h(f(a))=g(a)$.

Definition (naive version #399): We say that an oriented graph is a "commutative diagram" if all the paths we take to get from one object (set) to another one represent the same application.

Or let us consider:

$$f:A\rightarrow B, g:B\rightarrow C, h:A\rightarrow C \tag{8.8.49}$$

and such that each application f,g,h has its Kernel that is equal to the set of neutral elements of the starting set. Therefore:

$$\begin{tikzcd} A \arrow[loop left, "1_A"] \arrow[r, "f"] \arrow[dr, "g \circ f"'] & B \arrow[loop right, "1_B"] \arrow[d, "g"] \\ & C \arrow[loop right, "1_C"] \end{tikzcd}$$

We can complicate almost without limits such diagrams considering more sets and arrows (applications) connecting them. For example:

$$\begin{tikzcd} A \arrow[r, "g"] \arrow[d, "f"'] & C \arrow[d, "r"] \\ B \arrow[r, "h"'] & D \end{tikzcd}$$

This diagram is commutative if and only if $h \circ f = r \circ g$.

Remarks

R1. Usually in the mathematical literature such diagrams are implicitly commutative.

R2. As already mentioned, the objects of these diagrams can more generally be groups, rings, fields, topological space, etc. In these cases, the arrows are no longer any applications but group homomorphisms, or ring homomorphisms, continuous applications, etc.

8.9. Knot Theory

René Descartes had imagined a system of the World, when the universe was animated by vortices. At the end of 118th century (holocene calendar), Peter Guthrie Tait et William Thomson Kelvin have resurrected this theory, and interpreted the chemical bonds imagining knotted molecules that interlace.

Remarks

R1. The name "Knots theory" that has emerged in the scientific community is quite unfortunate. Some (French) mathematicians rightly use instead the name of "theory of intertwining and braids" which is more correct and general (since a node is interlaced with several components).

R2. Most of the text and figures below is a reproduction, with agreement, of Professor Michael Eisermann course from the University of Stuttgart (`http://www.igt.uni-stuttgart.de/eiserm`).

The mathematical knot theory was pioneered by the work of Charles Newton Little and Thomas Kirkman who tried to give a basis for the physical ideas of Peter Guthrie Tait et William Thomson Kelvin. The first nodes classifications using a wire image of the nodes, without thickness, and a planar projection, as the shadow cast on a screen. One immediately noticeable character concerns crossings where we distinguish the strand above and strand below. The cannages, or braiding strips are based on the consideration of the crossings, and the number of such intersections will be the first classifying element.

8.9.1 Braids Representation

An example of braid (set of strands) and the corresponding string (a string is a braid that was closed):

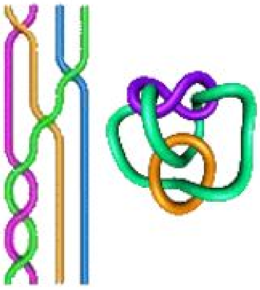

Figure 8.332: **Braid and corresponding string (node diagram)**

Let us focus on the braid to the left of the figure above to begin and let us ask ourselves what would be the best way of putting things in order to compare braids? Let us first attempt with the following representation of a particular braid:

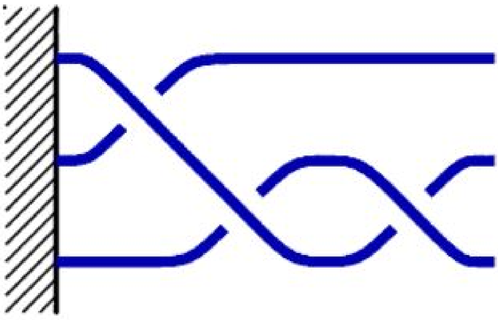

Figure 8.333: **Particular presentation of a braid**

As the strands of a braid are flexible and can move, we notice immediately that this representation has a problem: all the braids are equal. Effectively:

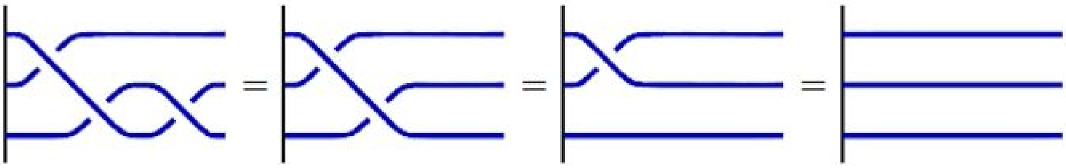

Figure 8.334: **Example of the problem of the braid representation**

A better model then is perhaps to secure the ends of both sides:

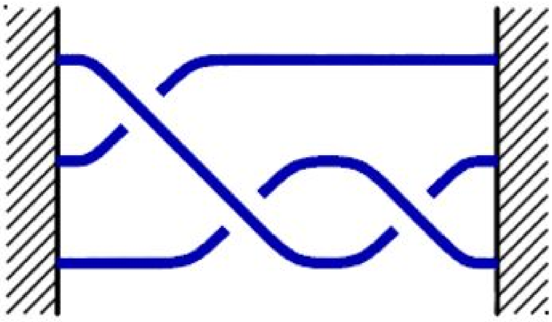

Figure 8.335: **Other choice of representation**

Of course, with this model the middle strands may still move as below and the braid remains invariant:

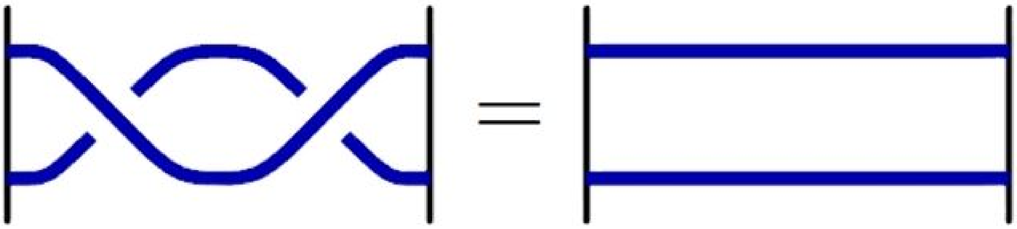

Figure 8.336: **First example of invariant braid**

or otherwise as this:

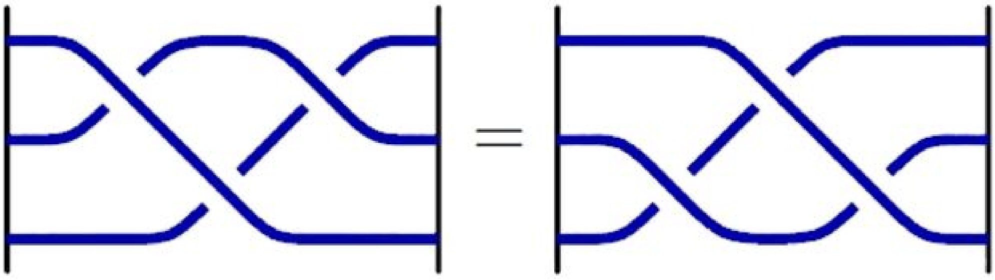

Figure 8.337: **Second example of invariant braid**

We can also translate the crossings and the braid remains invariant:

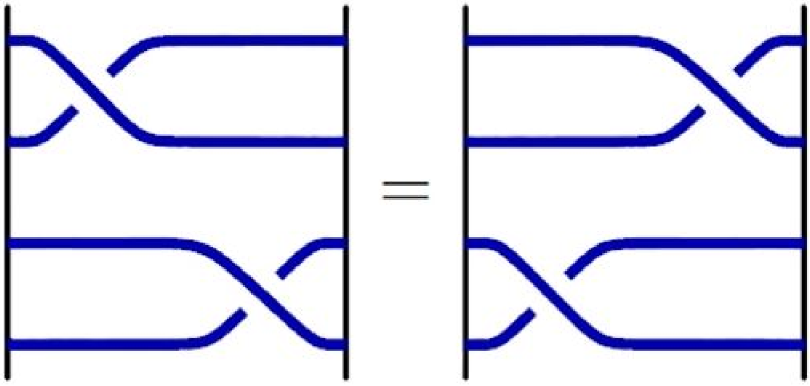

Figure 8.338: **Translation of crossing and preserving the trivial invariance**

The length is not a variable in this model:

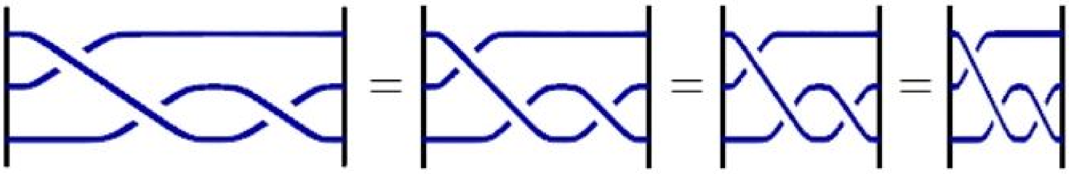

Figure 8.339: **Length invariance**

8.9.1.1 Braids Group

If we define the multiplication of two braids as the operation that consists schematically to:

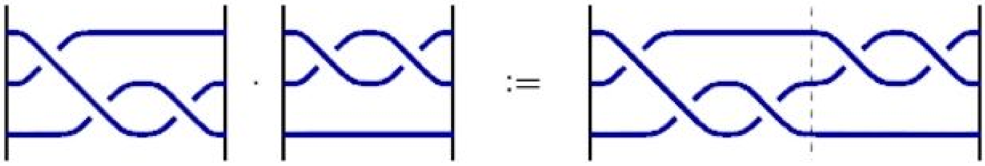

Figure 8.340: **Example of multiplication of two braids**

We can ask ourselves if this is a type of commutative group?

Remember before that we have defined the group structure in the section of Set Theory as follows: We refer to a set by the term "group" if its components meets the three conditions of what we name "internal law group ", defined below:

$$(G,\star)\text{ is a group if}=\begin{cases}\star\text{ is associative}\\ \text{it exists for }G\text{ a neutral element for }\star\\ \text{any elelement of }G\text{ has a symetric for }\star\end{cases}\tag{8.9.1}$$

If furthermore, the internal law is also commutative, then we say that the group is an "abelian group" or simply "commutative group".

1. Let us start with the first check. Is this representation is associative?:

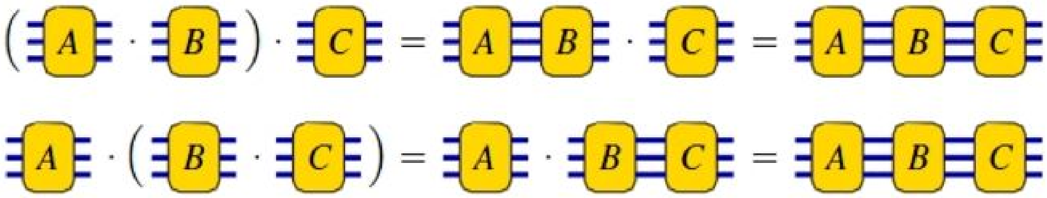

Figure 8.341: **Check of associativity of braids (by the multiplication)**

So the answer is YES regardless of the number of strands!

2. Is this representation commutative?:

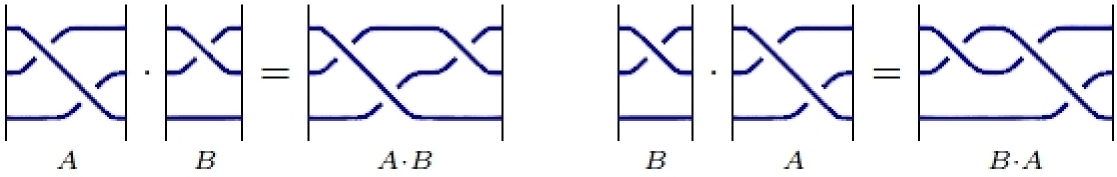

Figure 8.342: **Control of the commutativity of braids (by multiplication)**

The answer is therefore NO beyond 2 strands (because with 2 strands it is commutative)!

3. Does it admits a neutral element?:

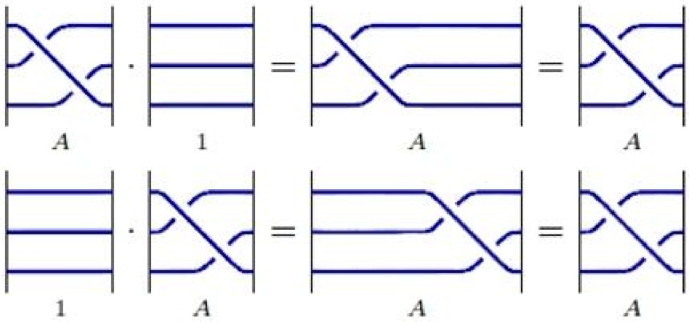

Figure 8.343: **Check of the existence of a neutral element for braids (by the multiplication)**

The answer is therefore YES whatever the number of strands!

4. Are there inverse elements (symmetrical)?:

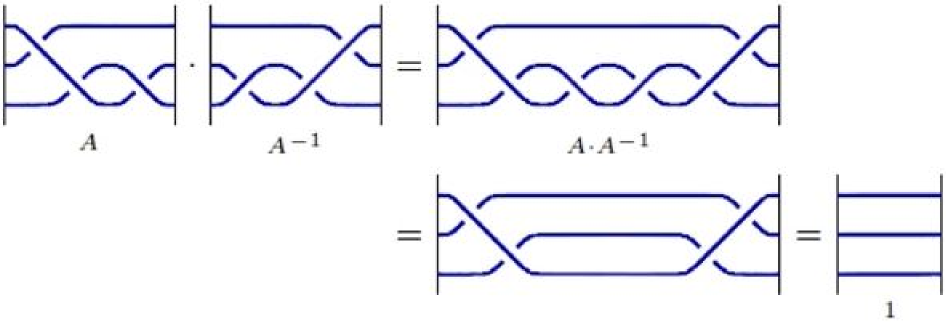

Figure 8.344: Check of the existence of an inverse element for braids (by the multiplication)

The answer is therefore YES whatever the number of strands!

Therefore the braids with n strands form a non-commutative group denoted by $(\mathcal{B}_n, \cdot)$ where the stylized B represent the word "braids".

Let us observe something interesting about the braids with two double strands. If we index their tendrils by integer numbers as below (imagine the braid from the middle of which you rotate the ends, it gives all other left and right tendrils):

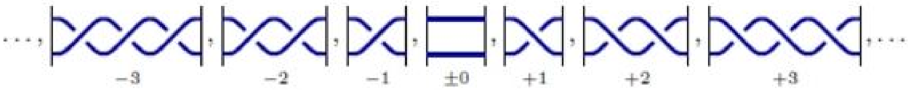

Figure 8.345: Indexing braids tendrils

with the convention of positive tendril v and negative tendril v:

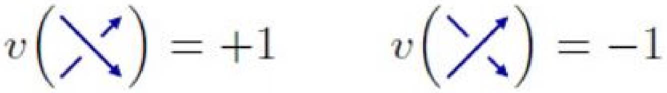

Figure 8.346: Indexation convention

Beware to the following trap! (try to find it ... it is not always easy at first glance):

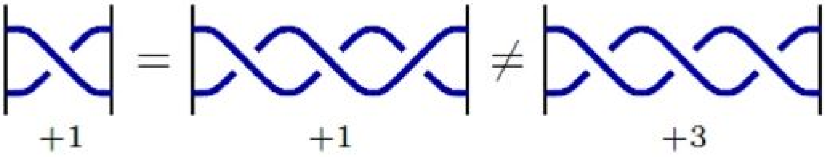

Figure 8.347: Indexation tendril trap

Indeed, the right crossing above of the second braid is precisely not .... a cross! Then we say that the number of crossing is not an invariant. It is for this reason that what matters is the "tendril" because it does not change in the movements of the braid at the opposite of a simply cross!!!

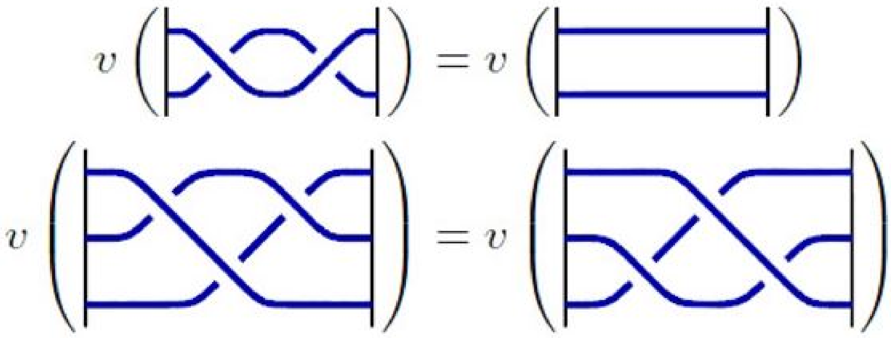

Figure 8.348: **Difference between tendril and cross**

We then notice that regarding to the multiplication of braids (see section Set Theory page 441) and their indexing under the form of their number of tindrels, we have the following properties:

$$f(A \cdot B) = f(A) + f(B) \quad \forall A, B \in \mathcal{B}_2 \qquad (8.9.2)$$
$$f(1_A) = 1_{\mathbb{Z}} \qquad (8.9.3)$$
$$f(A^{-1}) = (f(A))^{-1} \quad \forall A \in \mathcal{B}_2 \qquad (8.9.4)$$

So the multiplicative group of braid with 2 strands is a homomorphism of group with the addition law of the group of relative integers. Moreover, we see that the application f is trivially bijective. We have therefore a isomorphism of group! Beyond 3 strands, we saw that the group was not more commutative!

8.9.2 Knot Representation

Let us return to the first figure presented above:

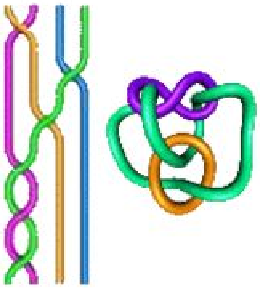

Figure 8.349: **Braid and corresponding string (node diagram)**

A first difficulty then appears for the image on the right (which is a "knot diagram"): a knot (a chain with a single strand) is a three-dimensional geometric object, and we are using a plane representation obtained by projecting the knot onto a plane. This could therefore complicate things... we will see!

Remark

Any node or any chain can be obtained from a braid (without proof).

There exists many possible views, and different appearances of the same node. Two nodes of different projections are distinct (not isotopes)? In the first published table of node classification (that of Tait and Little) the minimum number of crossings is used as a classification principle (up to ten crossings) and it took almost a century to detect one duplication (see table further below): two identical nodes were taken for different.

In practice a node rather looks like this:

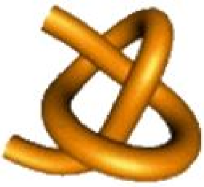

Figure 8.350: **Example of a node in real life**

But mathematicians have the usage to connect both ends of the string to get this representation of a node:

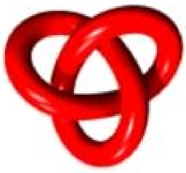

Figure 8.351: **Knot representation by mathematicians**

therefore a node is always a loop that closes on itself. In other words, an open node is always equivalent to a closed node:

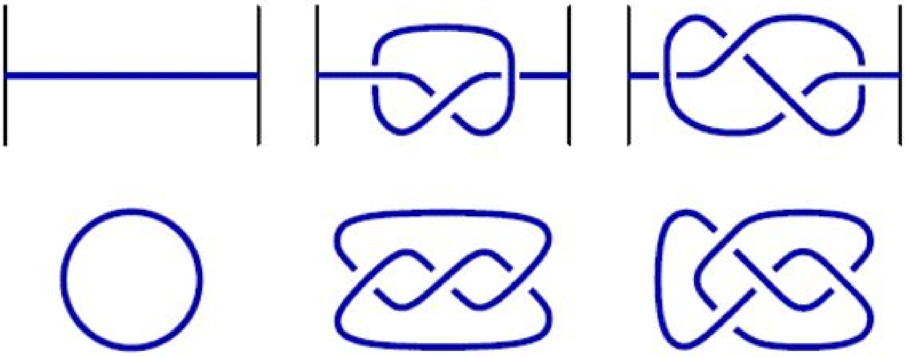

Figure 8.352: **Equivalence between an open and a closed knot**

A closed knot may look different depending on the angle from which we look at it. Thus, the two nodes below are two representations of the same type of knot named the "trefoil knot":

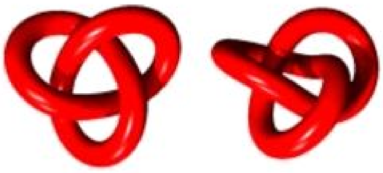

Figure 8.353: **2 different perspectives of the same trefoil knot**

Remark

The trefoil knot has a simple parametric equation given by:

$$\begin{aligned} x &= -\cos(t) + 2\cos(2t) \\ y &= \sin(t) + 2\sin(2t) \end{aligned} \tag{8.9.5}$$

That leads to:

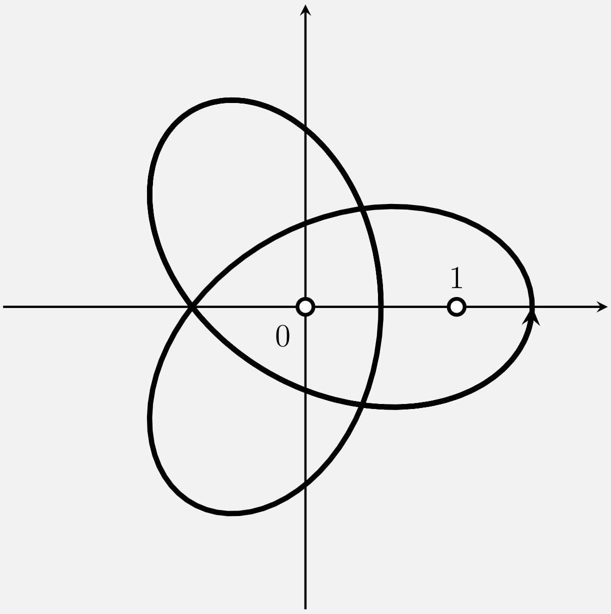

Figure 8.354: **Trefoil plot**

We can also ask ourselves if the left clover node and its mirror on the right are the same?:

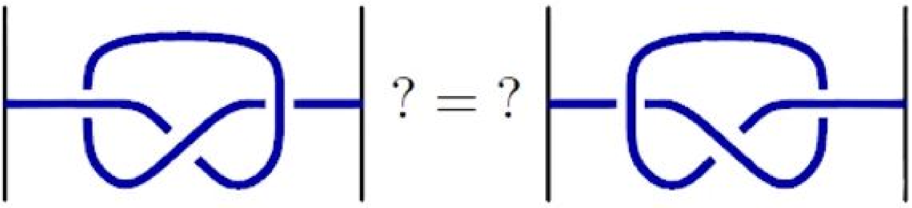

Figure 8.355: **Searching for equality between mirror symmetry of the clover node**

or the same question but when the two knots are closed:

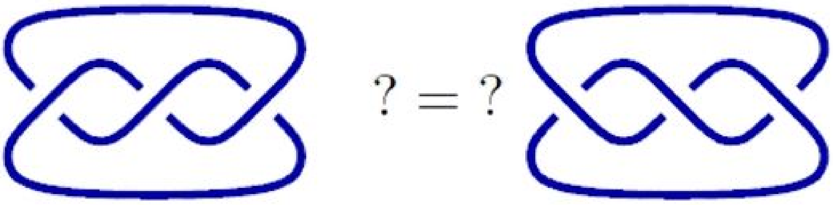

Figure 8.356: **Same situation but by closing the knot**

More difficult, K. A. Perko has showed that the two knots below, named "Perko pair", are in fact the same knot:

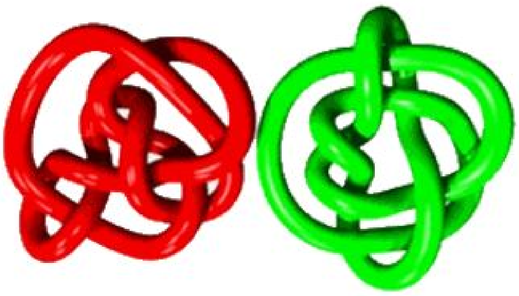

Figure 8.357: **Example of a Perko pair**

Another extreme (and funny) example are the Ochiai, Goeritz and Thistlethwaite knots below are in reality a simple unknot (!!!):

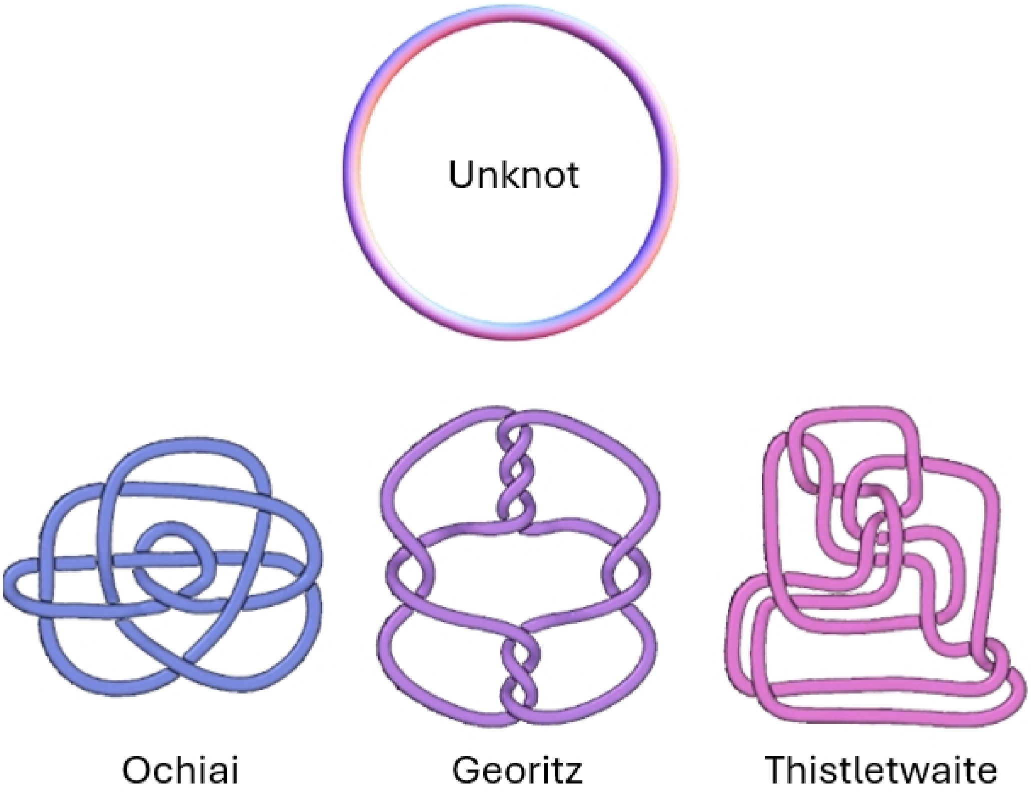

Figure 8.358: **Knots that are simply an unknot**

It is therefore not trivial to know two physical objects represents basically the same knot. But, that's what interests mathematicians! Specifically, they want to classify the knots, that is to say determining all types of nodes that are fundamentally different, and not just in appearance (it's the same idea than in topology where mathematicians successfully proved that every volume could be reduced to three primary volumes).

8.9.2.1 Knots Group

Just as we did for braids, let us look if knots form a group?

So we define the multiplication of two knots as the operation that is schematically:

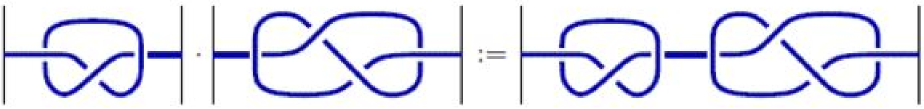

Figure 8.359: Refresh of the definition of the multiplication of two knots

We can ask ourselves if this is a commutative type group?

1. Let us start with the first check. Is this representation associative ?:

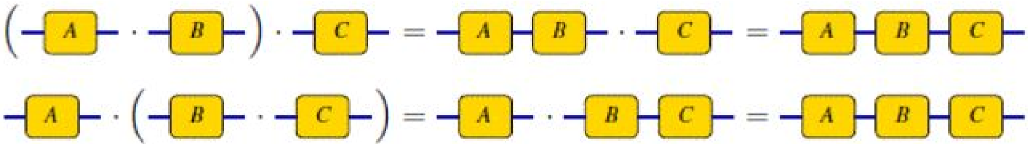

Figure 8.360: Check of the commutativity of knots (by the multiplication)

   The answer is YES whatever the number of knots!

2. Second control: does it have a neutral element?:

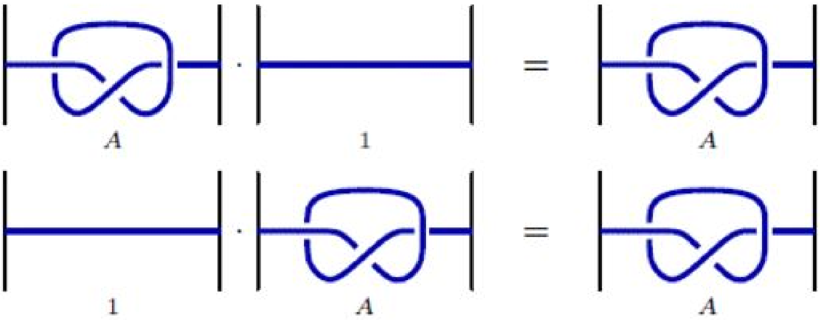

Figure 8.361: Check of the existence of a neutral element for the knots (by the multiplication)

   The answer is YES whatever the number of knots!

3. Third check: is it commutative?:

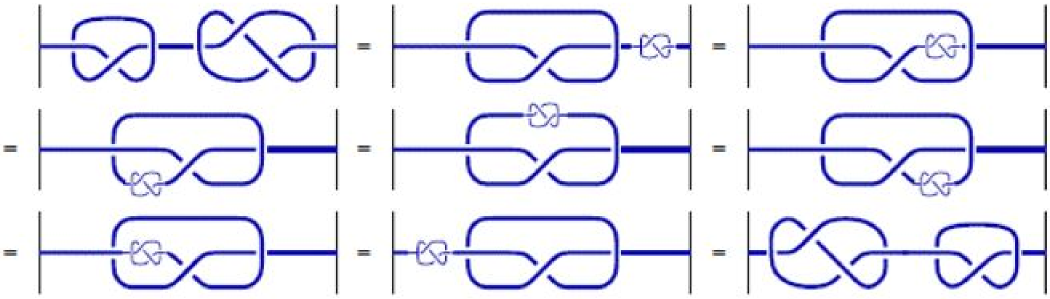

Figure 8.362: **Check of the commutativity of knots (by the multiplication)**

So unlike braids the answer is YES!

4. Fourth and last check: Are there inverse elements (symmetrical)?:

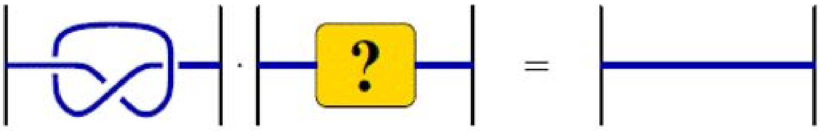

Figure 8.363: **Check of the existence of an inverse element for the knots (by the multiplication)**

and that's the one million dollar question!

With time and the efforts of mathematicians, three essential mathematical perspectives for studying knots emerged to solve different problems:

1. Topological, where the node is conceived as the union of a finite number of closed curves, define close to a given deformation.
2. Algebraic, where there count the intersections for example, and where we associate the groups to the nodes.
3. Geometrical, where we take into account the shape of the knot, measuring lengths or angles. In particular, the idea of the number of rotations appears as twisting and number of interlaces, and these concepts are fundamental to the study of DNA in molecular biology.

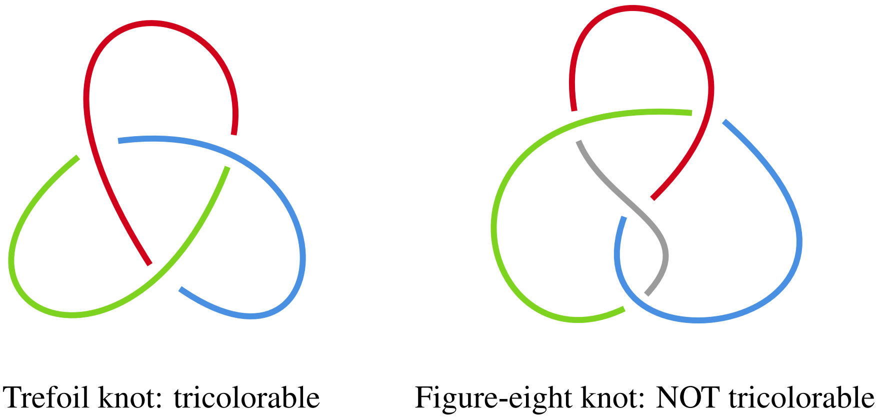
The link between these views is tricky. There are evidences hard to prove rigorously. We think especially to the Jordan theorem asserting that a closed flat curve without crossing defines an interior and an exterior! It took almost two centuries to properly define the concept of curve and there are wild knots to eliminate before any classification. We must take care to properly define the deformation of a knot, that mathematician named "isotopies".

The most effective mathematical idea for the study of the knots is probably that of "knot invariant". An invariant of a node is a characteristic (integer number, real number, polynomial, group, etc.) which remains unchanged during deformation. If we have/found an invariant, we can say that two knots are really different when the invariant does not take the same value for both knots. But if two knots have the same invariant, we can not say they are the same type (deformable into each other). A typical example of two knots having the same invariant and for which it is not trivial to say whether they are the isotopes are the right and the left trefoil knots when the chosen invariant is the number of crossings denoted by $c(D)$. We should for this purpose have a complete system of invariants.

Here, invariants are indispensable, and mathematicians have come up with dozens that distils different features of knots. But these invariants tend to have blind spots.

Take, for example, an invariant named "tricolorability". A knot diagram is tricolorable if there's a way to color its strands red, blue and green so that at every crossing, the three strands that meet are either all the same color or all different colors. Mathematicians have shown that even when you move the strands of a knot around, its tricolorability (or lack thereof) is unchanged. In other words, tricolorability is an innate feature of a knot.

The trefoil is tricolorable:



Trefoil knot: tricolorable
Figure-eight knot: NOT tricolorable

Figure 8.364: **Tricolorability of trefoil knot (source: Quanta Magazine)**

But the "unknot" (a loop that has no actual knots, even if it appears tangled) is not tricolorable, providing an instant proof that the trefoil is not just the unknot in disguise. But while tricolorability enables us to distinguish some knots from the unknot, it's not a perfect tool for this purpose: Knots that are tricolorable are definitely knotted, but knots that aren't tricolorable aren't definitely unknotted. For instance, the figure-eight knot is not tricolorable, but it is genuinely knotted. This knot falls into tricolorability's blind spot — it's as if the invariant is saying: "The figure-eight knot is unknotted as far as I can tell".

The "Conway knot", an ill-crossing knot discovered by John Horton Conway more than fifty years ago, is extraordinarily skilled at fooling knot invariants!

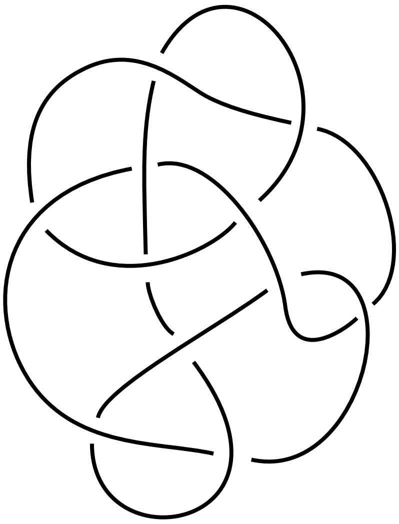


Figure 8.365: **Conway knot**

The Russian mathematician Victor Vasiliev introduced in 11990 (holocene calendar) a new class of invariants. It remains to make them explicitly computable and prove that they form a complete system.

Henri Poincaré introduced in 11900 (holocene calendar) the concept of fundamental group of a space which describes the possibilities of paths with return to starting point. Applied to the outer space to a node, this provides the "knot group" and the "Alexander polynomial" linked to it (see below the mathematical formalization).

The same construction applied to what is named the "configuration space" provides an effective definition of "braid groups". These groups were introduced in an intuitive form, circa 11920 (holocene calendar), by the Viennese mathematician Emil Artin, one of the fathers of modern algebra. Since 11937 (holocene calendar), the Russian mathematician Markov connected knots and braids, and gave a theoretical method to define, with braids, knots invariants.

At the beginning of years 11990 (holocene calendar), braid groups were a curiosity and their complexity repulsive. Then, suddenly, they have become a central theme of scientific research. Let us give an idea of the diversity of views that lead to braid groups:

1. In geometry, the Russian mathematician Vladimir Arnold classified under the name of "disasters" singularities of geometric configurations, which leads to the configuration spaces.
2. In algebra, specifically in group theory, two avatars of braid groups play a central role: the Coxeter's groups and the Hecke's algebras.
3. In statistical mechanics, the study of exactly soluble models is done through the use of Yang-Baxter relations and quantum groups. The link with the braid groups is profound.
4. The two-dimensional physics has recently taken great importance and we expect from it

a high temperature model of superconductivity. The usual classification of fermions and bosons particles is complicated in two dimensions. The new concept is that of anyone whose mathematical model is linked to braid groups.

5. Quantum field theory is the mathematical model of elementary particles. Edward Witten has made the bridge between this theory and braid groups, via the Jones polynomial.

The Knots Theory is therefore an active interface between physics and mathematics. Knots and braids now provide an effective modernization tool for the physic of polymers to the liquid crystal, through molecular biology. In the opposite direction, imported ideas of physics have sparked a revolution in mathematics: to somewhat marginal issue at the beginning of the years 11990 (holocene calendar), the Knots Theory at the beginning of the years 12000 (holocene calendar) one of the greatest mathematical subject.

8.9.3 Tait's Knot

The main aim of the knot theory is to clarify all knots and has its origin in physics in the early 119th century (holocene calendar) as we have already mentioned. Why?

Recall that at that time atoms were a mystery: why they seemed indestructible and why they exist in so many varieties and can be combined to give countless other components?

At that time the most beautiful equations of physics (which are often good candidates to explain things we do not understand...) were the Maxwell equations, then it was natural (or attempting) for physicists to try to explain the atomic mechanics in terms of electromagnetism, although we now know today that this path was destined to fail. Later in the mid 119th century (holocene calendar), electromagnetic waves were largely conceptualized as vibrations of a medium named at the time "phosphor ether". The repository of this ether was then defined (or at least suspected) as an absolute reference... But later, the experimenters Michelson and Morley (see [390]) showed that the relative motion of our planet in this ether was undetectable (and worse... they measured the absolute constancy of the speed of light as did De Sitter later with another type of experiment as described in his paper [133]!). Their experiences also led Albert Einstein and Henri Poincaré to develop their famous theory of Special Relativity (see section Special Relativity page 5627):

$$\vec{\nabla}\circ\vec{E}=0 \qquad \vec{\nabla}\times\vec{E}=\vec{0} \tag{8.9.6}$$

which is, we must admit, similar to fluid mechanics (see section of the same name page 3770) when we have an (assumed...) incompressible fluid without viscosity and without vortices:

$$\vec{\nabla}\circ\vec{v}=0 \qquad \vec{\nabla}\times\vec{v}=\vec{0} \tag{8.9.7}$$

More generally, if the rotational $\vec{\nabla}\times\vec{v}$ is not zero, Helmholtz proved in 11858 (holocene calendar) that the vortex field lines - defined by the lines of $\vec{\nabla}\times\vec{v}$ - move in the direction of $\vec{v}$ as if they had an independent existence (and here this is the open breach ... of course!). These lines could have no end but could form loops.

In 11867 (holocene calendar) the physicist Peter Guthrie Tait (assistant of Hamilton and a champion of quaternions) founded an ingenious way to prove this effect by cutting a circular hole in a box, filling it with smoke, and then expelling smoke afterwards through compression of the air in the box thereby forming smoke circles. It also showed this to his friend Kelvin that noted the analogy with electromagnetism and proposed a theory in which the atoms were vortex (knots) in ether! He hypothesized that the different types of atoms correspond to different types of knotted vortices (yes it's a bit farfetched but...)!

Tait subsequently tried to classify (see table below) tied lines in agreement with:

1. The number of interlaces when they are projected on a plane
2. By representing only the "main nodes"

Definition (#8.9.400): A node can be complicated because it is the succession of simple knots:

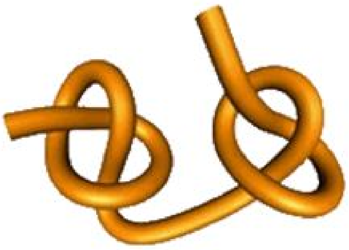

Figure 8.366: **Example of a succession of knots on an open knot**

These simple knots (with one strand) can be separated by cutting the string:

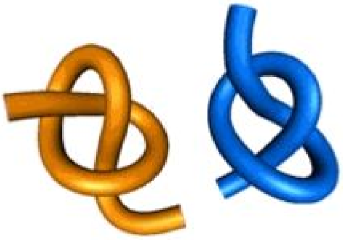

Figure 8.367: **Separation of the knot**

A main knot is a knot that can not be separated into simpler knots: cut the string unties the knot.

Classify knots this is trying to determine the building blocks: all main knots. The list Tait got initially was the following nodes (in the hope of obtaining the periodic table of elements but "ether" version...) and if necessary we recommend you to bring a string to ensure they are main one (sometimes it is mentally difficult):

Figure 8.368: Tait's classification

Remarks

R1. This table is very important and we will very often make reference to it for application examples using the proposed nomenclature.

R2. The corresponding values in the above table, named "knot complexity measures", are noted $c(D)_{\text{Id}}^{c(B)}$ in generality where $c(D)$ is the number of crossings, $c(B)$ the number of strands, and Id the number id of the node in the class $c(D)$.

The beauty of this model of "vortex atoms" was the fact that it was in agreement with the continuous appearance of the wonderful world of fluids, or to the Maxwell's equations by extension, to discretize the different types of atoms. A difficulty with this theory, however, was the remarkable stability of atoms. Kelvin admitted in 11905 (holocene calendar) after many years of failure in trying to prove that the movement Helmholtz circles was stable, the conclusion was that these circles were essentially unstable and should therefore dissipate. Curiously it is the extreme stability of the atoms that was one of the puzzle pieces to build the corpuscular quantum physics.

Moreover, with the theory of Special Relativity, the concept of ether that was precious to Maxwell and his contemporaries, especially regarding the Knots Theory, became synonymous of a useless concept and with the addition of the theoretical quantum theory vortex atoms was completely forgotten. Knot theory resurfaced because of some conjecture that Tait was not able to proved (we will come back about this later) that were proved only in the 11980s (holocene calendar) in a hazardous turn in theoretical physics.

What physicists abandoned intrigue mathematicians. The basic question remains the same: how can we say that two nodes are "isotopies" of each other (we will define further below what it is exactly). This question is closely related to the famous conjectures of Tait. To attack these conjectures and the basic problem of knots resemblance, the topologists developed invariants knots. An example of well known knot invariant and that have had a great success are the Alexander polynomial discovered by J. W. Alexander in 11927 according to holocene calendar (see further below). Thus, if the polynomials of two nodes are different, these are then not isotopies. Unfortunately, there are some knots having polynomials Alexander that are equivalents which are not isotopies of each other...

The mathematical knot theory then developed during fifty years was a bit forgotten until the thunderclap of Jones in 11984 (holocene calendar) of a new knot invariant (the Jones polynomial). The discovery of Jones is pretty exemplar of the scientific point of view and can lead to meditation on the current organization of science. Jones was not at all an expert on knots. He was interested in the classification of factors in von Neumann algebra (functional analysis). He obtained matrices algebras whose commutation relations (Yang-Baxter equations) were close relations of the braid group. From braids to knots, there is only one step that Jones has taken with the help of Joan Birman which is a specialist in knots.

Then we are see an explosion of discoveries: purely combinatorial version, new polynomial, etc. In 11989 (holocene calendar), Witten proved that the Jones polynomial can be obtained from quantum field theory by thanks to a Feynman integral, giving the first definition that does not use the flat projections of a knot. Somehow the Jones-Witten theory is a non-commutative extension of the work of Gauss. The Lie group (see section Set Algebra page 1417) which acts in magnetism is $\mathrm{U}(1)$, while the Witten invariant is a Feynman integral over a space of $\mathrm{SU}(2)$-connections.

8.9.4 Mathematical Formalisation

A node is mathematically modelled by an injective application, differentiable and whose derivative does not vanish, of the circle in oriented three-dimensional space (trivial knot).

The two central problems of the theory of knots is to decide in a calculable way if the knot is trivial (can be discard without cutting the string) or not (this problem is in this early 121st century (holocene calendar) not resolved as far as we know) and if two nodes are really equivalents.

The first type of problem can be well represented on the fact whether the knot below is knotted or not...?:

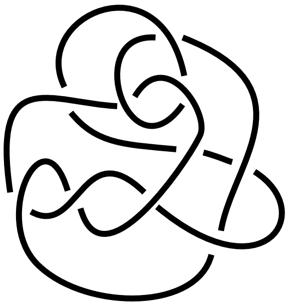

Figure 8.369: **Knotted knot?**

The answer is No! As shown in the figure below (read from left to right and top to bottom):

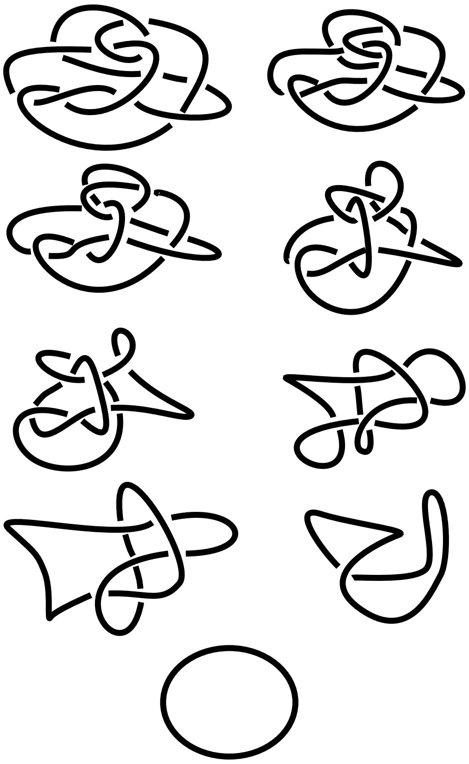

Figure 8.370: **It is not...!**

The goal for the second problem is to combine the knots computable mathematical objects (polynomials, numbers) named "knot invariants" and that are insensitive to the deformation of a knot. If the invariant is not equal to that the trivial knot that is:

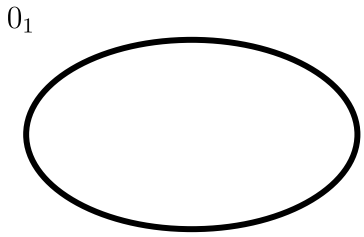

Figure 8.371: **Trivial Knot**

we are therefore sure that the knot is not trivial. And for example, the simplest non-trivial knot is the trefoil knot:

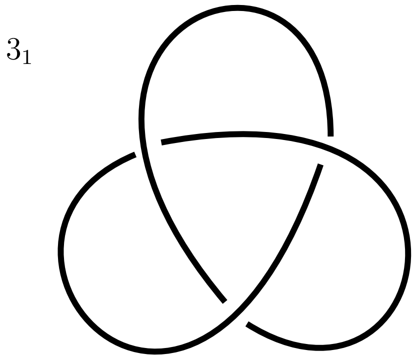

Figure 8.372: **Trefoil Knot**

The problem is finding enough fine tuning invariants. We will describe two of them:

1. The number of interlacing (of two knots), idea of Gauss, and which occurs in electromagnetism
2. The Jones polynomial (introduced in 11985 by Vaughan Jones, 11990 Fields Medal according to holocene calendar), which is subtle enough to distinguish for example right of the left trefoil knot.

We will also describe a general class of invariants: finite type invariants or Vassiliev invariants. These invariants defined in a rather unconstructive way are maybe complete invariants, but we do not know for sure at this beginning of the 121st century (holocene calendar). We will describe the number of interlacing of 2 knots as a combinatorial invariant calculable from a node diagram. We will then write the classical integral formula related to magnetism (Gauss) to calculate it. We will then do a little detour by the global differential geometry of curves in three-dimensional space to show the "White formula" that connects three geometric invariants associated with a ribbon. We will then describe the new polynomial invariant in a combinatorial point of view. The point of view of Feynman integrals will be discussed.

Victor Vasiliev has introduced a general family of invariants that contains most known invariants and we can say that they are of finite type. We will describe the principle.

In biology the RNA and DNA strand and also amino acid filaments are wound in complex three-dimensional shapes (these are closed braids, as we know a more general case of knots). However, often, through the microscope, we see only a two-dimensional projection. Invariants give the possibility to trace back to three-dimensional information from 2D views we have:

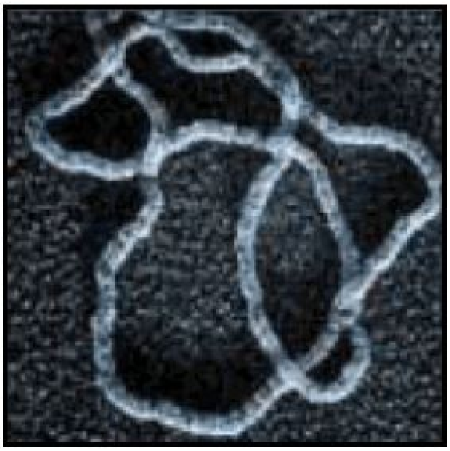

Figure 8.373: **Example of RNA or DNA strand**

On the other hand, biologists have observed knotted DNA molecules and found that the topological nature of the DNA molecule, that is to say the knot type formed by the molecule, affects its operational mechanism in the cells by conditioning some of its chemical properties. Some viruses attack cells by changing the long DNA molecules by interlacing them in different ways. Indeed, by the means of enzymes named topoisamérases, viruses cut and reattach different strands of the DNA molecule such that they take the form of a knot which can be very complex. It turns out that the type of knot obtained is in a way the virus signature. To fight effectively against the virus, it is imperative to recognize their signature by their action on DNA. Therefore to identify different viruses we must be able to recognize the different types of knots and this is where the theory of knots can help the biologist.

Remark

The identification of some knot type has been transformed by research centers in an online gaming which aims it to give a funny way to the people to contribute to find a solution. This seems to work since late 12011 (holocene calendar) some players seems to have made relevant discovery regarding the analysis of proteins.

Let us start now with some definitions. We have deliberately chosen to not to list a given number of definitions (as many in Graph Theory...) that the reader can easily find in literature or on the

Internet. We allow ourselves to omit them in the sense that they will not be helpful in the application of knot theory in quantum field physics (and except for those who like make small drawings... they are useless in our point of view).

Definitions (#8.9.401):

D1. A knot may be defined (as there are several possible definitions and some have small enough bothersome uncertainties...) by the image of the circle denoted by S^1 by a continuous application (the string is assumed as such), injective (this avoiding the string enters in itself):

$$f : S^1 \mapsto \mathbb{R}^3 \tag{8.9.8}$$

in other words, it is a curve without double points, drawn in Euclidean space of three dimensions.

A knot is therefore represented by an injective application $f \in \mathcal{C}^1([0,1],\mathbb{R}^3)$ (impose $\mathcal{C}^1$ class knots avoids having too wild curves ...) verifying that $f(0)=f(1)$ (closed knot). The image of f is sometimes named "support of the knot f": this is the "physical" realization of the knot in space.

Remark

All knots will subsequently denoted by the letter N.

To summarize crudely..., a knot is a string we for which we welded the ends.

D2. We say that a knot is a "trivial knot" if the application f that defines it extends in a continuous application of the disc $D^2 \mapsto \mathbb{R}^3$ and always injective: a trivial knot is therefore a knot that border an immersed disc of $\mathbb{R}^3$.

D3. Two knots γ_1,γ_2 are equivalent if there exists a continuous application:

$$F : [1,2] \mapsto N \tag{8.9.9}$$

such as $F(1)=\gamma_1$ and $F(2)=\gamma_2$. It remains to find F that is a curve in the set of curves.

D4. The $c(K)$ of a knot K is the natural integer representing the minimum number of crossings for every diagram of a knot type (that is a natural measure of complexity).

✍**Example:**

The knot 0_1 has a $c(K)=c(0_1)=0$ therefore null. It seems there exist no knots with $c(K)$ equal to the unit. A proof consist is to list all possible diagrams with one or two cross and see that they are in fact equivalent knots of the type 0_1 or just interlaces. The trefoil knot (knot 3_1) has a $c(K)=c(3_1)=3$.

D5. The mirror image $\bar{K}$ of a knot K is obtained by reflection on a plane in $\mathbb{R}^3$. The knot K can be constructed by inversion of crossing of the knot diagram:

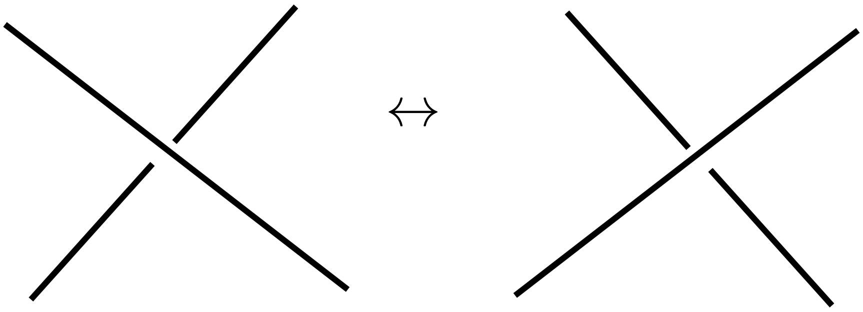

Figure 8.374: **Mirror image by crosses inversion**

✍**Example:**

With the trefoil knot ("left trefoil" and "right trefoil"):

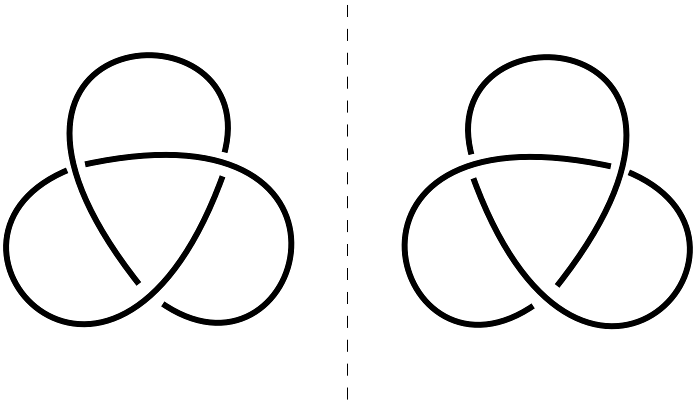

Figure 8.375: **Mirror of trefoil knot**

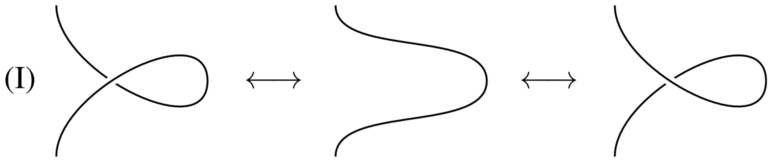
Remark

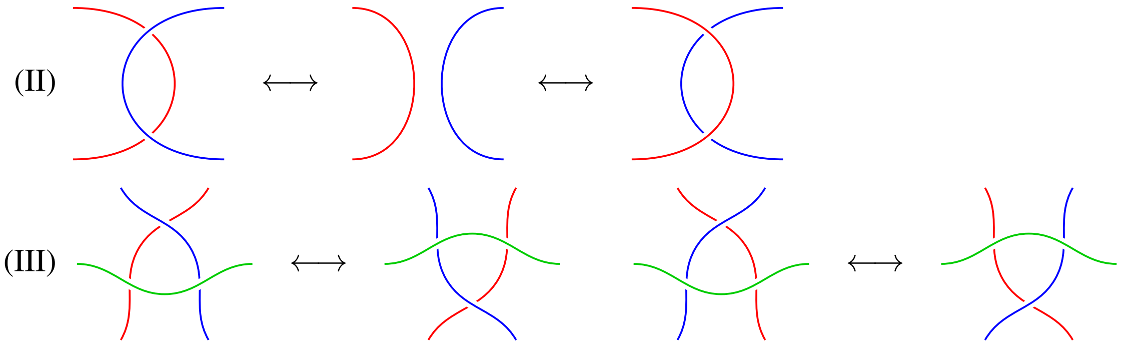
We also notice that in the Tait classification table, the mirrors knots are not represented!

D6. Two knots are say to be "isotopes knots" if we can switch from one to the other by continuous manipulation named "isotopies" (the left trefoil knot and right trefoil knot are for example not isotopes!) and as we know this is the problem number one in the knot theory: detect isotopes knots.

In other words, an isotopie is a movement which does not deforms/change the knot.

The isotopies give in the plane three particular types of movements named "Reidemeister movements":





It is therefore well three simple operations for changing a part of a knot without changing the nature of the knot itself.

So two diagrams or knots are isotopes, if we can pass from one to the other by a finite sequence of Reidemeister movements. Thus, with the example below, we show that the initial knot is equivalent to the trivial knot:

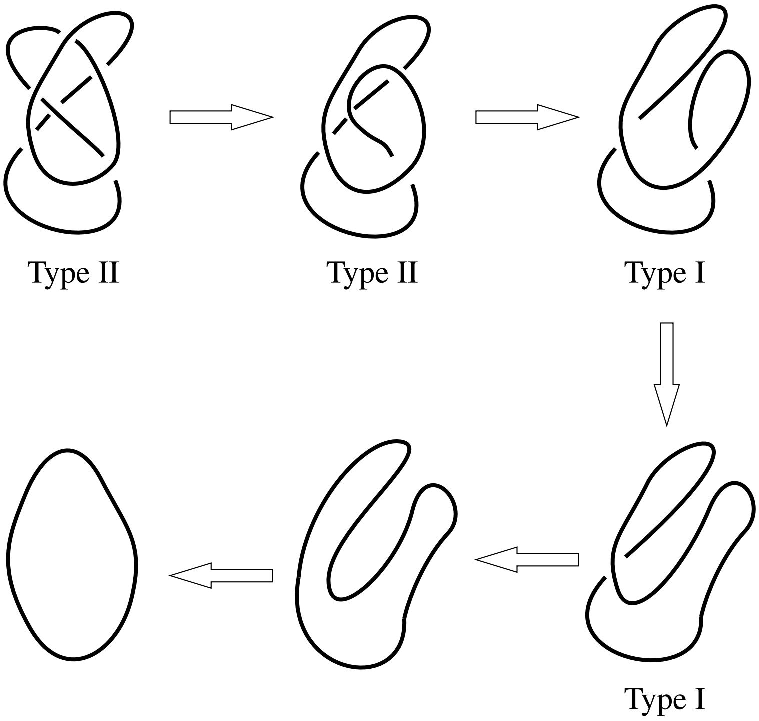


Figure 8.376: **Simplistic application example of the Reidemeister movements**

D7. Two knots are say to be "equivalent knot" or "amphicheiral". if they are isotopes OR if one is isotope to the image of the other in a mirror. According to the above definitions, each knot is necessarily equivalent to its own mirror image, but only reflective knots are isotopes to their mirror image. The eight knot 4_1 is a good example of this kind of knots, which are almost rare:

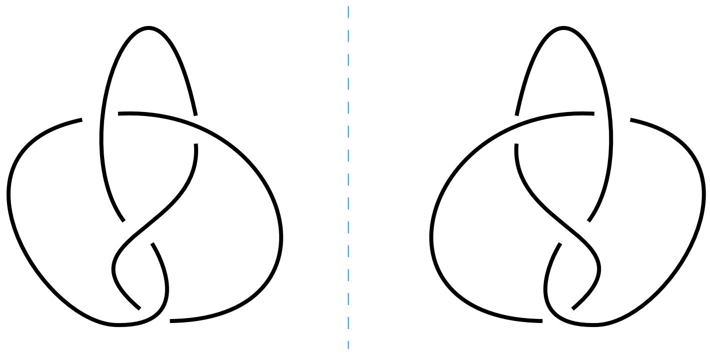

Figure 8.377: **Knot isotopie**

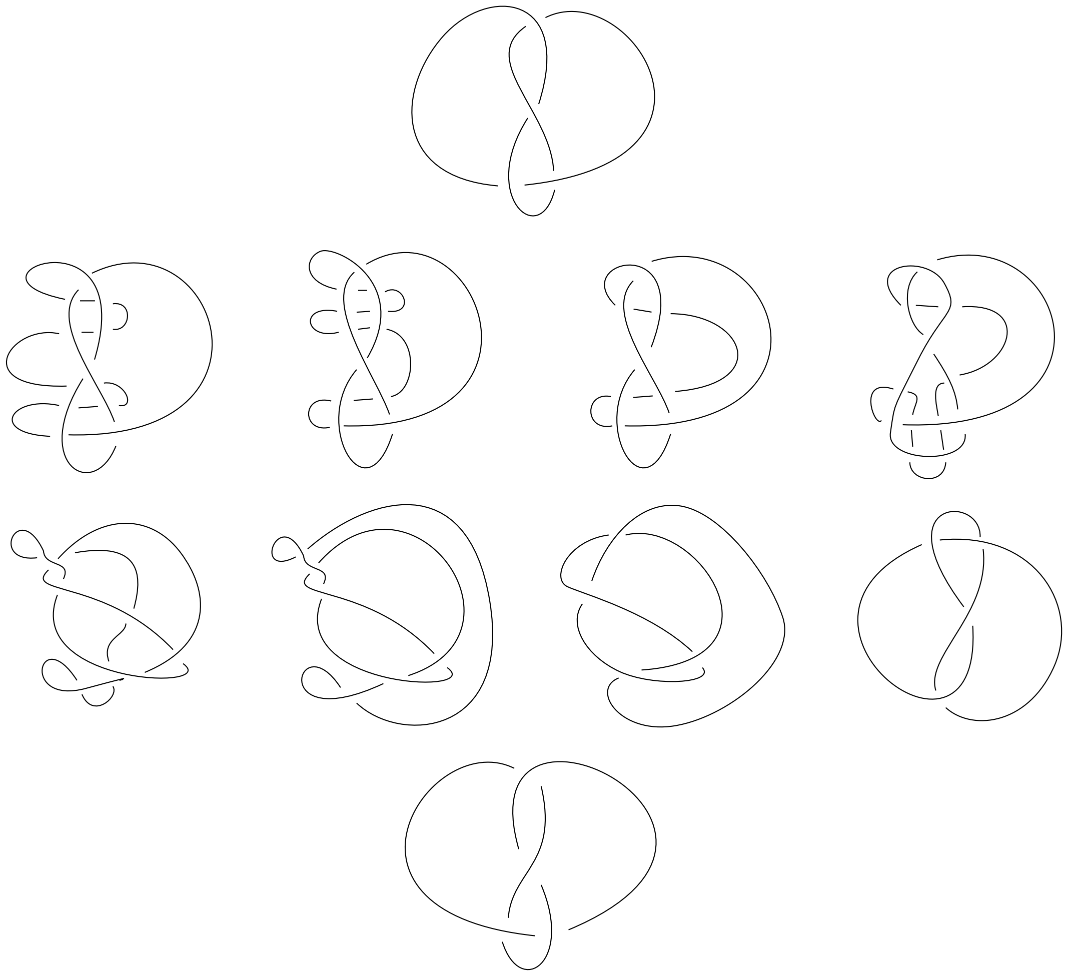
The corresponding Reidemeister movements are not always obvious to guess. Let us show you the details:



D8. An "interlaced" is a subvariety (see section Topology 2475) compact (see section Topology page 2447) of class $\mathcal{C}^{\infty}$ and of dimension 1.

D9. The "number of convex components" is denoted by $c(E)$. If $c(E)=1$ we say that E is a knot.

Most of time, interlaces are oriented (see section Graph Theory page 3012) and we will identify the isotopes interlacing. So we represent the interlacing in the plane by projecting and specifying the type of crossing points.

✍**Example:**

Interlaces with three convex components (left) and trefoil knot (right):

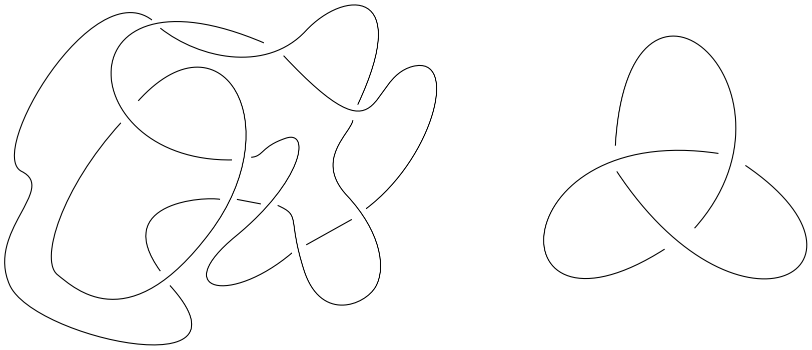


Figure 8.378: **Interlaces with three convex components**

For sure two interlaces are isotopes if and only if we can move from one to the other by a finite sequence of Reidemeister movements.

D10. Three interlaces E_+,E_-,E_0 are named "associates interlaces" if they differ only in a crossing point and that at this point they are in one of the following configurations:

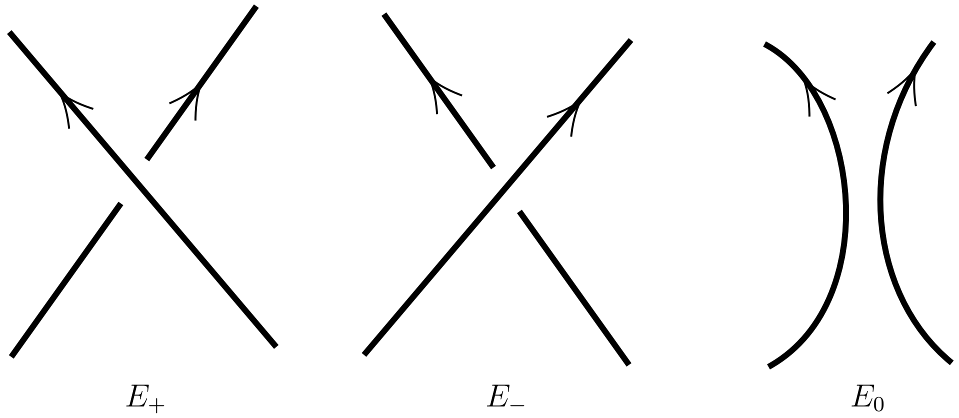

Figure 8.379: **Example of associated interlaces**

We denote by $\mathcal{E}$ the set of all interlacing classes and we will now focus in functions of the type $P:\mathcal{E}\rightarrow A$ where A is a commutative ring (the reader will must forget that we have seen that the coefficients of a polynomial are elements of a ring).

Remark

We must also remember that a knot is a curve and that any curve can be represented by a polynomial, hence the idea...!

D11. P is say to be "invariant by association" (by association interlaces...) if:

$$P(\bigcirc)=1 \tag{8.9.10}$$

and if there exist invertible $a_+,a_-,a_0\in A$ such that for any associated interlacing triplet (E_+,E_-,E_0) we have (!):

$$a_+P(E_+)+a_-P(E_-)+a_0P(E_0)=0 \tag{8.9.11}$$

We can already prove in a fairly basic way that if such a polynomial exists, then it is uniquely determined by the coefficients of the above equality. We summarize this in the following theorem:

Theorem 8.32. If P is invariant by association, then it is uniquely determined by the coefficients a_+,a_-,a_0.

Proof 8.32.1. Let us notice first that:

$$\forall r\in\mathbb{N}\qquad P(\bigcirc^r)=\left(-\frac{a_+a_-}{a_0}\right)^{r-1} \tag{8.9.12}$$

where $\bigcirc^r$ describes the knot consisting of r non-interlaced circles. Indeed, the relation $P(\bigcirc)=1$ and the invariance property of P applied to the following interlaces:

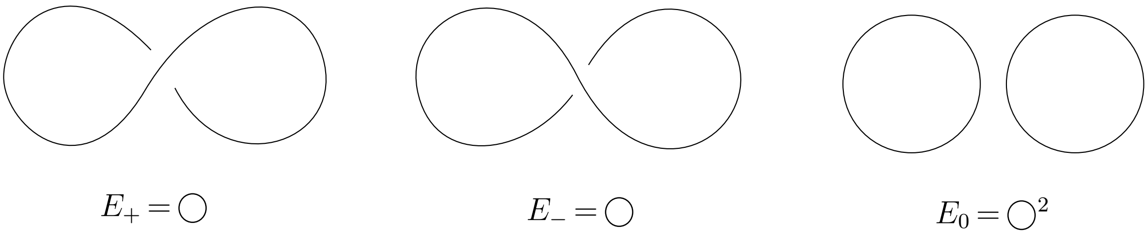

Figure 8.380: **Example of non-interlaces notation**

gives:

$$a_+P(\bigcirc)+a_-P(\bigcirc)+a_0P(\bigcirc^2)=0 \tag{8.9.13}$$

Therefore we get:

$$P(\bigcirc^2)=-\frac{a_+P(\bigcirc)+a_-P(\bigcirc)}{a_0}=-\frac{a_+\cdot 1+a_-\cdot 1}{a_0}=\left(-\frac{a_+a_-}{a_0}\right)^{2-1} \tag{8.9.14}$$

Thus, by induction on r we get:

$$P(\bigcirc^r)=\left(-\frac{a_+a_-}{a_0}\right)^{r-1} \tag{8.9.15}$$

■ Q.E.D.

In other words, the function P can be expressed only by its coefficients!!! So we can now try to see if a knot full of interlaces may always be reduced to $P(\bigcirc)$ recursively.

8.9.4.1 Planar Representation

We assume that the knot is in the oriented three dimensional Euclidean space. We look at projections of a knot on the plane $z = 0$. It is intuitively clear that we can assume that node has no vertical tangent and that the crossing points are only double and transversal. Such screening will be named a "good projection".

We then indicate at each crossing point which is the strand which passes over the other. Such a drawing represents a knit in a non-unambiguous way: we say that we have a "knot graph". Of course, two equivalent knots have good projections that give different knots diagrams in general (herein lies also one of the problems as well). It is therefore important to read the equivalence of two knots directly on their charts.

Here is an example with the trefoil knot:

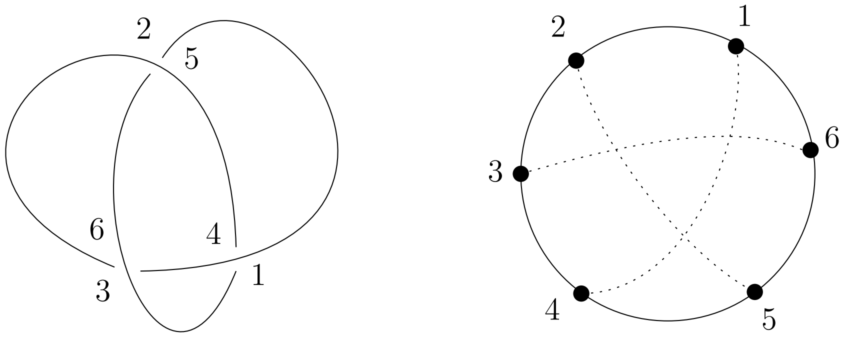

Figure 8.381: **Trefoil knot and its diagram**

> **Remark**
>
> The trefoil knot is the knot having the minimum number of intersections, namely 3; it actually exists in two amphiceiral (images of one another by reflection for refresh...). This is in fact in a simple knot the ends have been welded. The trefoil knot is the border of a Möbius with three half-twists and also the torus knot of order $(3,2)$ (3 windings around the core, on two revolutions), as well as the on of order $(2,3)$.

As a drawing is not necessarily easy to transmit, or to draw on a computer, we can also give a coding diagram of the knot by a matrix with integer coefficients at three lines and whose number of columns equals the number of double points.

We number the $2n$ crossing points on the closed curve (circle) in the order they arrive. We note that the pairs are all formed of an even number and an odd number. We build then the first two rows of the matrix by putting in each column both numbers giving the same projection: the odd on the first row, the odds on the second one. We then add to each column, an ± 1 indicating the orientation of the two strands (oriented) ($+1$ if the bottom one passes through from right to left when we traverse the top one, -1 otherwise). For example, the matrix associated with the trefoil knot of the previous figure is:

$$3_1=\begin{bmatrix}1 & 3 & 5\\ 4 & 6 & 2\\ + & + & +\end{bmatrix} \tag{8.9.16}$$

9.1. Principia

BY introducing the Mechanics through the Principia of Physics we finally do, after a veeeery long and necessary travel into the beautiful world of mathematics, our first steps in the field of theoretical physics (in a simplified version) who does not seek only the precision but also most of times the understanding of phenomena (exact numerical simulations and calculations and real life experiments give anyway very similar results of the theories as we will see). Understanding a theory in physics is primarily equivalent understanding the underlying mathematics behind. The rest is just some imagination and if possible, observation.

As we have already said, physics is a fundamental science that has a profound influence on all other sciences and also on human society and that aims to explain the *how*, not the *why* (see the Introduction of this textbook for details). Future physicists and engineers are thus not the only ones who should have understood its basic ideas, but anyone considering a career in science (including students majoring in biology, chemistry, mathematics and finance) should acquire the same comprehension.

quote
9.1:3068.#60

> *All science is either physics or stamp collecting!*
>
> Ernest Rutherford

The primary purpose of this textbook, we insist..., is to give the reader a unified view of physics by presenting what we think are the fundamental ideas that constitute the body of knowledge (absolute minimum) of contemporary physics.

Often, physics is taught as if it were a juxtaposition of several sciences, more or less connected, but without any real concern for unity and detail (which is why the majority of books and websites are without proofs). We rejected this mode of teaching (to have suffered of this during our studies) and opted for a unified and carefully detailed presentation by making when necessary reference to a section of the books that contains the proofs of mathematical tools used or another underlying physical theory. Obviously the law, relations and equations of physics can be compared to a computer program that possess, in addition to their immediate logical sense, most of time incomplete, a more global sense that can be revealed only sequentially according to the progress of mathematics and of our understanding of our Universe.

We also insist that every reader should know the basics of logic, arithmetic, algebra, vector calculus, linear algebra, tensor calculus, differential and integral calculus and analytical geometry prior to the study of physical phenomena to work with all rigour and all the necessary understanding to the mathematical reasoning that will be introduced from now (mathematics is the foundation of the huge edifice of theoretical physics!). We will see in what follows that all tools or mathematical results presented so far will be used !!

Let us recall that "Theoretical Physics" is the "exact/deductive science" that takes care of the best mathematical modelling natural phenomena, artificial, observable or non-observable. In shorter terms, we could talk about description of "reality" as to know if it is sensible or true reality...

When we want to predict or describe a specific physical phenomenon, we can usually go through an analytical model where different values given by unspecified (abstract values: variables) and the laws of physics by functions, when they are known (if so, we can make a hypothesis and test it). By equating a physical phenomenon, we translate reality (measurements) into a mathematical experience, virtual, according to certain rules. We conduct a simulation of reality on expressed quantities.

The different "laws" are often historically developed on empirical facts first and are subsequently verified experimentally (see the hypothetical-deductive method in the section of Proof Theory at page 141). Assuming that these laws are valid in the context (time frame, basis frame, etc.), we can therefore expect that the mathematics are in line with the experimental facts (or vice versa). Of course, a virtual experience is not real and can not express the reality in all its subtlety. This is only a model! It is therefore clear that the prediction of a physical phenomenon may differ from actual experimental facts.

Remarks

R1. We would like to recall (because of an abuse or misunderstanding that we find too often on various Internet forums), that a "scientific experiment" is a practical work of the study of a phenomenon which is reproducible (by independent research groups) in similar conditions and which number of reproductions is high enough to ensure that the errors (standard deviations) on measures become negligible between the independent groups (there are also international ISO norms for this purpose!!!).

R2. It should also be noted that most theoretical models that we will study now in this textbook making use of algebra or vector analysis and can be rewritten with the tools tensor analysis and based on the methods of Lagrangian formalism (see section Analytical/Lagrangian Mechanics page 3155 for know what it is...). However, these latter methods can not easily be used for a simple introduction to physics because they require additional efforts from reader and much more paper and time to get the same results (often at least...). However, and we will come back about this, these methods are now essential and of primary importance in the various fields of high-level modern physics such as Fluid Mechanics, General Relativity, Quantum Field Physics, analysis of chaotic systems and some others.

Before we begin our study of physical phenomena, we must define the main concepts on which theoretical physics is based. Thus, we will see in the order:

1. Human beings have created a system of measurement units which are arbitrary standard quantities to a given coefficient (this is why still some countries in the world don't have the same methods to count time or to weight objects even if there are ISO norms), specific to identify simply and in a reproducible way every physical phenomenon.
2. Some concepts interrelated to our vision of our environment lead us to make Assumptions/Hypothesis and Principles (to postulate something...) which relate to our sensory

reality while being transposed to any other reality of this type.

3. Theoretical physics leads us to consider the fundamentals of nature as abstract mathematical concepts. Thus our common observation gives us a concrete view of the Universe while theoretical physics gives us an abstract view of it. But theoretical physics let us sometimes inspects and understand (at least we suppose it) phenomenons that cannot be observed experimentally (or some dozens or hundreds years later only after technologies developments).

Then we can be led to ask however the following question: do the facts determine which theory/model is true?

By observing nature, we can see facts: this is data that we do not create. Astronomers, for example, note the position of celestial objects. We understand a fact since it appears as the consequence of the order of things described by a theory. But theories still retain the status of assumptions: even when a theory is consistent with all observed facts, it does not prove it to be true (a famous example is the Theory of Evolution considered by many people as being absolutely true even if it does not respect the scientific protocol). Indeed, there is still an infinite number of possible theories that are all compatible with all the observed facts. Then we say that the facts "sub-determine" theories: facts impose constraints on theories in the sense that only the theories consistent with the observed facts, are acceptable. But these constraints will always be low enough to leave the choice among an infinite number of theories.

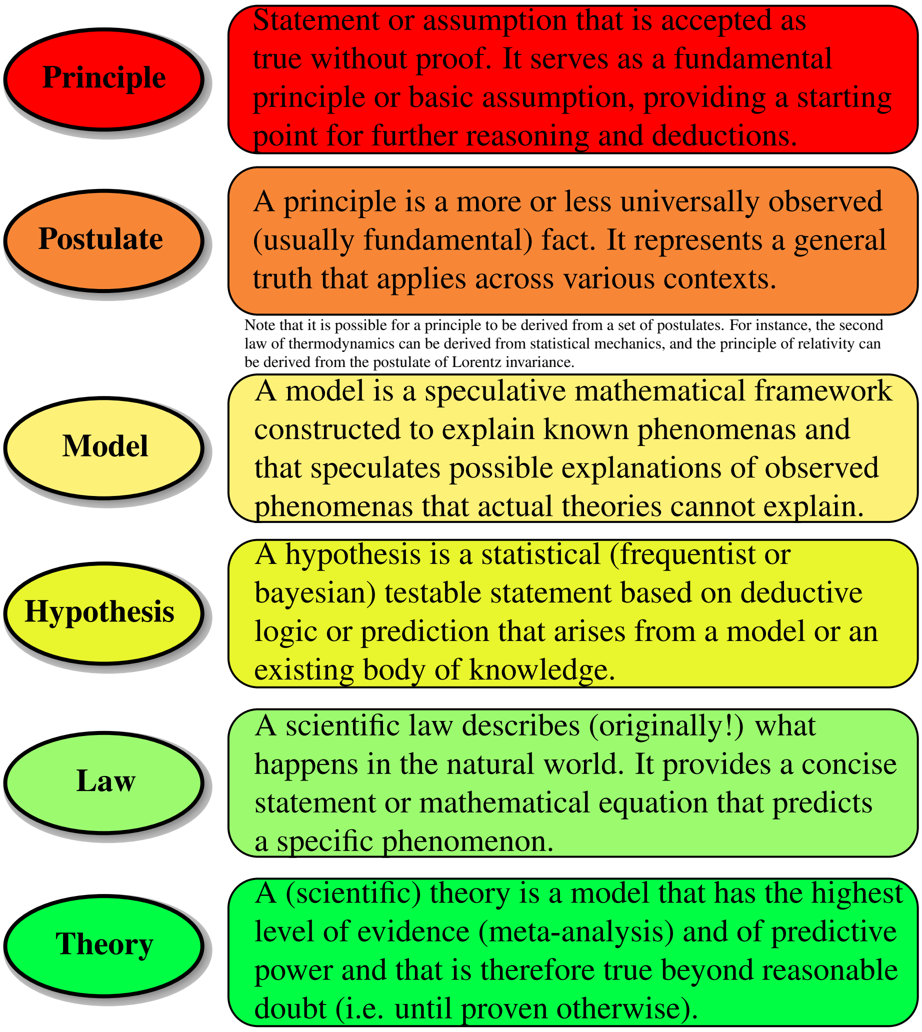
Theoretical advances may consist in setting aside old, incorrect paradigms (e.g., aether theory of light propagation, caloric theory of heat, burning consisting of evolving phlogiston, or astronomical bodies revolving around the Earth) or may be an alternative model that provides answers that are more accurate or that can be more widely applied.

Theoretical physics consists of several different approaches. In this regard, theoretical particle physics forms a good example. For instance: "phenomenologists" might employ (semi-) empirical formulas to agree with experimental results, often without deep physical understanding. "Modelers" (also named "model-builders") often appear much like phenomenologists, but try to model speculative theories that have certain desirable features (rather than on experimental data), or apply the techniques of mathematical modelling to physics problems. Some attempt to create approximate theories, named "effective theories", because fully developed theories may be regarded as unsolvable or too complicated. Other theorists may try to unify, formalise, reinterpret or generalise extant theories, or create completely new ones altogether. Sometimes the vision provided by pure mathematical systems can provide clues to how a physical system might be modelled. Theoretical problems that need computational investigation are often the concern of computational physics.

Of course, scientists are actually considering a finite number of theories, depending on what seems easiest in a given conceptual framework. At the time of Kepler, for example, there were three main theories to explain the movements of the planets, all consistent with the observed facts. According to the Ptolemaic theory, planets orbits are circular or located on a epicycle around the Earth motionless at the center of the universe. In the Copernican theory[1], the Sun (actually a G2V-type star, aka yellow dwarf) occupies the center, the orbits of the planets and the Earth being located on circles and epicycles. In the Keplerian theory, planets orbits are ellipses with the Sun at one focus and finally comes General Relativity that we will study later... (see page 5720).

---

[1] In reality the first one to make the assumption of heliocentric system seems to be the greek Aristarchus of Samos almost 1600 years before Copernicus (see [563])!



Principle

Statement or assumption that is accepted as true without proof. It serves as a fundamental principle or basic assumption, providing a starting point for further reasoning and deductions.

Postulate

A principle is a more or less universally observed (usually fundamental) fact. It represents a general truth that applies across various contexts.

Note that it is possible for a principle to be derived from a set of postulates. For instance, the second law of thermodynamics can be derived from statistical mechanics, and the principle of relativity can be derived from the postulate of Lorentz invariance.

Model

A model is a speculative mathematical framework constructed to explain known phenomenas and that speculates possible explanations of observed phenomenas that actual theories cannot explain.

Hypothesis

A hypothesis is a statistical (frequentist or bayesian) testable statement based on deductive logic or prediction that arises from a model or an existing body of knowledge.

Law

A scientific law describes (originally!) what happens in the natural world. It provides a concise statement or mathematical equation that predicts a specific phenomenon.

Theory

A (scientific) theory is a model that has the highest level of evidence (meta-analysis) and of predictive power and that is therefore true beyond reasonable doubt (i.e. until proven otherwise).

Figure 9.1: **Reminder of hierarchies of concepts in modern experimental science**

9.1.1 System of Units

The range of objects and phenomena studied in physics is immense. From the incredibly short lifetime of an atomic nucleus to the age of Earth, from the tiny sizes of sub-nuclear particles to the vast distance to the edges of the known universe, from the force exerted by a jumping flea to the force between Earth and the Sun, there are enough factors of 10 to challenge the imagination of even the most experienced scientist. Giving numerical values for physical quantities and equations for physical principles allows us to understand nature much more deeply than qualitative descriptions alone. To comprehend these vast ranges, we must also have accepted units in which to express them. We shall find that even in the potentially mundane discussion of meters, kilograms, and seconds, a profound simplicity of nature appears: all physical quantities can be expressed as combinations of only a few base physical quantities.

Definition (#9.1.402): A "measurement" or "physical quantity" is the quantitative nomological expression of a property, of an effect or an abstract quantity defined by a model that represent the object or phenomenon under study. A fundamental measurement does not explain itself, it described itself with respect to a definition.

Definition (#9.1.403): A "unit of measurement" is a definite magnitude of a physical quantity, defined and adopted by convention or by law, that is used as a standard for measurement of the same physical quantity. Any other value of the physical quantity can be expressed as a simple multiple of the unit of measurement.

In fact it's not enough to simply agree on units of measurement! These have to be consistent, reliable and standardized in order to enable international collaboration and interoperability. There is a science to measurement, and it's named "metrology".

✍**Example:**

For example, length is a physical quantity. The "meter" is a unit of length that represents a definite predetermined length. When we say 10 meters (or 10 [m]), we actually mean 10 times the definite predetermined length named "meter".

We recognize two types of measurements:

1. The "constants": they have a concrete value expressible numerically and are supposed not to change during the studied phenomenon. They are "passive measurements" (we come back later on this and will enumerate some of them).
2. The "variables": they have a concrete value only in a particular state, but not when we observe the physical phenomenon as a whole (during all a range of time). These are "active variables". The variables describing a physical phenomenon are often correlated to each other by means of functions. Then by definition we say that these variables have a "functional relation" between them.

Remark

One measurement only makes sense if it is "observable", measurement to which we associate a number, the result of the measurement performed by using a device.

Measure a physical quantity is equivalent to compare it to a known quantity of the same kind (we also say "of the same dimension"), taken as an arbitrary standard (the rigorous approach of this related the abstract modern Measurement Theory that we have already study in the section of the same name). The measurement result is expressed thanks to two elements:

1. A number which is the ratio of the measured quantity to the standard of the measurement quantity.
2. A name or acronym that identifies clearly the chosen standard.

The notation of a measurement A is therefore in abstract form:

$$A=\{A\}\,[A]=n\{S_A\}\,[\mathrm{A}] \tag{9.1.1}$$

The "number" $\{A\}$ is in fact the measured value (magnitude) of the quantity A as multiple n of the corresponding standardized unit $\{S_A\}$ and $[A]$ is its "name" that we commonly name "physical unit" or simply "unit" (the quantitative expression of a variable or a function). These two elements are inseparable, the measured value is meaningful only if we show the same time the selected unit. It changes if we change the unit!!!

Remark

The transition from one unit to another to express the same quantity is named "unit conversion". Conversion of units involves obviously the comparison of different standard physical values, either of a single physical quantity or of a physical quantity and a combination of other physical quantities.

Starting with:

$$A=n\{S_A\}\,[\mathrm{A}]$$

just replace the original standard reference unit $\{S_A\}$ with its meaning in terms of the desired unit $\{S_B\}$, if:

$$\{S_A\}=c_{A\to B}\,\{S_B\}$$

then:

$$A=n\{S_A\}\,[\mathrm{A}]=nc_{A\to B}\{S_A\}\,[\mathrm{B}]=n\{S_B\}\,[\mathrm{B}]$$

Now n and $c_{A\to B}$ are just the numerical values corresponding respectively to the multiplicand of the standard and the conversion factor, we just have to multiply them to finish the job.

✍**Examples:**

E1. One example of the importance of agreed units is the failure of the NASA Mars Climate Orbiter, which was accidentally destroyed on a mission to Mars in September 11999 (holocene calendar) instead of entering orbit due to miscommunications about the value of forces: different computer programs used different units of measurement (newton versus pound force). Considerable amounts of effort, time, and money were wasted.

E2. On 15 April 11999 (holocene calendar), Korean Air cargo flight 6316 from Shanghai to Seoul was lost due to the crew confusing tower instructions (in meters) and altimeter readings (in feet). Three crew and five people on the ground were killed. Thirty-seven were injured.

E3. In 11983 (holocene calendar), a Boeing 767 ran out of fuel in mid-flight because of two mistakes in figuring the fuel supply of Air Canada's first aircraft to use metric measurements. This accident was the result of both confusion due to the simultaneous use of metric and Imperial measures and confusion of mass and volume measures.

Definition (#9.1.404): Some variables can, for the sake of simplification of writing, be expressed from other quantities. We then say that the new quantity "derives" from base units. We also say that two physical quantities are "homogeneous quantities", or "dimensionally consistent", if they are of the same physical nature or if we can express them both in the same basis unit(s).

This also means that the equations in physics must obey the following rules:

- Every term in an expression that is added or subtracted must have the same dimensions; it does not make sense to add or subtract quantities of differing dimension. In particular, the expressions on each side of the equality in an equation must have the same dimensions.
- The arguments of any of the standard mathematical functions such as trigonometric functions (such as sine and cosine), logarithms, or exponential functions that appear in the equation must be dimensionless. These functions require pure numbers as inputs and give pure numbers as outputs.

So, after a long period of reflection the physical world seems to be reducible to the concepts of space, time and energy.

Thus appears another possible definition of Physics:

Definition (#9.1.405): "Physics" is the science of the properties and mutual relations in time of matter and energy to a given factor.

Our role is to give a description of these properties and relations under the form of physical equations or laws applied to observed phenomena in the context of a theory providing predictable facts.

Physical quantities are not all independent of each other but linked by certain laws or relations. It would be unreasonable, but possible, to choose a particular unit for each of the physical quantities regardless of their mutual relations.

Build a coherent system of units consists therefore to determine a minimum number of units that establish the rules of construction of these mutual relations. Indeed, historically, a lot of units has been set for the measurement of a single quantity to meet specific needs of areas of practical life or science and technology. Their choices and their definitions were often empirical (or even based on religious beliefs sometimes!), and hence the conversions between units not always easy or clear.

Figure 9.2: **Based ISQ units and derived units**

In regards to the evolution of sciences and technologies, at the increased exchange of information, the need to unify the system appeared obvious, the aim being to keep a small as possible number of units. These are the "fundamental units". From the physical laws and relations between the different fundamental units, we deduce the units of other values which then become then by sake of simplification of writing "derived units".

The choice and definition of the fundamental units set is a complex issue. Indeed, these units must be highly accurate and available in measurement laboratories of the entire planet.

Remark

The International System of Quantities (ISQ) is a system based on seven base quantities: length, mass, time, electric current, thermodynamic temperature (see definition at page 3935), amount of substance, and luminous intensity. Other quantities such as area, pressure, and electrical resistance are derived from these base quantities by clear non-contradictory equations. The ISQ defines the quantities that are measured with the SI units. The ISQ is defined in the international standard ISO/IEC 80000, and was finalized in 12009 (holocene calendar) with the publication of ISO 80000-1 *Quantities and units*. A small summary is given the figure above.

The basic units are at the number of 4 (we will justify this later): the length (meters), mass (kg), time (seconds), the electric charge (coulombs). This system then constitutes the "M.K.S.C. system" (the main redactor of this textbook assumes the choice of adding the Coulomb as fundamental unit).

The units of the M.K.S.C system are within this textbook (according to the early 121st century standards in most countries around planet Earth):

1. The meter [m], for the length L (we have already defined the concept of length in the chapter Geometry but we will come back again on it later). Since 12018 (holocene calendar) it is defined by taking the fixed numerical value of the speed of light in vacuum (as we will see during our study of Quantum Field Theory, vacuum isn't really empty) c to be $299,792,458$ when expressed in the unit $\mathrm{m}\cdot\mathrm{s}^{-1}$, where the second [s] is defined in terms of the caesium frequency $\Delta\nu_{\mathrm{Cs}}$. Hence:

$$1\;[\mathrm{m}]=\frac{c}{299,792,458}\cdot 1\;[\mathrm{s}]=\frac{9,192,631,770}{299,792,458}\frac{c}{\Delta\nu_{\mathrm{Cs}}}\cong 30.663319\frac{c}{\Delta\nu_{\mathrm{Cs}}}\tag{9.1.2}$$

   The effect of this definition is that one metre is the length of the path travelled by light in vacuum during a time interval with duration of $1/299,792,458$ of a second.

2. The kilogram [kg] for the mass M (we will return back later to the definition of the concept of mass). Since 12018 (holocene calendar) it is defined by taking the fixed numerical value of the Planck constant h to be $6.62607015\cdot 10^{-34}$ when expressed in the unit $[\mathrm{J}\cdot\mathrm{s}^{-1}]$, which is equal to $[\mathrm{kg}\cdot\mathrm{m}^2\cdot\mathrm{s}^{-1}]$, where the metre and the second are defined in terms of c and $\Delta\nu_{\mathrm{Cs}}$. Hence:

$$1\;[\mathrm{kg}]=\frac{h}{6.62607015\cdot 10^{-34}}\cdot 1\;[\mathrm{m}^{-2}\cdot\mathrm{s}]=\frac{299,792,458^2}{9,192,631,770\cdot 6.62607015\times 10^{-34}}\frac{h\Delta\nu_{\mathrm{Cs}}}{c^2}\cong 1.4755214\cdot 10^{40}\frac{h\Delta\nu_{\mathrm{Cs}}}{c^2}\tag{9.1.3}$$

   The effect of this definition is to introduce the unit $\mathrm{kg}\cdot\mathrm{m}^2\cdot\mathrm{s}^{-1}$ (the unit of both the physical quantities of action and angular momentum). Together with the definitions of the second and the metre this leads to a definition of the unit of mass expressed in terms of the Planck constant h.

3. The second [s], for time T (time is not measurable in himself as it cannot be touched, but the time interval Δt is an arbitrary concept quite valid - we also will also return back on the definition of this concept further below). Since of 12018 (holocene calendar) it is defined by taking the fixed numerical value of the caesium frequency $\Delta\nu_{\mathrm{Cs}}$, the

unperturbed ground-state hyperfine transition frequency of the Caesium-133 atom, to be $9,192,631,770$ when expressed in the unit $[\text{Hz}]$, which is equal to $[\text{s}^{-1}]$. Hence:

$$1\,[\text{s}] = \frac{9,192,631,770}{\Delta\nu_{\text{Cs}}} \tag{9.1.4}$$

The effect of this definition is that the second is equal to the duration of $9,192,631,770$ periods of the radiation corresponding to the transition between the two hyperfine levels of the unperturbed ground state of the ^{133}Cs atom.

4. The Coulomb [C] used as a fundamental unit of electric charge $q_e = 1.602176634 \cdot 10^{-19}$ (not derived from any known at this date - we will also return to the definition of this concept further below).

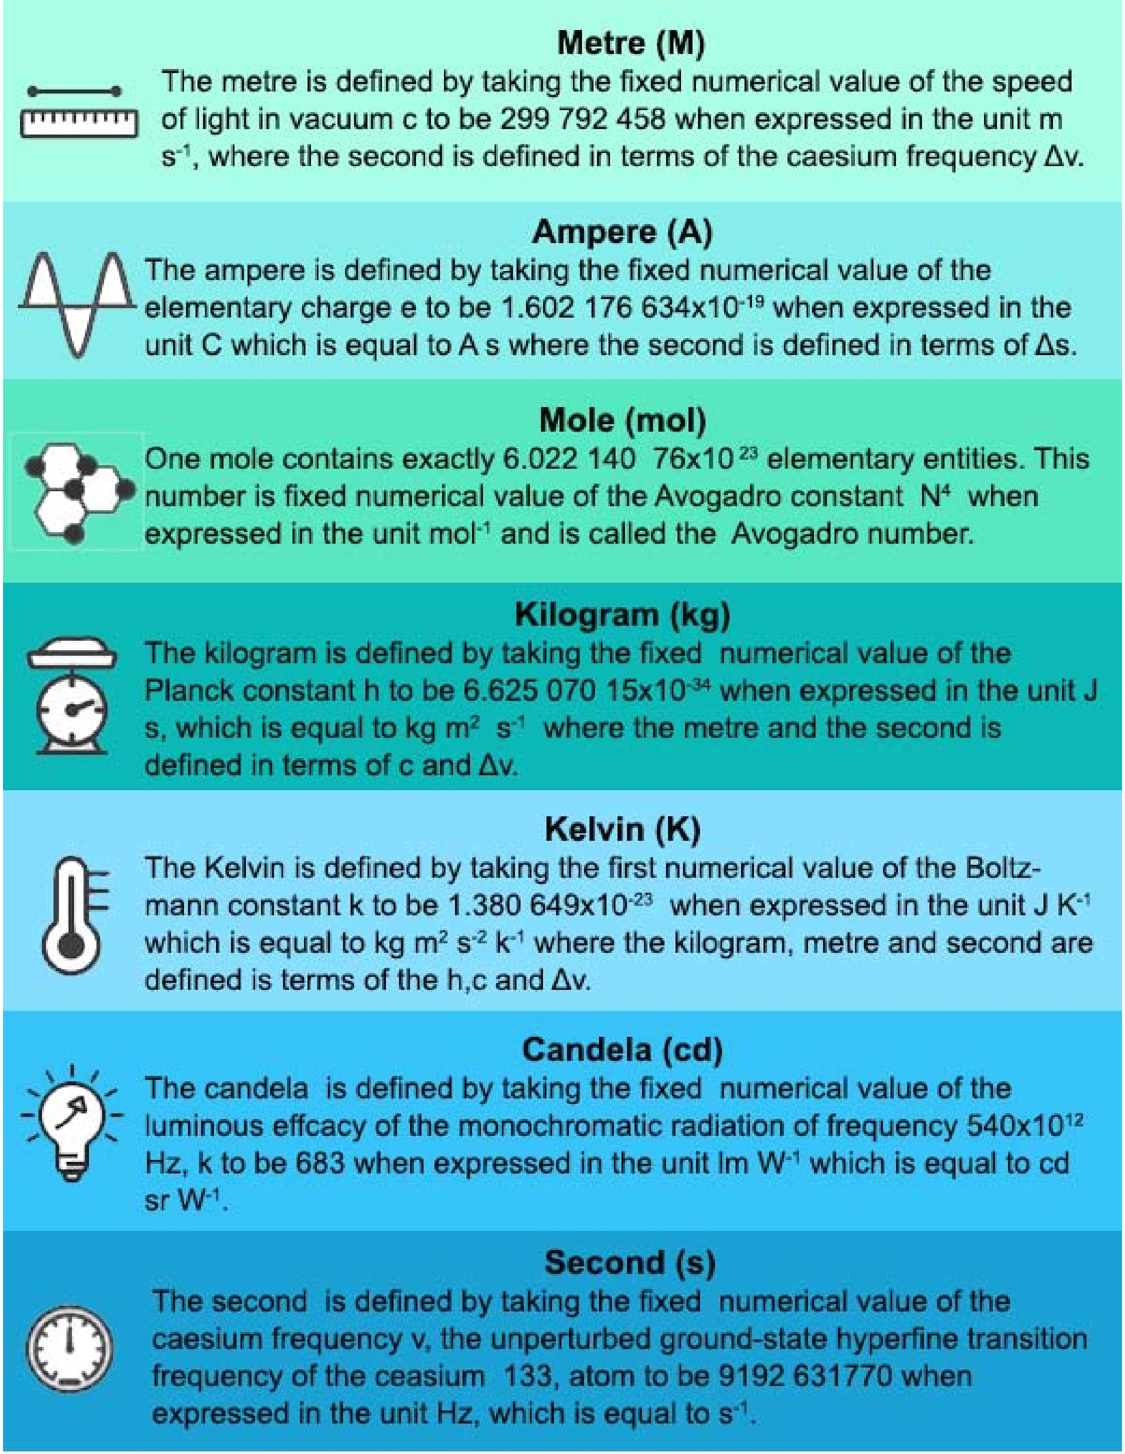
Remark

The electric charge isn't listed among the 19 free parameters of the Standard Model of particles because it's not put in by hand-it, it emerges naturally from deeper symmetries in the theory and therefore isn't something fundamental in reality... The electric charge arises from a combination of two of the gauge coupling constants g_1 and g_2. From there we can calculate a fine-structure constant, as per:

$$\alpha = \frac{1}{4\pi}\frac{(g_1 g_2)^2}{g_1^2 + g_2^2} \tag{9.1.5}$$

which then is proportional to the elementary charge squared, i.e. $\alpha \propto e^2$.

The 12019 (holocene calendar) redefinition of the SI base units came into force on 20 May 12019. It can be summarized by the following figure (see [206] for more details):



Metre (M)

The metre is defined by taking the fixed numerical value of the speed of light in vacuum c to be 299 792 458 when expressed in the unit m s^{-1}, where the second is defined in terms of the caesium frequency Δv.

Ampere (A)

The ampere is defined by taking the fixed numerical value of the elementary charge e to be 1.602 176 634x10^{-19} when expressed in the unit C which is equal to A s where the second is defined in terms of Δs.

Mole (mol)

One mole contains exactly 6.022 140 76x10^{23} elementary entities. This number is fixed numerical value of the Avogadro constant N^4 when expressed in the unit mol^{-1} and is called the Avogadro number.

Kilogram (kg)

The kilogram is defined by taking the fixed numerical value of the Planck constant h to be 6.625 070 15x10^{-34} when expressed in the unit J s, which is equal to kg m^2 s^{-1} where the metre and the second is defined in terms of c and Δv.

Kelvin (K)

The Kelvin is defined by taking the first numerical value of the Boltzmann constant k to be 1.380 649x10^{-23} when expressed in the unit J K^{-1} which is equal to kg m^2 s^{-2} k^{-1} where the kilogram, metre and second are defined is terms of the h,c and Δv.

Candela (cd)

The candela is defined by taking the fixed numerical value of the luminous effcacy of the monochromatic radiation of frequency 540x10^{12} Hz, k to be 683 when expressed in the unit lm W^{-1} which is equal to cd sr W^{-1}.

Second (s)

The second is defined by taking the fixed numerical value of the caesium frequency v, the unperturbed ground-state hyperfine transition frequency of the ceasium 133, atom to be 9192 631770 when expressed in the unit Hz, which is equal to s^{-1}.

Figure 9.3: Based 12019 SI

The reader has to known that since its adoption into the International System of Units in 11971 (holocene calendar), criticisms of the concept of the mole as a unit like the metre or the second have arisen as the number of molecules, etc. in a given amount of material is a fixed dimensionless quantity that can be expressed simply as a number, not requiring a distinct base unit. Therefore the mole is not a true metric (i.e. measuring) unit, rather it is a parametric unit, and amount of substance is a parametric base quantity. We can only hope that in the future this unit will be removed.

Remarks

R1. The concept of angle θ (in radians, degrees or steradians - see the texts on plane trigonometry, spherical trigonometry and plane geometry in the chapter Geometry starting at page 2503) since it has no unit because by definition its a ratio of lengths (for the radian or degree of angle) or surfaces (for the steradian). It is therefore appropriate to assimilate it to a derived unit and not as fundamental unit. However, in physics, we have sometimes the habit to indicate its presence in the dimensional equations to help re-reading some of them and to know that their result is given with respect to an angle unit (otherwise it could risky generate misinterpretations for those using the equations without have read the proof...).

R2. The development of science has led the General Conference of Weights and Measures to introduce some additional practices (but not necessary) units such as (among others as you can see it in the previous figure) the temperature in "Kelvin" [K] (derived from the average energy - Brownian motion), the amount of expressed in terms Moles, the current intensity in Ampere [A] and the light intensity expressed in Candelas [cd]. Thus, the actual International System (SI) with its seven fundamental base units (kilogram-meter-second, kelvin, candela, mole and ampere) and its seventeen-derived units does it suggests that seven units are needed to describe all physics? Actually no! As the Gauss analysis suggests it, among the seven fundamental units, four of them - Kelvin, Candela, the Mole and the Ampere - can be derived from the other three. The introduction of seven base units represents a pragmatic balance between experimentalists who require units adapted to their measures, and idealism theorists, whose goal is to reduce arbitrary redundancy to a minimum.

R3. This is a huge chance to have a homogeneous system such as we have in the 121st century (holocene calendar). Indeed, for the record, in 11522 (holocene calendar) alone in the Baden-Baden area (Germany) there were 112 units of measures for the concept of length and 92 units of measures for the concept of area.... that is to say the mess... a nightmare! In the early 121st century (holocene calendar) there are ISO 80000 norms which aim to harmonize the notations, definitions and values of units in all fields of sciences.

These clarifications done, any physical quantity known at this date can be expressed using a unit which is expressed as the product at a given power (positive or negative power!) of the five fundamental dimensional factors and an arbitrary scale factor K (dimensionless number, which acts as a proportionality factor for taking from a scale, that of the fundamental unit, to that of the studied variable):

$$K\cdot[M]^m\cdot[L]^l\cdot[T]^t\cdot[\theta]^\theta\cdot[C]^c \tag{9.1.6}$$

where the numbers m,l,t,θ,c named respectively "mass order", "length order", "time order", "angle order" and "charge order" are positive, negative or zero integers (for the huge majority of cases!).

The above expression will be written in the "canonical form" defined by the standard units:

$$K\cdot[\text{kg}]^m\cdot[\text{m}]^l\cdot[\text{s}]^t\cdot[\text{C}]^c \tag{9.1.7}$$

the angle having no units, we don't write it anymore (but can be still here implicitly depending on the context!).

Any physical quantity X is therefore expressed as:

$$x = x \cdot K \cdot [\text{kg}]^m \cdot [\text{m}]^l \cdot [\text{s}]^t \cdot [\text{C}]^c \tag{9.1.8}$$

where x is the magnitude of the physical quantity in the unit system associated with the scaling factor K. There are several possible pairs (x, K), but we will always have:

$$x \cdot K = x_0 = c^{te} \tag{9.1.9}$$

where the constant x_0 is the value of the physical magnitude when we choose to express it in the system M.K.S.C.

So two physical quantities are homogeneous if and only if the quadruplets:

$$(m_1, l_1, t_1, c_1), (m_2, l_2, t_2, c_2) \tag{9.1.10}$$

that are linked to them are equals:

$$m_1 = m_2 \quad l_1 = l_2 \quad t_1 = t_2 \quad c_1 = c_2 \tag{9.1.11}$$

It follows from what we have said, that:

- The sum or difference of any number of quantities is meaningful only if these quantities are homogeneous and the result will have the same units as the operands.
- The product or division of multiple quantities has for units respectively the product or division of the operands units.

Remark

The units of the different quantities have a practical side but not infallible in theoretical physics: they nevertheless allow the physicist to verify whether a proven relation between two quantities is at least correct at the unit level. We name this kind of approach a "dimensional analysis" (we advise you to go see the proof of the Stokes law in the section of Continuum Mechanics at page 3853 for a very good example of application).

For a little summary:

Basic units

Quantity	Unit	Sym.
Length	meter	m
Mass	kilogram	kg
Time	second	s
Therm. temp.	kelvin	K
Electr. current	ampere	A
Luminous intens.	candela	cd
Amount of subst.	mol	mol

Extra units

Plane angle	radian	rad
Solid angle	sterradian	sr

Derived units with special names

Quantity	Unit	Sym.	Derivation
Frequency	hertz	Hz	s^{-1}
Force	newton	N	$kg \cdot m \cdot s^{-2}$
Pressure	pascal	Pa	$N \cdot m^{-2}$
Energy	joule	J	$N \cdot m$
Power	watt	W	$J \cdot s^{-1}$
Charge	coulomb	C	$A \cdot s$
El. Potential	volt	V	$W \cdot A^{-1}$
El. Capacitance	farad	F	$C \cdot V^{-1}$
El. Resistance	ohm	Ω	$V \cdot A^{-1}$
El. Conductance	siemens	S	$A \cdot V^{-1}$
Mag. flux	weber	Wb	$V \cdot s$
Mag. flux density	tesla	T	$Wb \cdot m^{-2}$
Inductance	henry	H	$Wb \cdot A^{-1}$
Luminous flux	lumen	lm	$cd \cdot sr$
Illuminance	lux	lx	$lm \cdot m^{-2}$
Activity	bequerel	Bq	s^{-1}
Absorbed dose	gray	Gy	$J \cdot kg^{-1}$
Dose equivalent	sievert	Sv	$J \cdot kg^{-1}$

9.1.1.1 Dimensional Analysis

Dimensional analysis is an area of physics with that concerns the to units of the magnitudes. In particular, the fact that the units are relatively arbitrary makes that any valid equation of physics must be homogeneous: something that is measured in meters per second can not be equal to something that is measured in kilograms per meter. It is a very popular way and very effective way to check its own calculations (and that of others ...).

This statement, which can seem paradoxical, effectively means: Do not start (if possible ...) in a complicated calculation without finding beforehand the qualitative form of the result with dimensional analysis.

This qualitative form is traditionally named the "dimensional equation" and thus represents the formula that gives the possibility to determines the unit in which the result must be expressed in a research. This is an equation of variables (quantities/magnitudes), that is to say, in which the measured phenomena are represented by a unit symbol those we have seen in the previous paragraphs.

✍**Example:**

Let's see an example of a legend (?) often quoted in magazines and popular books:

Dimensional analysis should have enabled G. I. Taylor in 11950 (holocene calendar) to estimate the energy released by the explosion of an atomic bomb (first detonation of a nuclear weapon in July 16, 11945 (holocene calendar): code name "Trinity", tested in the Jornada del Muerto desert), while this information was classified top secret, it would have been enough for him to watch a movie of the explosion, unwisely made public by the US military.

The physicist G. I. Taylor suppose to arrive at this result that the process of expansion of the gas sphere depends at the minimum of the parameters of time t, the generated energy E by the explosion and the density of air ρ.

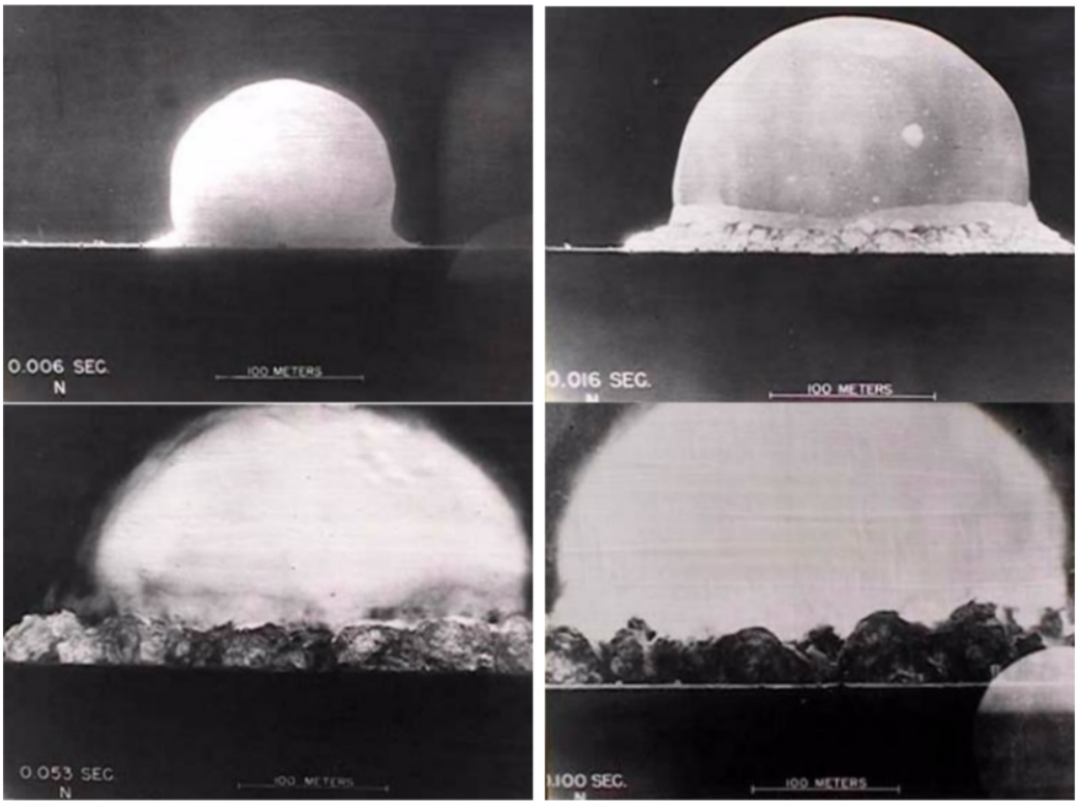


Figure 9.4: **Supposed picture used by G. I. Taylor for the estimation (source: ?)**

Dimensional analysis then conducted him for the radius of the sphere of gas at time t to:

$$r\,[\mathrm{m}] = k \cdot \left(E\,[\mathrm{kg}\cdot\mathrm{m}^2\cdot\mathrm{s}^{-2}]\right)^x \cdot \left(\rho\,[\mathrm{kg}\cdot\mathrm{m}^3]\right)^y \cdot \left(t\,[\mathrm{s}]\right)^z \tag{9.1.12}$$

where k is a dimensionless constant.

And by trial and error we find relatively quickly $x = 1/5, y = -1/5, z = 2/5$ such as:

$$r = kE^{1/5}\rho^{-1/5}t^{2/5} \tag{9.1.13}$$

Indeed:

$$m = \left(\mathrm{kg}^{1/5}\cdot\mathrm{m}^{2/5}\cdot\mathrm{s}^{-2/5}\right)\cdot\left(\mathrm{kg}^{-1/5}\cdot\mathrm{m}^{3/5}\right)\cdot\left(\mathrm{s}^{2/5}\right) \tag{9.1.14}$$

Taylor then finds the time dilation law of the radius of the atomic mushroom is proportional to (there is no need to indicate other units, since only the temporal part interests us here!):

$$r \propto t^{2/5} \tag{9.1.15}$$

If we know r and t from a film, and k being supposed to be of the order of the unit and ρ being known, we finally get:

$$E \cong \frac{\rho r^5}{t^2} \tag{9.1.16}$$

what remains a rough approximation. But getting such a result (of magnitude) with the heavy artillery of theoretical physics would require much more time and paper.

As we can see in the example above, the power of units aren't always an integer! The most well-known case of non-integer dimension units are first the one in financial engineering (Value at Risk) involving de square root of time (i.e. $[\text{s}^{1/2}]$) and the second most well known one is in fiber optics technology (polarization mode dispersion coefficient) involving an inverse of square root distance (i.e. $[\text{s}^{-1/2}]$).

9.1.1.1.1 Time

Definition (#9.1.406): The "time" is a state variable (not a "measurable") and therefore a notion impalpable but however rigorously defined. It also is a mathematical tool to equate the observation of physical phenomena (observable) and thus draw some information. This tool exists because there are living beings to observe (and measure) the Nature and its changes (Socratic principle) and matter and movement for there to be changes. Time is therefore the indefinite continued progression of existence and events that occur in apparently irreversible succession from the past through the present to the future. The SI derived unit of time is the second [s]. Time is a component quantity of various measurements used to sequence events, to compare the duration of events or the intervals between them, and to quantify rates of change of quantities in material reality or in the conscious experience. Time is often referred to in General Relativity as one of the four dimensions, along with the three spatial dimensions (see section Special Relativity page 5627), when multiplied by the speed of light, of a four-dimensional pseudo-Riemmanian manifold.

Caution! As we will prove in the section of Quantum Gravity (see page 6087), the Wheeler-DeWitt model suggests that the universe as a whole may be timeless, and what we perceive as time is a local, emergent phenomenon that is not fundamental because as we know from General Relativity (see page 5720) there's no universal clock!

Remarks

R1. Time (and time intervals) being an arbitrary concept, it is symmetrical, that is to say that every phenomenon observed can be in the imagination of a possible inverted time finding his initial conditions. We speak then of "symmetry of time" (for now it has never been proven as far as we know that time may suffer of a "breaking symmetry"). In fact as we have seen in the section of Statistical Mechanics (see page 3658), the direction of time is defined by the concept of entropy and as the entropy can only increase (as far as we know), the question to go back in time is a non-sense (however in thermodynamic systems that are not closed, remember that entropy can decrease with time). We speak then of "thermodynamic time".

R2. Certain subatomic interactions involving the weak nuclear force violates the conservation of parity, but only very rarely. According to the CPT theorem, this means they should also be time irreversible, and so establish an arrow of time. This, however, is neither linked to the thermodynamic arrow of time, nor has anything to do with our daily experience of time irreversibility.

R3. If an intensive variable is one that is unchanged with the thermodynamic operation of scaling of a system (see section Thermodynamics page 3608) the time is not an intensive variable if we think to General Relativity (mass influence on time).

We represent very often in physics time (within a interval) by a horizontal arrow (axis). Since time is a relative concept, we can then define each instant of time as being zero time denoted t_0. This concept is very often used in physics because the only thing that interests physicists is the time difference denoted Δt (by the use of differential and integral calculus) or $\mathrm{d}t$ when the interval is very small.

Let us prove now that the time reference is independent of the choice for an observer at rest. Given a time denoted by the letter t, then we have:

$$\Delta t=(t_1+t')-(t_0+t')=t_1-t_0 \tag{9.1.17}$$

where t' is an arbitrary basis (not necessary) when we compare a temporal difference.

The time interval is given by a standard measure that can only be at best a perfectly periodic movement (repeated over time). So, the first means of measuring time were day and night..., the positions of the Sun (actually a G2V-type star, aka yellow dwarf) and Moon in the sky..., the pendulum, the relaxation of springs, the Cesium 137 degeneration period or even binary systems binaries of massive stars. In short, an observable system that produces a stable periodic phenomenon and small enough for any physical action that can be reduced to it can be used as a standard time interval!!!

Definitions (#9.1.407):

D1. An "event" consists to give meaning to a point in space-time (for a naive and technical definition of "space-time" see the section of Special Relativity at page 5708).

D2. Two events are say to be "simultaneous events" if they have the same value of the time coordinate.

D3. We name "coincidence" the simultaneity of two events at the same point in space. The coincidence is an absolute fact, independent of the choice of the repository. This is actually a particular case of the causal conservation principle. Two events coinciding in a referential frame may be the cause and effect of each other (and vice versa), and that possibility is retained in the new marker.

After Albert Einstein's Special Relativity (see section on the subject page 5627), time can no longer be thought of being absolute in all reference frames. Thus a watch that indicate one minute in one frame of reference will not be one minute in a reference frame that is travelling at a velocity relative to the first frame. This means that the time of an event is variable depending on the observer!

In high level physics, time (human creation) is always multiplied by the constant of speed of light c to get a distance and deal with it like a standard fourth dimension. As also in high level physics practitioners use natural units where among other $c=1$, then time is strictly and simply equal to length such that $t=\ell$.

9.1.1.1.2 Length

Definition (#9.1.408): The concept of "length", denoted most of the times x or sometimes ℓ, is given by the information that gives the path taken by an object in a given time interval or simply be the distance between two points. The SI derived unit of length is the meter [m].

Length may be distinguished from "height", which is vertical extent, and "width" or "breadth", which are the distance from side to side, measuring across the object at right angles to the length. Length is a measure of one dimension, whereas "area" is a measure of two dimensions (length squared) and "volume" is a measure of three dimensions (length cubed) as we will study this in details in the section of Euclidean Geometry (see page 2553). In most systems of measurement, the unit of length (meter) is a base unit, from which other units dimensions are defined.

Remarks

R1. If there was no matter in the Universe there would be no concept of movement and thus no path length and as we have already pointed it out, also no time (and again ... it is without considering some results of quantum physics that we will prove in the sections dedicated to it).

R2. Length is obviously an extensive quantity (additive). Indeed, the total length of an item is the sum of the length that composed it.

As for time, there is no absolute origin of length measurement (there is no "zero point" in the Universe as postulated, among others, by the theory of relativity) and physicists are interested anyway especially only to differences of travelled path Δx relative to an origin as they do for the time.

Thus, identically as for the time, we have for an observer at rest observing a moving material point:

$$\Delta x=(x_1+x')-(x_0+x')=x_1-x_0 \tag{9.1.18}$$

where x' is a mathematically arbitrary basis that is useless when comparing a difference of position in a time difference of a material point (as it cancels as you can see in the previous relation).

If a material point is located in a three dimensional space (the most frequent case in Classical

Mechanics, Astronomy, Astrophysics and Particle Physics) we arbitrarily chose an origin O, we note the position by of this body by $\vec{r}$, its distance in length by x, in width by y and in height by y (named "Cartesian coordinates" as we already know) by an imaginary arrow named "vector" (see section Vector Calculus page 1797) connecting the arbitrary origin of the reference frame to the interested point as follows:

$$\vec{r}=\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}=\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix} \tag{9.1.19}$$

Remark

The arrow above the $\vec{r}$ means of course that it is a vector!

The notation:

$$(x,y,z):=(x_1,x_2,x_3) \tag{9.1.20}$$

is a simplified notation used frequently in physics and who should prevail in small classes (take care! the fact that the numbers are in indices here, does not mean that they are covariant components - see section of Linear Algebra page 1956 - this is just a notation convention). However in this textbook we move from one to the other notations based on the needs and usage (it will be up to you to be careful to not confuse).

The matrix:

$$\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix} \tag{9.1.21}$$

is the metric tensor of a canonical pre-Euclidean space with positive signature (see section Vector Calculus page 1810 and General Relativity page 5731). This is a particular case in theoretical physics but still a very common case study in Classical Mechanics (you must start with simple spaces before going further...).

We will return in more detail on these concepts during our study punctual spaces further below.

After Albert Einstein's Special Relativity (see section on the subject page 5627), length can no longer be thought of being constant in all reference frames. Thus a ruler that is one meter long in one frame of reference will not be one meter long in a reference frame that is travelling at a velocity relative to the first frame. This means length of an object is variable depending on the observer!

Remark

All measurement apparatus that Humans use to measure other physical quantities are if you think about it related in one way or another to lengths (distance) comparisons. The fact that the measurement of a physical property can be reduced to a measurement of distance does not imply the non-existence of the physical phenomenon which produces the measured displacement. The measurement of the distance constitutes only our mode of access to the physical phenomenon in question. And this phenomenon can be explained independently of the measurement one makes of it!

Definition (#9.1.409): The "litre", SI symbols L, is a metric unit of volume. It is equal to 1 cubic decimetre (dm^3), $1,000$ cubic centimetres (cm^3) or 0.001 cubic metres (m^3). A cubic decimetre (or litre) occupies a volume of $10\,[\text{cm}]\cdot 10\,[\text{cm}]\cdot 10\,[\text{cm}]$. One litre of liquid water has a mass of almost exactly one kilogram, because the kilogram was originally defined in 11795 (holocene calendar) as the mass of one cubic decimetre of water at the temperature of melting ice ($0\,[^\circ\text{C}]$) at standard pressure conditions. Subsequent redefinitions of the metre and kilogram mean that this relationship is no longer completely exact.

9.1.1.1.3 Mass

In general the "mass" m of a body is in a closed system an amount which is preserved and that characterizes the amplitude with which a body interacts with other body through different (attractive) forces. The SI derived unit of the mass is the kilogram [kg].

> **Remark**
>
> In an isolated system and where there is no expansion of space-time, there can not be spontaneous creation or destruction of mass (however this is not the case for energy as we will see it during our study of the Casimir Effect in the section of Wave Quantum Physics at page 4825!).

But in most textbooks and classes we consider five type of masses.

Definitions (#9.1.410):

D1. The "invariant mass" or "proper mass" (also sometimes named "effective mass") denoted by m_0 is scalar quantity, an intrinsic property of a body (preserved by Poincaré transformations, and with some clauses, in General Relativity). It is constant for elementary subatomic particles (each species has its value of effective mass), as well as for atoms (and similar objects) on a specified energy level. It does not have a conservation law. It is not strictly constant for large bodies (for example, increases with heat because of the relation $E=mc^2$ that we will introduce later during our study of Special Relativity at page 5679).

D2. The "rest mass" m_0 is the same as invariant mass if it is positive. For particles with zero invariant mass, strictly speaking, rest mass is undefined (although both terms might be synonymous in colloquial speech)! A separate term is motivated by the fact that massive bodies, and only them, have their rest frames (may be also named "comoving frame").

D3. The "relativistic mass" is the implicit mass of the photon in its linear momentum p given by the Einstein's relation (see later our study of Special Relativity at page 5689). The "relativistic mass" must not be confused with the "apparent relativistic mass" given by γm_0 where γ is the Lorentz-Fitzgerald coefficient that we will introduce in our study of Special Relativity later (see page 5739).

Caution! We don't like the use of the word "photon", which dates from 11926 (holocene calendar) and was first used by the chemist Gilbert N. Lewis. In our view, there is no such thing as a photon that is useful when Quantum Electrodynamics is mastered at its finest! Only a comedy of errors and historical accidents led to the popularity of the word "photon" among physicists and optical scientists. However we admit that the word is short and convenient. Its use is also habit forming (similar objections are possible to use of the word "phonon", which dates from 11932).

D4. The "inertial mass" is the "m_i" thing in Newtonian mechanic (i.e. in the $F=m_ia$ relation that we will introduce later). Thought to be a conserved scalar quantity. For low speeds approximately equals to the rest mass m_0, but generally an obsolete concept since relativistic dynamics. Depending on context, is superseded in relativity either with the rest mass or (along momentum vectors) with 4-momenta. One can't consistently define inertial mass of a photon, for example.

D5. The "gravitational mass" m_g supposed as gravitational charge (for Newton's gravity law or some another theory). The interesting thing is that, physically, no difference has been found so far between gravitational and inertial mass. Many experiments have been performed to check the values and the experiments always agree to within the margin of error for the experiment. Albert Einstein used the fact that gravitational and inertial mass were equal to begin his theory of General Relativity (see page 5720) in which he postulated that gravitational mass was the same as inertial mass.

We also differentiate the "active gravitational mass" denoted M, from the "passive gravitational mass" denoted m in the Newton's gravitational law that we will introduce later (see page 5255):

$$F=m\frac{GM}{r^2} \tag{9.1.22}$$

But by the Newton's third law (see page 3209) lead us to assume (and this is verified experimentally!) that both mass (active and passive) are equivalent such that we can also write:

$$F=M\frac{Gm}{r^2} \tag{9.1.23}$$

Hence the fact that we speak only and simply about the "gravitational mass" (without specifying if it is active or passive since they seem to be equivalent).

Remarks

R1. Experiments have shown that the inertial and gravitational masses were proportional to the ten-billionth. This experimental identity named "Galilean principle of equivalence" is the basis of the postulates of General Relativity (see section of the same name page 5720) such that we assume:

$$m_i=m_g \tag{9.1.24}$$

that we denote simply by the letter m.

R2. Unlike electric charges (see further below the definition of "electric charge"), which characterize the amplitude of interaction by the electric force, it seems that they are only positive masses. Indeed, the electric charges can push or attract between them.

There are other type of masses like the "Bare Mass" and the "Self Energy Mass" in Quantum Physics but they are actually out of the scope of this textbook!

In addition, the mass being an additive property (so "extensive" as we have already said) of matter, for a system of n masses m_i $(i=1\ldots n)$, the total mass is:

$$M_{\text{tot}}=\sum_{i=1}^{n} m_i \tag{9.1.25}$$

Similarly, for a continuous volume distribution, the total mass of a system of volume V is given by:

$$M_{\text{tot}}=\iiint\limits_{V}\rho_V(A)\mathrm{d}V=\iiint\limits_{V=\{A|\vec{r}=\overrightarrow{\mathrm{O}A}\}}\rho(\vec{r})\circ\mathrm{d}^3\vec{r} \tag{9.1.26}$$

where $\rho_V(A)$ is the "mass density" or "volume density" of the system at point A and where $\rho_V(\vec{r})$ is the density of the system at the point indicated by $\vec{r}=\overrightarrow{\mathrm{O}A}$ (this is what is meant in the braces below the second triple integral).

Remarks

R1. The triple integral (on the three dimensions of space), can be reduced to a simple integral when exploiting the possible symmetries of the system.

R2. The calculation of the mass in a non-continuous distribution (discrete) material should be done with the vector components calculated separately. Once done, then it is appropriate to take the norm.

Therefore $\rho_V(A)$ is the mass density of a material elements, centered around A, of characteristic dimensions of those of the system, but large compared to the inter-atomic distances in the system defined by:

$$\rho_V=\frac{\mathrm{d}m}{\mathrm{d}V} \tag{9.1.27}$$

If the system is homogeneous we have obviously:

$$\rho_V=\frac{M_{\text{tot}}}{V} \tag{9.1.28}$$

Remark

The mass density is an intensive quantity. Indeed, the density of a physical system is not equal to the sum of these densities (this is common sense!). The reader will notice that this intensive quantity that is the density is the ratio of two extensive quantities.

Definitions (#9.1.411):

D1. We say that a system is a "massic homogeneous system" if its volumetric, surfacic, linear densities (see definition below) are constant on any small element of volume that constitute it.

D2. We say that a system is an "isotropic system", if its physical properties are identical in all points and directions.

We also define sometimes the "surfacic mass density" (or simply "surfacic density") for systems with virtually no thickness and a "linear mass density" (or simply "linear density") for systems with also negligible width relatively to their length. We then have (S being a surface and s curvilinear abscissa):

$$M_{\text{tot}}=\iint\limits_S \rho_S(A)\mathrm{d}S=\iint_S \rho_S(\vec{r})\mathrm{d}^2\vec{r} \quad \text{and} \quad M_{\text{tot}}=\int\limits_L \rho_L(s)\mathrm{d}s=\int\limits_L \rho_L(\vec{r})\mathrm{d}\vec{r} \qquad (9.1.29)$$

with in the general case:

$$\rho_S=\frac{\mathrm{d}m}{\mathrm{d}S} \qquad \rho_L=\frac{\mathrm{d}m}{\mathrm{d}L} \qquad (9.1.30)$$

If the system is homogeneous we have again obviously with the traditional notation:

$$\sigma:=\rho_S=\frac{M}{S} \qquad \gamma:=\rho_L=\frac{M}{L} \qquad (9.1.31)$$

Remark

Notice the interesting following relationship with the delta Dirac function (see section Differential and Integral Calculus page 1569) if we take the special case of linear density (but the same can be generalized to the volumic case!):

$$\int\limits_{-\infty}^{+\infty}\rho(x)\mathrm{d}x=\int\limits_{-\infty}^{+\infty}m\delta(x)\mathrm{d}x=m \qquad (9.1.32)$$

Hence:

$$\rho(x)=m\delta(x) \qquad (9.1.33)$$

This relationship is also used a lot in quantum field theory with the energy density rather than the mass density.

Definition (#9.1.412): With the above, we can define the "density" as the number of identical elements and all countable per unit volume, or unit surface or unit linear.

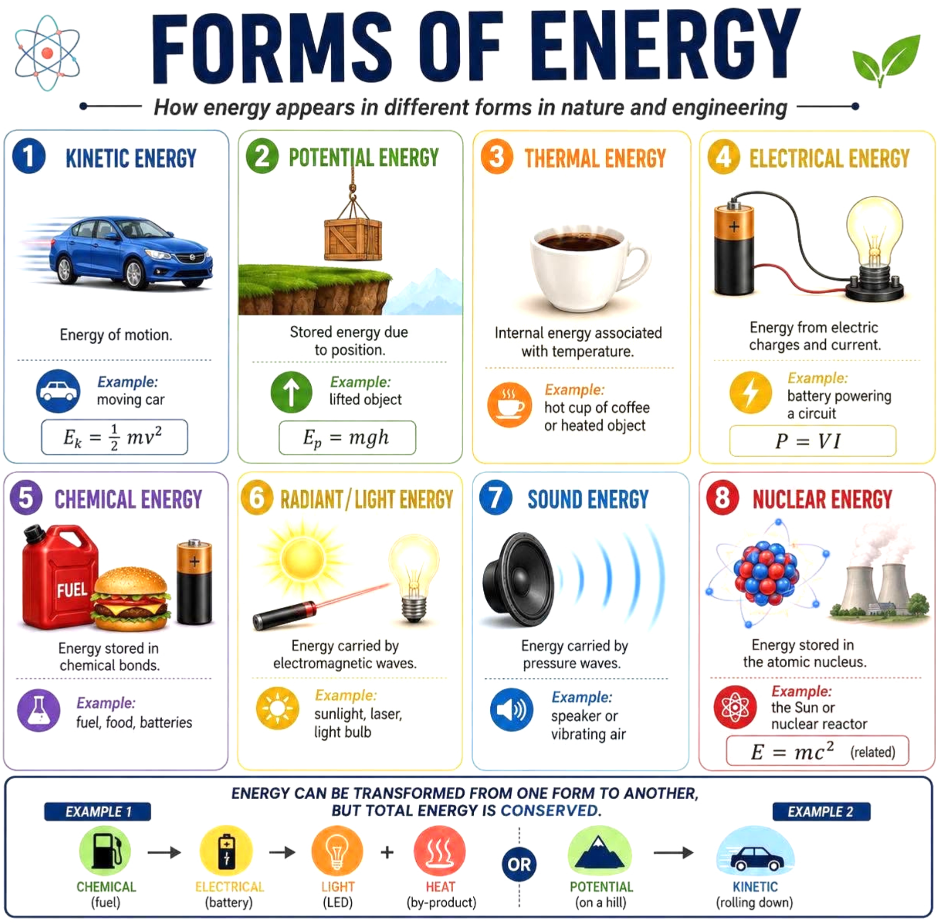
The density of a material varies with temperature and pressure. This variation is typically small for solids and liquids but much greater for gases. Increasing the pressure on an object decreases the volume of the object and thus increases its density. Increasing the temperature of a substance (with a few exceptions) decreases its density by increasing its volume. In most materials, heating the bottom of a fluid results in convection of the heat from the bottom to the top, due to the decrease in the density of the heated fluid. This causes it to rise relative to more dense unheated material.

Caution! The opinion that everything in our Universe is made of mass, opinion named in philosophy "materialism", has been definitely proven wrong with the confirmation of the discovery of the Higgs boson (and its corresponding field) the 4th July 12022 (holocene calendar) at CERN in Geneva (Switzerland). We know today that the mass is a property acquired by the excitation of the various existing quantum fields through another quantum field named the "Higgs field". The Brout-Englert-Higgs mechanism (11964 according to holocene calendar) introduced the Higgs field, whose quantum manifestation is the Higgs boson. Only particles that interact with the Higgs field acquire mass! The Higgs mechanism therefore makes it misleading to speak of the mass of such and such a particle, since mass is no longer an intrinsic property of elementary particles, but a measure of their interactions with the Higgs field.

9.1.1.1.4 Energy

We still do not know what exactly is energy (denoted in its general form with the letter E) but we know its effects. What we know however is that the energy can be classified can be transferred partially to other objects or converted into different forms. The main common forms being:

- "Work Energy" which is the energy generated by the application of a force on a body giving it a certain kinetic energy (thermal[2], electric kinetic energy) or potential energy (gravitational, electrostatic, magnetic potential energy) as studied in the sections of Classical Mechanics, Astronomy, Electrostatics, Electrodynamics, Thermodynamics and Continuum Mechanics.
- "Heat Energy" which is a form of energy determined by the number of micro-states of a system as seen in the sections of Thermodynamics and Statistical Mechanics.
- "Mass Energy" is the energy contained in a certain amount of mass (nuclear energy, chemical energy) as seen in the sections of Special Relativity and Statistical Mechanics.
- "Radiation energy" is the energy held in light waves (electromagnetic wave of a particle without rest mass), allowing them to travel across space.



FORMS OF ENERGY
How energy appears in different forms in nature and engineering
1 KINETIC ENERGY
Energy of motion.
Example: moving car
$E_k = \frac{1}{2}mv^2$
2 POTENTIAL ENERGY
Stored energy due to position.
Example: lifted object
$E_p = mgh$
3 THERMAL ENERGY
Internal energy associated with temperature.
Example: hot cup of coffee or heated object
4 ELECTRICAL ENERGY
Energy from electric charges and current.
Example: battery powering a circuit
$P = VI$
5 CHEMICAL ENERGY
FUEL
Energy stored in chemical bonds.
Example: fuel, food, batteries
6 RADIANT/LIGHT ENERGY
Energy carried by electromagnetic waves.
Example: sunlight, laser, light bulb
7 SOUND ENERGY
Energy carried by pressure waves.
Example: speaker or vibrating air
8 NUCLEAR ENERGY
Energy stored in the atomic nucleus.
Example: the Sun or nuclear reactor
$E = mc^2$ (related)
ENERGY CAN BE TRANSFORMED FROM ONE FORM TO ANOTHER, BUT TOTAL ENERGY IS CONSERVED.
EXAMPLE 1
CHEMICAL (fuel)
ELECTRICAL (battery)
LIGHT (LED)
HEAT (by-product)
OR
EXAMPLE 2
POTENTIAL (on a hill)
KINETIC (rolling down)

---

[2] The virial theorem, as proved in the section of Continuum Mechanics page 3897, indicates the absolute temperature as proportional to the average kinetic energy of the random microscopic motions of those of their constituent microscopic particles, such as electrons, atoms, and molecules, that move freely within the material.

The total energy of a system can be subdivided and classified in various ways. For example, Classical Mechanics distinguishes between kinetic energy, which is determined by an object's movement through space, and potential energy, which is a function of the position of an object within a field. It may also be convenient to distinguish gravitational energy, thermal energy, several types of nuclear energy (which utilize potentials from the nuclear force and the weak force), electric energy (from the electric field), and magnetic energy (from the magnetic field), among others. Many of these classifications overlap; for instance, thermal energy usually consists partly of kinetic and partly of potential energy.

Some types of energy are a varying mix of both potential and kinetic energy. An example is mechanical energy which is the sum of (usually macroscopic) kinetic and potential energy in a system. Elastic energy in materials is also dependent upon electrical potential energy (among atoms and molecules), as is chemical energy, which is stored and released from a reservoir of electrical potential energy between electrons, and the molecules or atomic nuclei that attract them..The list is also not necessarily complete. Whenever physical scientists discover that a certain phenomenon appears to violate the law of energy conservation, new forms are typically added that account for the discrepancy.

Potential energies are often measured as positive or negative depending on whether they are greater or less than the energy of a specified base state or configuration such as two interacting bodies being infinitely far apart. Wave energies (such as radiant or sound energy), kinetic energy, and rest energy are each greater than or equal to zero because they are measured in comparison to a base state of zero energy: "no wave", "no motion", and "no inertia", respectively.

We can still try to ask ourselves what is exactly energy?

Definition (#9.1.413): The "energy" is the observable of the result of dynamic patterns of modifications or a conservation property of a system (many textbooks define energy as the variation of work but this is circular definition). These dynamic patterns may not be necessarily deterministic and of zero mean and conservative in a closed system! The SI derived unit of energy is the Joule [J]. It is also common in Nuclear Physics, Plasma Physics and Particle Physics to use the electron-volt that is by definition the energy gain by a charge of a single electron moving across an electric potential difference of one volt and equal to $1.602176634\cdot 10^{-19}$ [J] (see section Nuclear Physics page 5027).

It is essential to exercise caution when encountering assertions from individuals such as charlatans, enthusiasts, popular science publications, and some engineers, who claim that «*everything is energy!*». Contemporary scientific evidence disproves this assertion, as numerous fundamental properties of nature cannot be solely described in terms of energy. These include angular momentum and momentum (which are two of the three conserved quantities explained by Noether's theorem, the third being energy), spin, quark colors, the chirality of photons, the polarity of light, and neutrino flavors among many others. Consequently, you will not find any peer-reviewed papers in prestigious scientific journals like Physical Review Letters stating «*everything is energy!*», as such a statement is simply incorrect. An ancient Greek proverb states «*Mēden agan*», which can be translated to «*Excess is wisdom's enemy*». As always, excessive simplification indeed makes things simpler—but at the risk of drawing conclusions that verge on absurdity.

As we will see in the section of Analytical Mechanics during our study of Lagrangian formalism, the energy can be defined as the conserved quantity associated with time translation symmetry of the Lagrangian (see page 3132).

Remarks

R1. The mass and energy are equivalent as we will see during our study of Special Relativity (see section Special Relativity page 5627), if we define a system of units such that the speed of light system is $c = 1$ (widely used convention by physicists in advanced research) the mass is then just equal to the energy when at rest (since $E = mc^2$ in natural units becomes $E = m$)!

R2. The energy, in the same way that mass, is an extensive quantity.

R3. In an isolated system and in a static space-time, they cannot be spontaneous creation or destruction of energy by definition. Spontaneous apparition of energy can only be due to an external action in such a system. Another way of saying the same thing is that the total energy in the Universe is constant if the latter is considered as isolated and not expanding.

R4. In certain study fields, such as plasma physics and particle physics, it is sometimes common to convert the electron-volt (energy) as a unit of temperature as it helps for comparison analysis with an intuitive everyday life quantity (we will have such examples in this textbook). The conversion to the Kelvin scale is defined by using the Boltzmann constant k (see section Continuum Mechanics page 3921):

$$\frac{1\,[\text{eV}]}{k} = \frac{1.602176634 \cdot 10^{-19}\,[\text{J}]}{1.380649 \cdot 10^{-23}\,[\text{J} \cdot \text{K}^{-1}]} \cong 11604.518121\,[\text{K}] \tag{9.1.34}$$

For more detail and a criticism of the conversion, the reader must refer to the section of Nuclear Physics.

To finish, let us notice that as the mass and energy are equivalent to a given factor (c), we can obviously also define an energy volumetric density, energy surfacic density and energy linear density with also the same three remarks that apply.

You will notice in all calculations in this textbook that the Boltzmann constant $k = 1.380649 \cdot 10^{-23}\,[\text{m}^2 \cdot \text{kg} \cdot \text{s}^{-2} \cdot \text{K}^{-1}]$ and T almost always shows up together; it's no accident, k is just a dummy factor which converts energy to temperature. That's why in high level physics, practitioners use natural units where $k = 1$ such that $E = T$.

9.1.1.1.5 Electric Charge

It is difficult to say something about the electric charge (you can search a definition on Internet you'll see ...). However, if we refer to the approach of theoretical physicist Hideki Yukawa we can try to give the following definition:

Definition (#9.1.414): The "electric charge" q seems to be a conservative physical property of matter that causes it to experience a force when placed in an electric or magnetic field. There are two types of electric charges: positive and negative. Like charges repel and unlike attract. An object (one not made of antimatter) is negatively charged if it has an excess of electrons, and is otherwise positively charged or uncharged. The SI derived unit of electric charge is the coulomb [C]. In electrical engineering, it is also common to use the ampere-hour [Ah], and, in chemistry, it is common to use the elementary charge (e) as a unit. The symbol Q often denotes multiple electric charges. Early knowledge of how electrically charged substances interact is now named "Classical Electrodynamics" (see section Electrodynamics page 4094), and is still accurate for problems that don't require consideration of quantum effects (see section Quantum Field Theory page 5192).

More technically... (we refer to what we will see in the section of Quantum Field Theory at page 5158) an another but still not accurate definition is to say that: An "electric charge" q is a conservative property that has a particle lying in a spherically symmetric potential field to interact with the source of that field in the context of the exchange of a quantum of interaction (the photon is the quantum of this interaction generated by the quantum fluctuations of vacuum in the presence of a mass) defining a vector field of the Coulomb type.

Or another definition similar to that of the mass: The "electric charge" q of a body in a closed system is a conservative quantity and that characterizes algebraically the amplitude with which the body interacts with other body through electrostatic and magnetic forces.

The electric charge is a fundamental conserved property of some subatomic particles, which determines their electromagnetic interaction. Electrically charged matter is influenced by, and produces, electromagnetic fields. The interaction between a moving charge and an electromagnetic field is the source of the electromagnetic force, which is one of the four fundamental forces.

Remarks

R1. In an isolated system, globally they cannot be spontaneous creation or removal of electric charges. The emergence of electric charges can only be due to an external action as far as we know. Another way of saying the same thing - as for the mass - is that the total charge contained an isolated system seems to be constant.

R2. The charge is an extensive quantity. Indeed, the total electric charge of a physical system is equal to the algebraic sum of the charges which constitutes it.

120th century (holocene calendar) experiments demonstrated that electric charge is quantized; that is, it comes in integer multiples of individual small units named the "elementary charge", e, approximately equal to $1.602176634 \cdot 10^{-19}$ [C] (except for particles named quarks, which have charges that are integer multiples of $e/3$). The proton has a charge of $+e$, and the electron has a charge of $-e$. The study of charged particles, and how their interactions are mediated by photons, is named "Quantum Electrodynamics" (see section Elementary Particle Physics page 5194).

As already mentioned, contrary to the mass, there are positive and negative electric charges this is why we use the term "algebraic". The electric charge remains an additive property (extensive). Thus, for a system of q_i electric charges, the total electric charge is therefore:

$$Q := Q_{\text{tot}} = \sum_{i=1}^{n} \pm q_i \tag{9.1.35}$$

The electric charge of a macroscopic object is the algebraic sum of the electric charges of the particles that make it up. This charge is often small, because matter is made of atoms, and atoms typically have equal numbers of protons and electrons, in which case - if the distribution of charges can be considered as homogeneous[3] - their charges cancel out, yielding a net charge of zero, thus making the atom neutral.

Similarly as for the mass and the energy, for a total continuous volumetric distribution of the electric charge of a system of volume V (we denote the electric charge density in an identical way as that of the mass if the ambiguity is not possible):

$$Q_{\text{tot}} = \iiint_V \rho_V(A)\mathrm{d}V = \iiint_{v=\{A|\vec{r}=\overrightarrow{\mathrm{O}A}\}} \rho_V(\vec{r}) \circ \mathrm{d}^3\vec{r} \tag{9.1.36}$$

where $\rho_V(A)$ is the "volumetric electric charge density" of the system at point A, that is to say the electric charge of a material element, centered around A, of characteristic dimensions in comparison to that of the system, but large in comparison of the inter-atomic distances in this system ($\rho_V(\vec{r})$ is the volumetric density of electric charges of the system to the point indicated by $\vec{r} = \overrightarrow{\mathrm{O}A}$) defined by:

$$\rho_V = \frac{\mathrm{d}q}{\mathrm{d}V} \tag{9.1.37}$$

with also the same three remarks that apply.

As for the mass, we can give the following definitions:

Definitions (#9.1.415):

D1. We say that a system is an "electric homogeneous system" if its volumetric, surfacic, linear charge densities (see definition below) are constant on any small element of volume that constitute it.

D2. We say that a system is an "electric isotropic system", if its electric properties are identical in all points and directions.

---

[3] For example the disposition of the quarks in the Neutron is not homogeneous this is why even if the Neutron seems... neutral under a strong magnetic field the neutron will have a precession movement and this is why even if the neutron has an electric charge that is to weak to be deviated by a magnetic field it is not small enough to hide the Larmor effect.

We also define sometimes the "electric charge surfacic density" (or simply "surfacic density") for systems with virtually no thickness and a "electric charge linear density" (or simply "linear density") for systems with also negligible width relatively to their length. We then have (S being a surface and s curvilinear abscissa):

$$Q_{\text{tot}}=\iint\limits_S \rho_S(A)\mathrm{d}S=\iint_S \rho_S(\vec{r})\mathrm{d}^2\vec{r} \quad \text{and} \quad Q_{\text{tot}}=\int\limits_L \rho_L(s)\mathrm{d}s=\int\limits_L \rho_L(\vec{r})\mathrm{d}\vec{r} \tag{9.1.38}$$

with in the general case:

$$\rho_S=\frac{\mathrm{d}q}{\mathrm{d}S} \qquad \rho_L=\frac{\mathrm{d}q}{\mathrm{d}L} \tag{9.1.39}$$

If the system is electrically homogeneous we have again obviously with the traditional notation:

$$\sigma:=\rho_S=\frac{Q}{S} \qquad \gamma:=\rho_L=\frac{Q}{L} \tag{9.1.40}$$

Definition (#9.1.416): With the above, we can define the "electric density" as the number of identical elements and all countable per unit volume, or unit surface or unit linear.

The electric charge density of a material varies, as for the mass, with temperature and pressure. This variation is typically small for solids and liquids but much greater for gases. Increasing the pressure on an object decreases the volume of the object and thus increases its density. Increasing the temperature of a substance (with a few exceptions) decreases its density by increasing its volume. In most materials, heating the bottom of a fluid results in convection of the heat from the bottom to the top, due to the decrease in the density of the heated fluid. This causes it to rise relative to more dense unheated material.

9.1.1.2 Scientific Notation and Metric Prefixes

Ok just now we have defined the concept of quantity/magnitude and associated main units as used by the physicists and engineers. But what about the scientific notation for big numbers (magnitudes) and associated metric prefixes??? Let us see this now!

Scientific notation (also referred to as standard form or standard index form) is a way of expressing numbers that are too big or too small to be conveniently written in decimal form. It is commonly used by scientists, mathematicians and engineers. On scientific calculators it is known as "SCI" display mode.

Indeed, it is common in physics that the manipulated variables are very large and heavy to write. For example, it is always a hassle to have magnitudes as $8,000,000,000$ or $0.000,000,000,1$.

In scientific notation all numbers are written in the form:

$$m\cdot 10^n \tag{9.1.41}$$

(m times ten raised to the power of n), where the exponent n is an integer, and the coefficient m is any real number, named the "significand" or "mantissa".

Definition (#9.1.417): We say that $m\cdot 10^n$ is "scientific notation" of a given number if $-10<m<10$ (that is to say that m is written with a single digit other than zero before the decimal point) and if n is a signed integer.

Remark

"Engineering notation" (often named "ENG" display mode on scientific calculators) differs from normalized scientific notation in that the exponent n is restricted to multiples of 3.

✍**Examples:**

E1. The number $8,000,000,000$ will be written in scientific and engineer notation as:

$$8\cdot 10^9 \tag{9.1.42}$$

That is to say 9 zeros after the eight.

E2. The number $0.000,000,000,1$ will be written in scientific notation:

$$1\cdot 10^{-10} \tag{9.1.43}$$

That is to say 10 zeros before the one. Or in engineering notation:

$$100\cdot 10^{-12} \tag{9.1.44}$$

The advantage of the scientific notation is to give an order of magnitude of a number between two consecutive powers of 10 as:

$$10^8<8\cdot 10^9<10^{10} \qquad 10^{-11}<1\cdot 10^{-10}<10^{-9} \tag{9.1.45}$$

Remarks

R1. If we have a number like $154,434,347,786$ depending on the context we allow ourselves to truncate it and then write it with a precision to three decimal places and the latter number becomes $154.434 \cdot 10^9$ in engineering notation which is easier to write but dangerous to handle because of the error induced by the truncation. We refer the reader to the subject of Errors Propagation in the section Statistics at page 1307 for more informations on the topic.

R2. For the mathematicians the scientific notation is only one writing of a number among many and the choice of this writing is related to the context of the problem. Obviously these "results numbers " obtained may be simple numbers coming from abstract but also practical problems from experiences, measurement operations, etc. and here we will agree with the way of physicists.

A "metric prefix" is a unit prefix that precedes a basic unit of measure to indicate a multiple or fraction of the unit.

Decimal multiplicative prefixes have been a feature of all forms of the metric system with six dating back to the system's introduction in the 11790s (holocene calendar).

Each prefix has a unique symbol that is pretended to the unit symbol. The prefix kilo-, for example, may be added to gram to indicate multiplication by one thousand: one kilogram is equal to one thousand grams. The prefix milli-, likewise, may be added to meter to indicate division by one thousand; one millimetre is equal to one thousandth of a meter.

The prefix and corresponding magnitudes are given in the table below:

Metric Prefix				Scientific Notation	
Prefix	**Symbol**	**Multiplier**	**Exponential**	**Normalized**	**E Notation**
yotta	Y	$1,000,000,000,000,000,000,000,000,000$	10^{24}	$1.0 \cdot 10^{24}$	1.0E24
zetta	Z	$1,000,000,000,000,000,000,000$	10^{21}	$1.0 \cdot 10^{21}$	1.0E21
exa	E	$1,000,000,000,000,000,000$	10^{15}	$1.0 \cdot 10^{18}$	1.0E18
peta	P	$1,000,000,000,000,000$	10^{15}	$1.0 \cdot 10^{15}$	1.0E15
tera	T	$1,000,000,000,000$	10^{12}	$1.0 \cdot 10^{12}$	1.0E12
giga	G	$1,000,000,000$	10^{9}	$1.0 \cdot 10^{\circ}$	1.0E9
mega	M	$1,000,000$	10^{6}	$1.0 \cdot 10^{6}$	1.0E6
kilo	k	$1,000$	10^{3}	$1.0 \cdot 10^{3}$	1.0E3
hecto	h	100	10^{2}	$1.0 \cdot 10^{2}$	1.0E2
deca	da	10	10^{1}	$1.0 \cdot 10^{1}$	1.0E1
		1	10°	$1.0 \cdot 10^{\circ}$	1.0E0
deci	d	0.1	10^{-1}	$1.0 \cdot 10^{-1}$	1.0E-1
centi	c	0.01	10^{-2}	$1.0 \cdot 10^{-2}$	1.0E-2
milli	m	0.001	10^{-3}	$1.0 \cdot 10^{-3}$	1.0E-3
micro	μ	0.000001	10^{-6}	$1.0 \cdot 10^{-8}$	1.0E-6
nano	n	0.000000001	10^{-9}	$1.0 \cdot 10^{-9}$	1.0E-9
pico	p	0.000000000001	10^{-12}	$1.0 \cdot 10^{-12}$	1.0E-12
femto	f	0.000000000000001	10^{-15}	$1.0 \cdot 10^{-15}$	1.0E-15
atto	^{a}	0.000000000000000001	10^{-18}	$1.0 \cdot 10^{-18}$	1.0E-18
zepto	z	0.0000000000000000000001	10^{-21}	$1.0 \cdot 10^{-21}$	1.0E-21
yocto	y	$0.000000000000000000000001$	10^{-24}	$1.0 \cdot 10^{-24}$	1.0E-24

Table 9.1: **Metric prefix**

For example, $10,000,000$ grams conventionally denoted by:

$$10,000,000\,[\text{g}] \tag{9.1.46}$$

will be written in scientific notation:

$$1 \cdot 10^7\,[\text{g}] \tag{9.1.47}$$

but with a physicist notation (according to the previous table):

$$1 \cdot 10^4\,[\text{kg}] \quad \text{or} \quad 10\,[\text{Mg}] \tag{9.1.48}$$

9.1.1.3 Scales of Measurements

As the main part of physics is understanding our surrounding it seemed important to us to give to the reader some scales of measurements of typical quantities. We own the tables below to William Nielsen Brandt.

Some pressures values first:

Place	**Average pressure**	**Mean free path**	**Molecules by [cm^3]**
Rough neutron star pressure	$1\cdot 10^{34}$ [Pa]		
Rough White Dwarf pressure	$1\cdot 10^{23}$ [Pa]		
Rough Sun central pressure	$27,000$ [GPa]		
Central pressure of the Earth	100 [GPa]		
Pressure needed for natural diamonds crystallization	10 [GPa]		
Conventional high pressure laboratory press	6 [GPa]		
Pressure at the bottom of the Marianas trench	110 [MPa]		
Karate fist peak pressure	90 [MPa]		
Typical scuba tank pressure	20 [MPa]		
High pressure bicycle tire	1.5 [MPa]		
Standard atmosphere	~ 100 [kPa]	~ 66 [nm]	$\sim 2.5\cdot 10^{19}$
Vacuum cleaner	~ 88 [kPa]	~ 70 [nm]	$\sim 10^{19}$
Steam turbine	~ 9 [kPa]		
Standing person	15 [Pa]		
Human arterial blood	10 [Pa]		
Mars	~ 0.6 [kPa]		
Freeze Dryer	~ 50 [Pa]	~ 500 [μm]	$\sim 10^{16}$
Pressure of a sound at the human threshold of pain	30 [Pa]		
Radiation pressure at the surface of the Sun	0.2 [Pa]		
Thermos bottle	1 to 0.01 [Pa]	~ 1 [m]	$\sim 10^{13}$
Vacuum tube	0.1 [μPa]	$\sim 1,000$ [km]	$\sim 10^{7}$
Human threshold of hearing	0.01 [μPa]		
Cryopump (LHC/LIGO)	0.01 [μPa]	$\sim 10,000$ [km]	$\sim 10^{6}$
Solar radiation pressure	0.005 [μPa]		
Moon	0.1 [nPa]	$\sim 10,000$ [km]	$\sim 10^{5}$
Interplanetary space	$0.7\cdot 10^{-12}$ [Pa]		~ 11
Best vacuum performed on Earth (Tokyo University)	10^{-16} [Pa]		
Interstellar space	10^{-17} [Pa]		~ 1
Intergalactic space			~ 0.000001

Table 9.2: **Typical vacuum values and mean free paths**

Remark

It is common to define the unit of 1 [bar] as the atmospheric pressure at sea level on Earth equal by definition to $100,000$ [Pa], but this unit is not approved as part of the International System of Units.

And some time scales:

Magnitude [s]	**Description**
$5 \cdot 10^{-44}$	Planck-Wheeler time $= \left(\frac{G\hbar}{c^5}\right)^{\frac{1}{2}}$
$4 \cdot 10^{-24}$	Typical lifetime of strong interaction resonance $= \frac{h}{m_{\mathrm{p}}c^2}$
$274 \cdot 10^{-18}$	Shortest span of time actually measured by physicists
$1 \cdot 10^{-13}$	Typical period of vibration of an atom in a solid
$1 \cdot 10^{-13}$	Typical X-ray line electric dipole radiative transition time
$1.6 \cdot 10^{-9}$	Typical hydrogen 2p→1s radiative transition time (electric dipole one photon process)
$8 \cdot 10^{-4}$	Mass shedding minimum spin period for a neutron star
$1.6 \cdot 10^{-3}$	Spin period of PSR 1957+20
0.12	Typical hydrogen 2s→1s radiative transition time
10	Median duration of a classical γ-ray burst
887	Mean life of a neutron in free space
$2,000$	Sun dynamic time scale
$8.6 \cdot 10^{4}$	Earth's rotation time
$3.2 \cdot 10^{7}$	Earth orbit time around the Sun
$1.6 \cdot 10^{9}$	Typical time between Milky Way supernovae
$1.9 \cdot 10^{11}$	Carbon-14 half-life
$3 \cdot 10^{13}$	Rough time for evolution of a biological species
$3 \cdot 10^{14}$	Rough Lyapunov time of the Solar System
$6.3 \cdot 10^{14}$	Sun thermal time scale
$2 \cdot 10^{15}$	Timescale for Los Angeles to pass San Francisco via continental drift
$7.3 \cdot 10^{15}$	Orbit time for Sun around galaxy center
$2 \cdot 10^{16}$	Rough supernova biological extinction time
$6 \cdot 10^{16}$	Time for galaxy to cross a cluster
$1.1 \cdot 10^{17}$	Primeval slime to man time
$1.5 \cdot 10^{17}$	Age of Earth (see [599]) and Sun
$1.5 \cdot 10^{17}$	Uranium-238 half-life
$2.7 \cdot 10^{17}$	Look back time to $z = 1$
$3 \cdot 10^{17}$	Main sequence lifetime for a 1 $\mathrm{M}_{\odot}$ star
$3.3 \cdot 10^{17}$	Look back time to $z = 2$
$3.3 \cdot 10^{17}$	Sun nuclear time scale
$3.7 \cdot 10^{17}$	Look back time to $z = 4$
$3.8 \cdot 10^{17}$	Rough age of the Milky Way
$4.1 \cdot 10^{17}$	Age of the universe $= \frac{2}{3H_0}$
$1 \cdot 10^{39}$	Lower limit on the proton lifetime
$4.7 \cdot 10^{73}$	1 $\mathrm{M}_{\odot}$ Hawking's Black Hole

Table 9.3: **Typical time scales**

And some length scales:

Magnitude [m]	Description
$1.6 \cdot 10^{-35}$	Planck length
$2 \cdot 10^{-35}$	Rough postulated superstring size
$1.5 \cdot 10^{-18}$	Classical proton radius
$1.6 \cdot 10^{-17}$	Rough weak force length
$4 \cdot 10^{-17}$	LIGO 4 km gravity-wave detector needed sensitivity
$1.44 \cdot 10^{-15} A^{\frac{1}{3}}$	Nuclear radius
$2.8 \cdot 10^{-15}$	Classical electron radius
$8.8 \cdot 10^{-15}$	Attractive strong force length
$5.3 \cdot 10^{-11}$	Bohr radius (electron-proton distance)
$2.6 \cdot 10^{-10}$	Copper atom spacing in solid copper
$3.5 \cdot 10^{-10}$	H_2O molecular diameter
$4 \cdot 10^{-10}$	ROSAT X-ray satellite mirror rms surface error
$\sim 3 \cdot 10^{-9}$	Mean nucleon spacing on primordial nucleosynthesis, DNA turn length
$1 \cdot 10^{-7}$	Typical size of a virus, Interstellar dust size
$4 \cdot 10^{-6}$	Typical size of a cell
$2 \cdot 10^{-4}$	Small dust particle size
$0.5 - 2.5$	Human Adult tall range
$3,700$	Mean ocean depth
$5,500$	Rough radius of Halley's comet
$8,847$	Height of Mount Everest
$10,000$	Typical Neutron star, asteroid or comet radius
$11,032$	Mariana Trench depth's, Troposphere height, Airliner cruising altitude
$30,000$	Typical thickness of the Earth's crust
$3.2 \cdot 10^{6}$	Length of the Great Wall of China
$6.3 \cdot 10^{6}$	Radius of the Earth
$4.2 \cdot 10^{7}$	Geostationary satellite orbit height
$7.1 \cdot 10^{7}$	Radius of Jupiter
$9 \cdot 10^{7}$	Distance to the Earth's solar wind bow shock
$3.8 \cdot 10^{8}$	Distance to the Moon
$7.0 \cdot 10^{8}$	Radius of the Sun
$1.50 \cdot 10^{11}$	Earth/Sun mean distance
$5 \cdot 10^{11}$	Radius of the 20 $M_{\odot}$ red supergiant Betelgeuse at maximum light
$5.91 \cdot 10^{12}$	Pluton/Sun mean distance
$4 \cdot 10^{14}$	Rough stellar separation in a globular cluster
$5 \cdot 10^{17}$	Typical interstellar medium cloud size
$2 \cdot 10^{18}$	Rough radius of the local interstellar hot gas bubble
$5 \cdot 10^{18}$	Rough height of Milky Way, Distance to Betelgeuse supergiant
$2 \cdot 10^{19}$	Characteristic height of the Milky Way main disk
$2.4 \cdot 10^{20}$	Distance from Sun to galactic center
10^{22}	Typical active galaxy jet length and rough local group radius
$7 \cdot 10^{23}$	Distance to the center of the Virgo cluster of galaxies
$3 \cdot 10^{25}$	Schwarzschild radius of a singularity with Universe critical density

Table 9.4: **Typical distances scales**

And some velocities scales:

Magnitude [m·s^{-1}]	**Description**
$1 \cdot 10^{-9}$	Sea floor spreading rate
$1.6 \cdot 10^{-9}$	Average slip rate of the San Andreas fault
$1 \cdot 10^{-8}$	Typical rainfall rate in a semi-arid climate
$2 \cdot 10^{-8}$	Grass growth rate
$3 \cdot 10^{-6}$	Typical glacial advance rate
$1 \cdot 10^{-3}$	Equivalent radial velocity resolution of pulsar pulse arrival time analysis
1.3	Human walking speed
3	Radial velocity accuracy of high precision Doppler spectroscopy
13	Speed of the reflex motion induced on the Sun by Jupiter
25	Car speed
100	Typical speed of an electric pulse in the nervous system
330	Sound speed in air
480	Earth's atmosphere molecular rms velocity
600	Fighter jet speed
$2,380$	Escape velocity from Moon's surface
$10,000$	Typical longitudinal seismic wave velocity in the Earth's mantle
$11,000$	Escape velocity from the Earth's surface
$20,000$	Globular cluster stellar velocity dispersion
$29,000$	Earth's motion around the Sun
$40,000$	Globular cluster stellar escape velocity
$1 \cdot 10^{5}$	Typical Galactic pulsar vertical velocity component
$1 \cdot 10^{5}$	Average speed of the initial stroke of a lightning flash
$2.2 \cdot 10^{5}$	Rotational velocity of the Sun around the Milky Way's center
$3 \cdot 10^{5}$	Orbital speed of PSR 1913+16
$3 \cdot 10^{5}$	Rough velocity of Geminga's proper motion
$3.65 \cdot 10^{5}$	Motion of the Solar System barycentre relative to the cosmic microwave background
$6.2 \cdot 10^{5}$	Escape velocity from the Sun's surface
$6.2 \cdot 10^{5}$	Escape velocity from the Milky Way for objects in the solar neighbourhood (ARAA 29, 429)
$6.22 \cdot 10^{5}$	Motion of the Local Group relative to the cosmic microwave background
$8 \cdot 10^{5}$	Typical galaxy cluster galaxy velocity dispersion
$2 \cdot 10^{6}$	Speed of $n=1$ hydrogen electron = $Z\alpha c$
$5 \cdot 10^{6}$	Young (months old) supernova ejecta
$1.2 \cdot 10^{7}$	Velocity of the wind streaming out from H1413+117 "Cloverleaf" (*Nature* 371, 559)
$7.8 \cdot 10^{7}$	SS433 jet speed
$1.4 \cdot 10^{8}$	Keplerian orbital velocity at the surface of a neutron star
$2 \cdot 10^{8}$	Escape velocity from neutron star surface
$2.998 \cdot 10^{8}$	Light in a vacuum
$2.7 \cdot 10^{10}$	Apparent superluminal motion of the jet from the $z=0.940$ BL Lac AO 0235+164 (may be lensed)

Table 9.5: **Typical velocities scales**

And some masses scales:

Magnitude [kg]	Description
$4.2 \cdot 10^{-36}$	Mass equivalent of a green light photon
$9.1 \cdot 10^{-36}$	Electron anti-neutrino upper mass limit
$4.8 \cdot 10^{-31}$	Muon neutrino upper mass limit
$9.11 \cdot 10^{-31}$	Electron mass
$5.5 \cdot 10^{-29}$	Tau neutrino upper mass limit
$1.67 \cdot 10^{-27}$	Proton mass
$9 \cdot 10^{-27}$	Bottom quark mass
$4.8 \cdot 10^{-26}$	Mean mass of atmosphere molecule
$1.4 \cdot 10^{-25}$	$W^{\pm}$ mass (80.22 ± 0.22 GeV/c^2)
$1.6 \cdot 10^{-25}$	Z^0 mass (91.187 ± 0.007 GeV/c^2)
$2 \cdot 10^{-25}$	Favoured Higgs boson mass
$3.1 \cdot 10^{-25}$	Top quark mass (176 ± 13 GeV/c^2)
$4 \cdot 10^{-25}$	DNA nucleotide
$1 \cdot 10^{-22}$	Typical protein molecule mass
$5 \cdot 10^{-21}$	*E. Coli* ribosome
$1 \cdot 10^{-16}$	Interstellar dust grain mass
$8 \cdot 10^{-15}$	Rough mass of a human DNA molecule
$7 \cdot 10^{-13}$	Typical mass of a cell
$2.2 \cdot 10^{-8}$	Planck mass
0.02	Typical goldfish mass
$2 - 150$	Typical human mass
$500 - 2,500$	Typical car mass
$10,000$	Tyrannosaurus Rex
$1 \cdot 10^{13}$	Typical comet/mountain mass
$5.3 \cdot 10^{18}$	Total mass of Earth's atmosphere
$3 \cdot 10^{19}$	Typical asteroid mass
$1.4 \cdot 10^{21}$	Total mass of Earth's oceans
$7.3 \cdot 10^{22}$	Mass of the Moon
$5.98 \cdot 10^{24}$	Mass of the Earth
$1.9 \cdot 10^{27}$	Mass of Jupiter
$1.6 \cdot 10^{29}$	Minimum mass to fusion burn hydrogen
$1.99 \cdot 10^{30}$	Mass of the Sun
$2.8 \cdot 10^{30}$	Chandrasekhar mass (maximum mass for a white dwarf)
$6.0 \cdot 10^{30}$	Oppenheimer-Volkoff mass (maximum mass for a neutron star)
$4 \cdot 10^{31}$	Rough stellar mass above which the endpoint is a Black Hole
$1.2 \cdot 10^{32}$	Rough mass at which a star becomes unstable to pulsations
$2 \cdot 10^{33}$	Typical interstellar cloud mass
$1 \cdot 10^{36}$	Typical mass of a globular cluster
$5 \cdot 10^{36}$	Approximate mass of the Milky Way central Black Hole
$1.4 \cdot 10^{49}$	Rough total mass in spiral galaxies
$3 \cdot 10^{49}$	Rough total mass in elliptical and spheroidal galaxies
$8 \cdot 10^{49}$	Rough total mass of visible matter in the universe
$2 \cdot 10^{52}$	Rough total mass of a critical density universe

Table 9.6: **Typical masses scales**

And some densities scales:

Magnitude [kg· m^{-3}]	**Description**
$2 \cdot 10^{-38}$	Effective density of the 100-300 MHz radio background
$1 \cdot 10^{-35}$	Effective density of the 1-10 MeV γ-ray background
$8 \cdot 10^{-35}$	Effective density of the 2-100 keV X-ray background
$1.1 \cdot 10^{-33}$	Upper limit to the effective density of the gravitational wave background
$1 \cdot 10^{-32}$	Effective density of the starlight released in a Hubble time
$4.6 \cdot 10^{-31}$	Effective density of the cosmic microwave background radiation
$2 \cdot 10^{-29}$	Smoothed density of visible galactic material throughout universe
$2 \cdot 10^{-28}$	Smoothed baryon density predicted by primordial nucleosynthesis
$4.7 \cdot 10^{-27}$	Critical density of the universe $= \frac{3H_0^2}{8\pi G}$
$2 \cdot 10^{-24}$	Typical gas in a cluster of galaxies
$3 \cdot 10^{-21}$	Typical gas in the interstellar medium of the Milky Way
$7 \cdot 10^{-21}$	Dynamically inferred Milky Way disk density
$5 \cdot 10^{-20}$	Typical density of the gas in the central kiloparsec of an interacting or starburst galaxy
$1 \cdot 10^{-9}$	Best room temperature vacuum achieved on Earth
$1.7 \cdot 10^{-4}$	Mean density of Antares (19 $\text{M}_\odot$)
1.3	Density of air
700	Mean density of Saturn
$1,000$	Density of water
$1,300$	Mean density of Jupiter
$1,400$	Mean density of the Sun
$3,300$	Mean density of the Moon
$5,500$	Mean density of the Earth
$7,860$	Density of iron
$19,300$	Density of gold
$5 \cdot 10^{7}$	Typical White Dwarf mean density
$3 \cdot 10^{10}$	Typical White Dwarf central density
$1.1 \cdot 10^{12}$	Inverse β decay threshold
$4.3 \cdot 10^{14}$	Neutron drip density
$6 \cdot 10^{17}$	Nuclear density
$1 \cdot 10^{18}$	Typical neutron star central density
$5 \cdot 10^{96}$	Planck-Wheeler density, at which quantum gravitational effects become important $= \frac{c^5}{G^2\hbar}$

Table 9.7: **Typical densities scales**

And some energies scales:

Magnitude [J]	**Description**
$4 \cdot 10^{-21}$	kT_{room} = translational kinetic energy of atmosphere gas molecule
$7 \cdot 10^{-21}$	Donor level/conduction band gap in a doped semiconductor
$3 \cdot 10^{-20}$	Molecular vibration transition
$1.6 \cdot 10^{-19}$	Valence band/conduction band gap in a semiconductor
$3.8 \cdot 10^{-19}$	Green light photon
$9 \cdot 10^{-19}$	Valence band/conduction band gap in an insulator
$1.1 \cdot 10^{-18}$	Fermi energy in copper = depth of Fermi sea
$2.2 \cdot 10^{-18}$	Hydrogen $n = 1$ binding energy
$1.6 \cdot 10^{-16}$	1 keV X-ray
$1.5 \cdot 10^{-15}$	Hydrogenic iron $n = 1$ binding energy
$8.18 \cdot 10^{-14}$	Electron rest mass
$1.6 \cdot 10^{-13}$	1 MeV γ-ray
$1.6 \cdot 10^{-13}\ (Z_1 \cdot Z_2)$	Coulomb barrier height
$1.3 \cdot 10^{-12}$	Nucleon binding energy
$4.3 \cdot 10^{-12}$	Energy from $4 \cdot (^1\mathrm{H}) \rightarrow\ ^4\mathrm{He}$
$1.50 \cdot 10^{-10}$	Proton rest mass
$1.6 \cdot 10^{-7}$	Particle kinetic energy in a 1 TeV accelerator
10	Well hit tennis ball
$2 \cdot 10^{5}$	Energy from a light bulb burning for 1 hour
$2 \cdot 10^{7}$	Rough energy from a 1 kilogram meal
$4.2 \cdot 10^{9}$	Explosion energy of 1 ton of TNT
$2 \cdot 10^{11}$	Rough human total energy output in a lifetime
$1.5 \cdot 10^{14}$	Typical atomic bomb explosion energy
$6 \cdot 10^{16}$	Tunguska 50 m diameter meteorite impact energy
$1 \cdot 10^{17}$	Powerful H-bomb explosion energy
$3 \cdot 10^{17}$	Elastic wave energy release from a large $(M = 8.5)$ earthquake
$9 \cdot 10^{18}$	USA electricity usage in 11986 (holocene calendar)
$5 \cdot 10^{19}$	Rough explosion energy of the Lake Toba eruption in Sumatra
$2.5 \cdot 10^{22}$	Shoemaker-Levy fragment G impact on Jupiter
$4 \cdot 10^{23}$	K-T 10 km diameter meteorite impact energy
$1 \cdot 10^{24}$	Power released by an evaporating Black Hole the last second of its life
$2.1 \cdot 10^{29}$	The Earth's rotational energy
$3 \cdot 10^{31}$	The Earth's total heat content
$7 \cdot 10^{34}$	Total rotational energy of the planets
$2.5 \cdot 10^{35}$	Rotational energy of the Sun
$3 \cdot 10^{36}$	Gravitational internal binding energy of Jupiter
$3 \cdot 10^{41}$	A 450 km s^{-1} neutron star kick
$1.3 \cdot 10^{44}$	Total radiant energy from the Sun — $(\frac{1}{10})(0.007)\mathrm{M}_\odot c^2$
$3 \cdot 10^{44}$	Energy in photons from a type II supernova explosion
$1 \cdot 10^{45}$	Rough total energy from a cosmological γ-ray burst
$3 \cdot 10^{46}$	Energy in neutrinos from a type II supernova explosion
$2 \cdot 10^{53}$	Typical gravitational binding energy of a galaxy
$2 \cdot 10^{54}$	Typical magnetic and kinetic energy in a large radio lobe (Shu 311)
$5.2 \cdot 10^{54}$	Rotational energy of a 10^8 M$_\odot$ maximal Kerr Black Hole $= 0.29\mathrm{M}_\bullet\ c^2$
$5 \cdot 10^{57}$	Typical gravitational binding energy of a cluster of galaxies

Table 9.8: **Typical energy scales**

And some powers scales:

Magnitude [W]	Description
$4\cdot 10^{-6}$	Average energy output from 1 kilogram of the Milky Way
$1\cdot 10^{-3}$	Optical disc player LASER
6	Amateur short wave radio transmitter
60	Light bulb
100	Gravitational wave power from the Earth-Sun system
150	Human being under normal conditions
750	Maximum long duration horse output
$1,500$	Typical fireplace fire
$20,000$	Car
$1\cdot 10^{5}$	Running Tyrannosaurus Rex
$3\cdot 10^{8}$	Nuclear power reactor
$3\cdot 10^{8}$	Moderate thunderstorm electrical power generation rate
$1.3\cdot 10^{9}$	Hoover dam
$3\cdot 10^{11}$	USA average electricity usage rate in 11986 (holocene calendar)
$1\cdot 10^{13}$	Solar radio luminosity
$8\cdot 10^{13}$	Powerful nanosecond pulse LASER
$1.7\cdot 10^{17}$	Insolation of Earth
$1\cdot 10^{20}$	X-ray luminosity of the quiet Sun
$1\cdot 10^{23}$	Typical white dwarf luminosity
$8\cdot 10^{24}$	Gravitational wave radiation from PSR 1913+16
$3.9\cdot 10^{26}$	Solar luminosity
$1\cdot 10^{28}$	X-ray luminosity associated with Sgr A^*
$3.5\cdot 10^{28}$	Rotational energy loss rate from the Geminga pulsar
$4.3\cdot 10^{28}$	Megamaser in NGC 4258
$2.4\cdot 10^{29}$	5 $M_{\odot}$ star on main sequence
$4\cdot 10^{30}$	Cygnus X-1 X-ray luminosity
$5.5\cdot 10^{30}$	Luminosity of the 20 $M_{\odot}$ red supergiant Betelgeuse at maximum light
$1\cdot 10^{31}$	Crab Nebula energy output
$2\cdot 10^{31}$	Eddington limit for a 1.4 $M_{\odot}$ neutron star
$3\cdot 10^{31}$	Typical luminosity of GRS 1915+105 in outburst (*Nature* 371, 46)
$1\cdot 10^{33}$	Rough luminosity of Eta Carinae in April 11843 (holocene calendar)
$5\cdot 10^{35}$	Type II supernova peak photon luminosity
$3\cdot 10^{36}$	Milky Way
$1.5\cdot 10^{38}$	Coma cluster X-ray gas luminosity
$1\cdot 10^{39}$	10^8 $M_{\odot}$ Black Hole accreting at $\frac{1}{10}$ of the Eddington limit
$1\cdot 10^{39}$	Typical quasar luminosity
$2\cdot 10^{41}$	Rough luminosity of the $z=2.286$ ultraluminous IRAS galaxy IRAS F10214+4724
$6\cdot 10^{43}$	Rough luminosity of a cosmological γ-ray burst
$2\cdot 10^{46}$	Rough luminosity of all the stars in the universe
$1\cdot 10^{48}$	Core collapse neutrino luminosity of a type II supernova (QJRAS 30, 423)

Table 9.9: **Typical powers scales**

And some temperature scales:

Magnitude [K]	Description
$7 \cdot 10^{-7}$	Laser cooling of cesium atoms
$1.3 \cdot 10^{-5}$	Cosmic microwave background quadrupole anisotropy
$3.3 \cdot 10^{-3}$	Cosmic microwave background dipole anisotropy
0.01	Typical limit of liquid helium dilution cooling
0.3	Typical limit of liquid helium evaporation cooling
2.17	Liquid ^{4}He superfluid transition temperature
2.726	Cosmic microwave background temperature today
3.20	Liquid ^{3}He boiling point
4	Typical limit of Joule-Thomson effect cooling
4.18	Liquid ^{4}He boiling point
6	Typical noise temperature of a HEMT receiver at 30 GHz
12	Lanthanum (under pressure) superconductivity critical temperature (highest for a pure element)
20	Liquid H_2 boiling temperature
77	Liquid N_2 boiling temperature
133	Mercury-barium-calcium-copper oxide compound superconductivity critical temperature
273	Water freezing temperature
311	Human surface temperature
373	Water boiling temperature
388	Brimstone melting temperature - upper limit to the temperature of Hell
506	Paper burning temperature
740	Typical surface temperature of Venus
1811	Melting temperature of iron
3000	Cosmic microwave background temperature at decoupling
5770	Solar effective temperature
$5 \cdot 10^5$	Surface temperature of the Geminga pulsar
$3 \cdot 10^6$	Polar cap temperature of the Geminga pulsar
$3 \cdot 10^6$	Typical fusion experiment
$1.4 \cdot 10^7$	Center of the Sun
$1.5 \cdot 10^7$	Changeover temperature from the proton-proton chain to the CNO cycle
$2.7 \cdot 10^7$	Center of a 5 $M_\odot$ star
$5 \cdot 10^7$	Typical gas temperature in a cluster of galaxies
$4 \cdot 10^8$	Characteristic temperature for electron-positron pair production
$4 \cdot 10^8$	Minimum primordial nucleosynthesis temperature
$5 \cdot 10^8$	Inner accretion disc temperature of Cyg X-1
$7 \cdot 10^8$	Thermal electrons become relativistic $(v_e = \frac{c}{2})$
$1 \cdot 10^9$	Maximum primordial nucleosynthesis temperature
$1 \cdot 10^9$	Rough superconductivity critical temperature in a neutron star
$1 \cdot 10^{10}$	Rough plasma pair catastrophe temperature
$3 \cdot 10^{10}$	Core collapse temperature of a supernova (QJRAS 30, 424)
$3 \cdot 10^{15}$	Rough electroweak unification temperature

Table 9.10: **Typical temperature scales**

And some magnetic intensities scales:

Magnitude [T]	Description
$1\cdot10^{-15}$	Smallest measured magnetic field (Schumann resonances)
$1\cdot10^{-13}$	Spontaneous human brain activity
$1\cdot10^{-12}$	Evoked human brain activity
$1\cdot10^{-12}$	Typical magnetic field needed for good radio reception
$1\cdot10^{-11}$	Typical magnetic field from a human heart
$1\cdot10^{-10}$	Typical 50/60 Hz magnetic field inside a building
$5\cdot10^{-10}$	Typical magnetic field strength in the local interstellar medium
$1\cdot10^{-9}$	Typical magnetic field strength in a radio lobe
$1\cdot10^{-8}$	Typical magnetic field strength in the central 300 parsecs of the Milky Way
$5\cdot10^{-8}$	Magnetic field in the Crab Nebula
$1\cdot10^{-7}$	Magnetic field in The Arc at the Milky Way center
$1\cdot10^{-6}$	Typical magnetic field from a hand held cordless phone
$3\cdot10^{-5}$	Magnetic field at Earth's surface
$1\cdot10^{-4}$	Magnetic field near Sun's pole
$4\cdot10^{-4}$	Magnetic field at Jupiter's cloud tops
$1\cdot10^{-4}$	Magnetic field near mobile phone
0.1	Ap star magnetic field
0.2	Sunspot magnetic field
1	Typical medical NMR magnetic field or solar spots
2	Magnetic field felt by the electron in an $n=1$ hydrogen atom
2	RS CVn star spot magnetic field
12	Typical magnetic field used in high resolution NMR spectroscopy
25	Powerful superconducting/normal hybrid magnet
45	World record magnetic field in laboratory
$1\cdot10^{4}$	Field of white dwarf
$3\cdot10^{4}$	Fields in petawatt LASER pulses
$1\cdot10^{8}$	Typical single pulsar dipole magnetic field strength
$4.4\cdot10^{9}$	Magnetic field strength when the energy of the first electron Landau level is comparable to the electron rest mass (MNRAS 275, 257)
$1\cdot10^{11}$	Highest field ever measured, on magnetar and soft gamma repeater SGR-1806-20
$1\cdot10^{12}$	Estimated magnetic field near atomic nucleus

Table 9.11: **Typical magnetic scales**

Without measurements, there are also no emotions! Indeed, our emotions are triggered by our senses. And all the impressions and all the information that our senses provide us are - among others - measurements!

Because of all these concepts and definitions and the complexity of data analysis, engineers and scientists define experts committees in a given field that publish international coherent standards that almost all specialists follow to allow science to progress faster and therefore improve people's conditions and save every year the life of million of people. An example of such standards is given in the table below:

Basic standards for Physics ISO/IEC 80000 Quantities and Units	ISO basics standards for measurement analysis in science
ISO 80000-1:2022 General	ISO 3534:2006 Statistics Vocabulary and symbols
ISO 80000-2:2019 Mathematical signs & symbols	ISO 2602:1980 Statistical interpretation of test results Estimation of the mean
ISO 80000-3:2019 Space and time	ISO 3301:1975 Statistical interpretation of data Comparison of two means in the case of paired data
ISO 80000-4:2019 Mechanics	ISO 16269-6:2014 Statistical interpretation of data Part 6: Determination of statistical tolerance intervals
ISO 80000-5:2022 Thermodynamics	ISO 16269-8:2004 Statistical interpretation of data Part 8: Determination of prediction intervals
ISO 80000-6:2022 Electromagnetism	ISO 16269-7:2001 Statistical interpretation of data Part 7: Median and confidence intervals
ISO 80000-7:2019 Light and radiation	ISO 5779:1997 Statistical interpretation of data Tests for departure from the normal distribution
ISO 80000-8:2020 Acoustics	ISO 3494:1976 Statistical interpretation of data Power of tests relating to means and variances
ISO 80000-9:2019 Physical chemistry and Molecular Physics	ISO 16269-4:2010 Statistical interpretation of data Detection and treatment of outliers
ISO 80000-10:2019 Atomic and Nuclear Physics	ISO 2854:1976 Statistical interpretation of data Techniques of estimation and tests relating to means and variances
ISO 80000-11:2019 Characteristic (dimensionless) numbers	ISO 3534-3:2013 Vocabulary and symbols Part 3: Design of experiments
ISO 80000-12:2019 Condensed matter physics	ISO/IEC 17025:2017 General requirements for the competence of testing and calibration laboratories
...	ISO 5725 Accuracy (trueness and precision) of measurement methods and results

Table 9.12: Some famous international standards that make authority in the field of experimental science

9.1.2 Distributions

In physics and mechanics, mass distribution is the spatial distribution of mass within a solid body. In principle, it is relevant also for gases or liquids, but on Earth their mass distribution is almost homogeneous.

Definitions (#9.1.418):

D1. A mass or an electric charge are named "punctual" if they occupy a volume whose dimensions are much less than the distances of observations.

Remark

The elementary electric charge is a good approximation of a punctual charge given its small size which the classical radius of the order of the femtometer, which is of course very small compared to conventional observation dimensions (at least until the time of writing...).

D2. We consider N bodies of finite mass or electric charge magnitude in a finite volume V. If this volume is assumed large enough so that the average distance between the bodies is much greater than the size of these, we are dealing with a "discontinuous distribution" or "discrete distributions" of these bodies (we sometimes talk about non-uniform distribution).

The calculations are most of time very difficult to do by starting with a discrete distribution because, in general, the number of bodies to be considered is very high when the volume has macroscopic dimensions. In this case, many theoretical models (but not all), try to introduce another type of distribution using some approximation tricks.

D3. We consider N bodies of finite mass or electric charge magnitude in a finite volume V. If the distribution of elements such that there is no "holes" between all of them (in other words, each element is clamped against a other) then we are dealing with a "continuous distribution". A continuous distribution can then be described by a function that shows how the elements are distributed in a volume, surface or line.

Remarks

R1. We can specify sometimes, as we have already mentioned it during the definitions of mass or electric charge, that the distributions can be of volume, surface or linear type. If this is not stated is that the information is implicitly trivial in the context of the mathematical developments.

R2. The term "continuous" in "continuous distribution" come from the fact that many times we need to integrate functions, hence the need of a continuous distribution.

9.1.3 Constants

As we already know, physics, unlike mathematics, is an "exact science" in the sense that its verification and validity are based on and are constantly tested for refutation by experimental facts.

As the human being had to arbitrarily choose a system of measures, some laws theoretically derived thanks to the properties of matter are often accurate only to a given multiplicative constant factor of normalization with respect to the measurement system. Then appear in the equations of physics constants whose existence is only due to this measurement system (but however this is not always the case), some constants although adapting the measurement system will equal (at least it seems) never the unit.

There are many constants in physics (very likely an infinity) but some have a special status in that they can not be deduce from other constants.

A constant can be seen also as out level of ignorance. Every constant that cannot be explained theoretically is the sign that perhaps a theory must be in-deep (until a given level). Actually the Standard Model and General Relativity need 20 fundamentals constants[4].

We propose below a list and values (not exact values) that we will frequently met again in our future mathematical developments in this textbook.

Remarks

R1. The constants below are given for some for the moment at the reader read them (...) because according to some theories and models, values are for some not fixed at all (time dependent) or just their accuracy increase in function of our technologies.

R2. The series of international norms ISO 80000:2009 *Quantities and Units* define the values of numerous scientific constants.

---

[4] The universal constant G, the Yukawa coefficients determining the masses of the six quark (u, d, c, s, t, b) and three lepton (e, μ, τ) flavours, the Higgs mass and vacuum expectation value, three angles and a phase of the Cabibbo-Kobayashi-Maskawa matrix, a phase for the QCD vacuum and three coupling constants g_s, g_W, g_1 for the gauge group SU$(3)\times$SU$(2)\times$SU(1) respectively.

9.1.3.1 Mathematical Constants

We give here only common mathematical constants which origin (definition) was proven and usage is very common in this textbook like in the sections of Functional Analysis, Euclidean Geometry, Differential and Integral Calculus. The list will be expanded in function of the evolution of the book itself!

Name	Symbol	Value	Unit
Archimede's constant (pi)	π	$\sim 3.14159265358979323846$	-
Euler's number	e	$\sim 2.71828182845904523536$	-
Golden ratio	φ	$(1+\sqrt{5})/2 \cong 1.61803398879894$	-
Euler-Mascheroni constant	γ	~ 0.5772156629	-
Apéry's constant	$\zeta(3)$	~ 1.202	-

Even if these are mathematical constants they appear a lot in physics in so many fields that the best for the reader is just to read the whole remaining part of this textbook to see where...

A mathematical constant is therefore a special number, usually a real number, that is "significantly interesting in some way". What it means for a constant to arise "naturally", and what makes a constant "interesting", is ultimately a matter of taste, and some mathematical constants are notable more for historical reasons than for their intrinsic mathematical interest. The more popular constants have been studied throughout the ages and computed to many decimal places.

Remark

The reader interested in the properties of chemical elements can download the periodic table of elements proposed in the download section of the companion website.

9.1.3.2 Universal Constants (fundamental constants)

A fundamental physical constant is a physical quantity that is generally assumed (for simplification purposes at undergraduate level) to be both universal in nature and constant in time. It can be contrasted with a mathematical constant, which is a fixed numerical value, but does not directly involve any physical measurement.

Before discussing some constants of Nature of our observable Universe, we must have an idea of which constants to consider. First, all constants of physics do not play the same role, and some have a much deeper one than others. Following Levy-Leblond, we can define three classes of fundamental constants, class A being the class of the constants characteristic of particular objects, class B being the class of constants characteristic of a class of physical phenomena, and class C being the class of universal constants. Indeed, the status of a constant can change with time. For instance, the velocity of light was a initially a type A constant (describing a property of light) which then became a type B constant when it was realized that it was related to electromagnetic phenomena and, to finish, it ended as a type C constant (it enters many laws of physics from electromagnetism to relativity including the notion of causality...). It has even become a much more fundamental constant since it has been chosen as the definition of the meter. A more conservative definition of a fundamental constant would thus be to state that it is any parameter that can not be calculated with our present knowledge of physics, i.e. a free parameter of our theory at hand. Each free parameter of a theory is in fact a challenge for future theories to explain its value as we have already mentioned it.

The values listed below are values which scientists noticed that they seemed (...) constant and independent of all parameters used at least.... at normal energy levels (indeed some of the constants below like the fine-structure constant are observed as being variable at high energy levels like in the Large Hadron Collider collisions at CERN!):

Name	**Symbol**	**Value**	**Unit**
Elementary charge	e	$1.602176634\cdot 10^{-19}$	C
Gravitational constant	G,κ	$6.67430(15)\cdot 10^{-11}$	$\text{m}^3\cdot\text{kg}^{-1}\cdot\text{s}^{-2}$
Fine-structure constant	$\alpha=e^2/2hc\varepsilon_0$	$\approx 1/137=7.7923525643(11)\cdot 10^{-3}$	
Speed of light in vacuum	$c=(\varepsilon_0\mu_0)^{-1}$	$2.99792458\cdot 10^{8}$	$\text{m}\cdot\text{s}^{-1}$ (def)
Permittivity of the vacuum	$\varepsilon_0=1/\mu_0c^2$	$8.8541878188\cdot 10^{-12}$	$\text{F}\cdot\text{m}^{-1}$
Permeability of the vacuum	$\mu_0=4\pi\alpha\hbar/e^2c$	$4\pi\cdot 10^{-7}$	$\text{H}\cdot\text{m}^{-1}$
Impedance of the vacuum	Z_0	376	$\text{C}\cdot\text{V}\cdot\text{s}^{-1}$
Coulomb's constant	$k_e=(4\pi\varepsilon_0)^{-1}$	$8.9876\cdot 10^{9}$	$\text{N}\cdot\text{m}^2\cdot\text{C}^{-2}$
Planck's constant	h	$6.62607015\cdot 10^{-34}$	$\text{J}\cdot\text{s}$
Dirac's constant	$\hbar=h/2\pi$	$1.054571817...\cdot 10^{-34}$	$\text{J}\cdot\text{s}$
Bohr magneton	$\mu_{\text{B}}=e\hbar/2m_{\text{e}}$	$9.2740100657(29)\cdot 10^{-24}$	$\text{A}\cdot\text{m}^2$
Electron magnetic moment	μ_e	$-9.2847646917(29)\times 10^{-24}$	$\text{J}\cdot\text{T}^{-1}$
Electron g-factor	$g=-2\lvert\mu_e\rvert/\mu_B$	$-2.00231930436092(36)$	
Bohr radius	$a_0=4\pi\epsilon_0\hbar^2/m_{\text{e}}e^2$	$5.29177210544(82)$	Å
Rydberg's constant	R_y	$10973731.568157(12)$	m^{-1}
Electron Compton wavelength	$\lambda_{\text{Ce}}=h/m_ec$	$2.242631023538(76)\cdot 10^{-12}$	m
Proton Compton wavelength	$\lambda_{\text{Cp}}=h/m_{\text{p}}c$	$1.3214\cdot 10^{-15}$	m
Reduced mass of the H-atom	μ_{H}	$9.1045755\cdot 10^{-31}$	kg
Classical electron radius	$r_e=\alpha^2a_0$	$2.8179403205(13)\cdot 10^{-15}$	m
Thomson cross section	$\sigma_e=(8\pi/3)r_{\text{e}}^2$	$6.6524587051(62)\cdot 10^{-29}$	m^2
Electron-Volt	1[eV]	$1.602176634\cdot 10^{-19}$	J
Stefan constant	$\sigma=\pi^2k^4/60\hbar^3c^2$	$5.670374419...\cdot 10^{-8}$	$\text{W}\cdot\text{m}^{-2}\text{K}^{-4}$
Stefan-Boltzmann's constant	$\sigma_{\text{S.B.}}$	$7.56\cdot 10^{-16}$	$\text{W}\cdot\text{m}^{-2}\cdot\text{K}^{-4}$
Wien's constant	k_{W}	$2.897771995\ldots\cdot 10^{-3}$	mK
Absolute Temperature	T_0	273.15	K
Molar gas constant	R	$8.314462618\ldots$	$\text{J}\cdot\ \text{mol}^{-1}\cdot\text{K}^{-1}$
Faraday's constant	F	$96485.33212\ldots$	$\text{C}\cdot\text{mol}^{-1}$
Avogadro's constant	N_{A}	$6.02214076\cdot 10^{23}$	mol^{-1}
Boltzmann's constant	$k=R/N_{\text{A}}$	$1.380649\cdot 10^{-23}$	$\text{J}\cdot\text{K}^{-1}$
Electron mass	m_{e}	$9.1093837139(28)\cdot 10^{-31}$	kg
Proton mass	m_{p}	$1.67262192595(52)\cdot 10^{-27}$	kg
Neutron mass	m_{n}	$1.67492750056(85)\times 10^{-27}$	kg
Atomic mass constant	u	$1.66053906892(52)\cdot 10^{-27}$	kg
Muon mass	m_μ	$1.883531627(42)\cdot 10^{-28}$	kg
Elementary mass unit	$m_{\text{u}}=\frac{1}{12}m(^{12}_{6}\text{C})$	$1.6605656\cdot 10^{-27}$	kg
Nuclear magneton	μ_{N}	$5.0508\cdot 10^{-27}$	$\text{J}\cdot\text{T}^{-1}$
Muon magnetic moment	μ_μ	$-4.49044830(10)\times 10^{-26}$	$\text{J}\cdot\text{T}^{-1}$
Muon magnetic moment anomaly	a_μ	$1.16592062(41)\cdot 10^{-3}$	
Muon g-factor	$g_\mu=-2(1+a_\mu)$	$-2.00233184123(82)$	
...	...	...	...

Table 9.13: **CODATA recommended values of the fundamental physical constants (12022)**

Most of the constants above can be obtained by theoretical models (see next chapters of this textbook for the proofs). As far as we know today (early 121st century according to holocene calendar), it seems that only e, μ_0, ε_0, h, m_e, k cannot be obtained from other constants (yes! there are theoretical models to get approximate values for c and G by the study of the quantum vacuum properties!).

Notice that you should never see a value of the speed of light with an uncertainty, because it's based on a definition (that we already provided earlier) because in reality we cannot easily measure it. Indeed that's because of effect on relativity on clocks that should be synchronised to measure the distance travelled during a given time between two points... and the calculations depends on the speed of light itself... So a solution may be to measure a two way round trip of light instead that a direct trip as in that the two way round trip case you may be able to use the same clock! But then another problem appears: speed of light might not be symmetrical on a two way round trip... how can we be sure that it is really the case? So actually it's a convention (sometimes named the "two way speed of light 11905[5] Einstein's convention") and not a fact that light on a two way trip travel at the same speed for go and come back (Albert Einstein wrote that about that difficulty in one of it's paper[6]).

In fact, the number of fundamental physical constants depends on the physical theory accepted as "fundamental". Currently, this is the theory of General Relativity for gravitation and the Standard Model for electromagnetic, weak and strong nuclear interactions and the matter fields. Between them, these theories seems to account for a total of 26 independent fundamental constants already mentioned earlier above.

Remark

The best papers that we have read so far about the details on the quite huge possible variation ranges of the Universal constants - and that debunk the fine-tuning fallacy - are *The degree of fine-tuning in our universe - and others* (see [6]) by Fred C. Adams and *The fundamental constants and their variation: observational and theoretical status* (see [552]) by Jean-Philippe Uzan and also *The Fallacy of Fine-Tuning: Why the Universe Is Not Designed for Us* (see [552]) by V. J. Stenger. We therefore recommend any reader interested in exploring the subject in greater depth (and understand the fine-tuning fallacies and lies of people have a religious agenda) to read them!

In the table below we can see ranges of parameters for viable universes according to Fred C. Adams in *The degree of fine-tuning in our universe - and others* (see [6]). The results are expressed in decades, and calculated by taking $\log_{10}(X_{\max}/X_{\min})$, where $X_{\max}$ is the maximum value a parameter could take while still being compatible with a habitable universe. $X_{\min}$ is the minimum such value. For ranges marked with an asterisk* (the weak coupling constant and the vacuum energy scale) the quoted range only applies to values above that measured in our universe; any values below that measured in our universe are allowed, without limitation:

---

[5] According to holocene calendar.

[6] In it's paper Einstein define speed of light as $c = 2AB/(t'_B - t_A)$ and still in the early 121st century (holocene calendar) there are researches who try to find a solution to measure the one-way speed of light but that are systemically debunked.

Quantity	**Observed Value**	**Range (decades)**	$X_{\max}/X_{\min}$
Up quark mass	2.3 [MeV]	>3	$>10^3$
Down quark mass	4.8 [MeV]	0.85	7.08
Electron-proton mass ratio	$1/1836$	5	10^5
Up-down quark mass difference	2.5 [MeV]	1	>10
Gravitational constant	$6\cdot10^{-39}$	>10	$>10^{10}$
Weak coupling constant	10^{-5}	6*	10^6
Fine structure constant	$1/137$	4	10^4
Strong coupling constant	15	3	10^3
Fluctuation amplitude	10^{-5}	4	10^4
Baryon to photon ratio	$6\cdot10^{-10}$	6	10^6
Dark matter abundance	$3\cdot10^{-9}$	6	10^6
Vacuum energy scale	0.0003 [eV]	10*	10^{10}

In a survey made on 79 professional physicists (see [96]) in 12024 (holocene calendar) we get the following result for the opinion of professional scientist about the values of the constants:

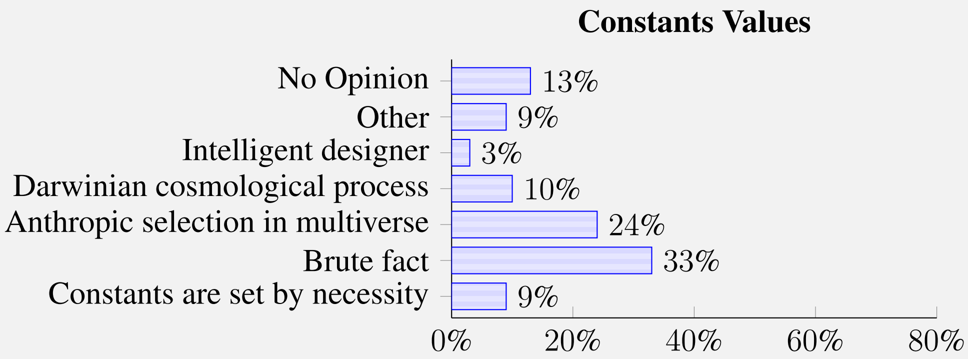


Figure 9.5: Copenhagen survey on how the "Big Bang" should be understood

The developments of high energy physics theories such as multi-dimensional (Kaluza-Klein) and string theories provide new motivations to consider the time variation of the fundamental constants. The observation of the variability of these constants constitutes one of the very few hope to test directly the existence of extra-dimensions and to test these high energy-physics models.

> *The Universe is not fine-tuned to us: We are fine-tuned to our particular Universe!*
>
> Victor. J. Stenger

quote 9.1:3117.#61

Caution! The readers must be careful about the fallacy of "fine tuning argument" from people having very likely a precise agenda and using only rhetorical arguments to manipulate their audience (we have already speak about the danger of rhetoric in this textbook introduction). As we will prove it during all coming chapters and sections, most constants can vary (more or less in a given range) from their actual value without forbidding universe, stars, planets and life to emerge (and even if the constants can vary of only $\pm 0.1\%$ as we have proved it in the section of Set Theory - Cantor theorem at page 232 - there are as many infinite numbers in a small range of $\mathbb{R}$ than in the whole set of $\mathbb{R}$, i.e. the infinite choices of values are of same cardinal... therefore speaking of "fine tuning" for an infinite possibility of choices is quite a non-sense).

So claiming that only a very small subset of constant values permits the existence of intelligent life is mathematically a non-sense as all sets have the same cardinal! Furthermore the proponents of fine-tuning make serious undergraduate level errors in physics, cosmology, probability theory, data analysis and even worst in the basics understanding of the scientific method (keep in mind by the way that $99.9999999999999999999999999999999999999999999999999999999999999999999\%$ at least of the observable universe cannot sustain life and only 15% of Earth can naturally support humans and that almost $6,000$ genetic disease are known so far... and that the human body has almost weekly cells that turn out into small cancers...). While not every proponent makes every error, there is a remarkable similarity to the arguments you find in the theist literature, which leads you to suspect that they do not do much research to support their claims beyond simply reading each other's books. With so many errors and misjudgements, and with such a gross lack of understanding of the basic science we have seen exhibited by the supporters of supernatural fine tuning, we can safely say that their motivation is more wishful thinking than truthful scientific inference.

A proper analysis finds there is no evidence that the Universe is fine-tuned. In their 12006 (holocene calendar) paper Roni Harnik, Graham Kribs, and Gilad Perez (see [231]) put forward a universe that seems capable of creating preconditions for life and yet has fundamental particles entirely different from our own. In 12013 (holocene calendar), Abraham Loeb, of Harvard, argued (see [356]) that a primitive form of life might have been possible in the early universe. Fred Adams and Evan Grohs showed that if we vary several parameters in our theories at once, there are ways for stars to produce carbon other than the mechanism Hoyle predicted it's just that those other options conflict with observations that Hoyle already knew of. The reader can also read [511] if interested in a undergraduate treatment of this fallacy.

These three examples show that a chemistry complex enough to support life can arise under circumstances that are not anything like the ones we experience, and therefore our universe isn't all that special!

9.1.3.3 Astronomical/Astrophysical parameters and constants

Obviously an astronomical or astrophysics parameter is a physical "constant" used in astronomy theoretical models that in fact vary with time and can be obtained only by measurement.

There are billions of astronomical/astrophysics parameters but here are the really basic ones that every civilized person should have read at least once in their life:

Name	**Symbol**	**Value**	**Unit**
Diameter of the Sun	$D_\odot$	$1392 \cdot 10^6$	m
Earth's average gravitation	g	9.81	m·s^{-1}
Mass of the Sun	$M_\odot$	$1.989 \cdot 10^{30}$	kg
Rotational period of the Sun	$T_\odot$	25.38	days
Radius of Earth	R_A	$6.378 \cdot 10^6$	m
Mass of Earth	M_A	$5.976 \cdot 10^{24}$	kg
Rotational period of Earth	T_A	23.96	hours
Earth orbital period	Tropical year	365.24219879	days
Astronomical unit	AU	$1.4959787066 \cdot 10^{11}$	m
Light year	lj	$9.4605 \cdot 10^{15}$	m
Parsec (Sun-Earth distance)	pc	$3.0857 \cdot 10^{16}$	m
Hubble constant (non-SI)	H_0	73.52 ± 1.62	km·s^{-1}·Mpc^{-1}
Hubble constant (SI units)	H_0	$2.4305(\pm 0.0525) \cdot 10^{-18}$	s^{-1}
Universe critical density	ρ_c	$5 \cdot 10^{-27}$	kg·m^{-3}

Remark

The astronomical unit (AU) was initially the Earth-Sun distance but as the latter varies obviously with time it has become a standardized value at $149,597,870,700$ [m] by the XXVIII General Assembly of International Astronomical Union. However notice that in modern times, Earth-Sun distance is measured using telemetry (radar echo) with an accuracy of a dozen of meters only (see [286])!

9.1.3.4 Chemical parameters

The physicochemical parameters are physical constants that are especially found in all areas relating to chemistry and thermodynamics.

There are also billions of physicochemical parameters, but here are the really basic ones that every civilized person should have read at least once in their life:

Name	**Symbol**	**Value**	**Unit**
Standard Pressure	P_0	$101,325$	Pa
Standard Temperature	T	293.15	K
Molar Volume	V_M	22.4141	l mol^3

Remark

The reader interested in the properties of chemical elements can download the periodic table of elements proposed in the download section of the companion website.

9.1.3.5 Material parameters

The material parameters are especially found in all areas relating to mechanics, electrodynamics, thermodynamics, architecture, civil engineering, etc.

Name	Symbol	Value	Unit
Refractive index of vacuum	n	1	
Refractive Vacuum/Air ($\lambda = 589.29$ [nm])	n	1.000293	
Refractive Vacuum/Water ($\lambda = 589.29$ [nm], 293 [K])	n	1.330	
Refractive Vacuum/Diamond ($\lambda = 589.29$ [nm])	n	2.419	
Refractive Vacuum/Ethanol (ethyl alcohol) ($\lambda = 589.29$ [nm])	n	1.361	
Resistivity copper (293 [K])	ρ	0.017	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity aluminium (293 [K])	ρ	0.0278	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity sast steel (293 [K])	ρ	0.13	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity silver (293 [K])	ρ	0.016	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity carbon (293 [K])	ρ	40	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity pure steel (293 [K])	ρ	0.1	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity quicksilver (293 [K])	ρ	0.941	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity gold (293 [K])	ρ	0.0222	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity lead (293 [K])	ρ	0.208	$\Omega\cdot\text{mm}^2\cdot\text{m}^{-1}$
Resistivity bakelite (293 [K])	ρ	10^{18}	$\Omega\cdot\text{cm}$
Resistivity pure water (293 [K])	ρ	10^{7}	$\Omega\cdot\text{cm}$
Resistivity marble (293 [K])	ρ	10^{10}	$\Omega\cdot\text{cm}$
Resistivity glas (293 [K])	ρ	10^{15}	$\Omega\cdot\text{cm}$

9.1.3.6 Planck's constants

The Planck's constants are mainly physical curiosities that arise from a specific system of units and whose values in the S.I. system are given in the table below (for their derivation see page 4905):

Name	Symbol	Value	Unit
Planck length	l_P	$1.616199(97)\cdot 10^{-35}$	m
Planck area	l_P^2	$2.6121\cdot 10^{-70}$	m^2
Planck volume	l_P^3	$4.2217\cdot 10^{-105}$	m^3
Planck mass	m_P	$2.17651(13)\cdot 10^{-8}$	kg
Planck time	t_P	$5.39106(32)\cdot 10^{-44}$	s
Planck electric charge	q_P	$1.875545956(41)\cdot 10^{-18}$	C
Planck temperature	T_P	$1.416833(85)\cdot 10^{32}$	K
Planck linear momentum	$p_P = m_p \cdot c$	6.52485	kg m s^{-1}
Planck energy	$E_P = m_P c^2$	$1.9561\cdot 10^{9}$	J
Planck force	$f_P = E_P \cdot l_P^{-1}$	$1.21027\cdot 10^{44}$	N
Planck power	$P_P = E_P \cdot t_P^{-1}$	$3.62831\cdot 10^{52}$	W
Planck density	$\rho_P = m_P \cdot l_P^{-3}$	$5.15500\cdot 10^{96}$	kg m^{-3}
Planck energy density	$u_P = E_P \cdot l_P^{-3}$	$4.63298\cdot 10^{113}$	J m^{-3}
Planck energy intensity	$I_P = u_P \cdot c$	$1.38893\cdot 10^{122}$	W m^{-2}
Planck angular frequency	$\omega_P = t_P^{-1}$	$1.85487\cdot 10^{43}$	s^{-1}
Planck pressure	$p_P = f_p \cdot l_P^2$	$4.63309\cdot 10^{113}$	N m^{-2}
Planck electric current	I_P	$3.4789\cdot 10^{25}$	A
Planck voltage	V_P	$1.04295\cdot 10^{27}$	V
Planck impedance	$Z_P = V_P \cdot I_P^{-1}$	29.9792458	Ohm
Planck acceleration	$a_P = c \cdot t_P^{-1}$	$5.560815\cdot 10^{51}$	m s^{-2}

We see above that some Planck units are suitable for measuring quantities that are familiar from daily experience. For example:

- 1 Planck mass is only about 22 micrograms
- 1 Planck momentum is only about 6.5 $[\text{kg}\cdot\text{m}\cdot\text{s}^{-1}]$
- 1 Planck energy[7] is only about 500 $[\text{kW}\cdot\text{h}]$
- 1 Planck charge is close to only 11.7 elementary charges
- 1 Planck impedance is close to only 30 $[\Omega]$

Planck constants are based on the fact that as we will see further below that their definition comes only from properties of Nature and not from any human construct. Planck units are only one system of several systems of natural units, but Planck units are not based on properties of any prototype object or particle (that would be arbitrarily chosen), but rather on only the properties of free space.

---

[7] Much smaller than the energy produced by the Tsar Bomba $\sim 2.1\cdot 10^{17}$ [J].

In this system of units the fundamentals constants G, c, $\hbar$, $(4\pi\varepsilon_0)^{-1}$ and k (Boltzmann constant) are such that:

$$\boxed{G=c=\hbar=\frac{1}{4\pi\varepsilon_0}=k=1} \tag{9.1.49}$$

Some physicists argue that communication with extraterrestrial intelligence would have to employ such a system of units in order to be understood as it is once again the Natural choice!!!

The Planck constant are mainly physical curiosities and the reader must not see any special interpretation about them (at least as far as we know today).

Remark

For reminder, the reader interested in the exact provenance of the various Planck constants (Planck length, Planck mass, etc.) should go read the section of Wave Quantum Physics where these constants are determined with the necessary details at page 4905.

The table below shows how the use of Planck units simplifies many fundamental equations of physics that we will prove in details in the next chapters, because this gives each of the five fundamental constants, and products of them, a simple numeric value of 1. In the SI form, the units should be accounted for. In the non-dimensionalized form, the units, which are now Planck units, need not to be written if their use is understood.

Model	SI form	Non-dimensionalized form
Newton's gravitational law	$F=-G\frac{m_1m_2}{r^2}$	$F=-\frac{m_1m_2}{r^2}$
Coulomb's law	$F=\frac{1}{4\pi\varepsilon_0}\frac{q_1q_2}{r^2}$	$F=\frac{q_1q_2}{r^2}$
Einstein field equations	$G_{\mu\nu}=8\pi\frac{G}{c^4}T_{\mu\nu}$	$G_{\mu\nu}=8\pi T_{\mu\nu}$
Mass–energy equivalence	$E=mc^2$	$E=m$
Energy–momentum relation	$E^2=m^2c^4+p^2c^2$	$E^2=m^2+p^2$
Thermal energy	$E=\frac{1}{2}kT$	$E=\frac{1}{2}T$
Planck-Einstein relation	$E=h\nu=\hbar\omega$	$E=\omega$
Planck's law	$I(\omega,T)=\frac{\hbar\omega^3}{4\pi^3c^2}\frac{1}{e^{\frac{\hbar\omega}{k_BT}}-1}$	$I(\omega,T)=\frac{\omega^3}{4\pi^3}\frac{1}{e^{\omega/T}-1}$
Stefan–Boltzmann constant	$\sigma=\frac{\pi^2k_B^4}{60\hbar^3c^2}$	$\sigma=\frac{\pi^2}{60}$
Schrödinger's equation	$-\frac{\hbar^2}{2m}\nabla^2\left(1+V(\vec{r})\right)\Psi(\vec{r},t)=\mathrm{i}\hbar\dot{\Psi}(\vec{r},t)$	$-\frac{1}{2m}\nabla^2\left(1+V(\vec{r})\right)\Psi(\vec{r},t)=\mathrm{i}\dot{\Psi}(\vec{r},t)$
Dirac covariant equation	$(\mathrm{i}\hbar\gamma^\mu\partial_\mu-mc)\psi=0$	$(\mathrm{i}\gamma^\mu\partial_\mu-m)\psi=0$
Maxwell Equations	$\vec{\nabla}\circ\vec{E}=\dfrac{1}{\varepsilon_0}\rho$ $\vec{\nabla}\circ\vec{B}=0$ $\vec{\nabla}\times\vec{E}=\dfrac{\partial\vec{B}}{\partial t}$ $\vec{\nabla}\times\vec{B}=$ $\dfrac{1}{c^2}\left(\dfrac{1}{\varepsilon_0}\vec{j}+\dfrac{\partial\vec{E}}{\partial t}\right)$	$\vec{\nabla}\circ\vec{E}=4\pi\rho$ $\vec{\nabla}\circ\vec{B}=0$ $\vec{\nabla}\times\vec{E}=\dfrac{\partial\vec{B}}{\partial t}$ $\vec{\nabla}\times\vec{B}=$ $4\pi\vec{j}+\dfrac{\partial\vec{E}}{\partial t}$

Table 9.14: **Simplification of physics equations in Planck units**

Despite the examples given how many constant are there? Why play they a "central role" in physical theories? Do they all have the same importance or are some of them more fundamental than the others? Following what criteria? Can we then test whether they are really constant?

To try to answer some of these questions, first of all we must notice that at each step of our theoretical constructions there remain some constant parameters that are not and can not be explained in terms of more fundamental quantities, simply because these latter do not exist in the state of our knowledge. When the theories are refined, it is possible that a constant is explained in terms of new parameters, more fundamental. Thus, the mass of the proton is a fundamental constant of nuclear physics, but must in principle be able to calculate, within the framework of quantum chromodynamics, according to the quark masses and energies of the electromagnetic and strong interactions. This change of status is associated with that of the proton, which is of elementary particle become a composite body.

We will define constants modestly as all non-determined parameters in a given theoretical framework. This definition is equivalent to accept that we are unable to write an evolution equation for these constants and that thus revealed the limit of what the theories in which they appear are able to explain. However the constancy hypothesis is implicitly controlled by experimental validation of these theories. The results of experiments must be reproducible at various times and in various laboratories. If this is the case, within the limits of experimental details, then it is legitimate to consider that the constancy hypothesis is valid. This definition implies that there is no absolute constants list, because such a list depends on the theoretical frameworks chosen to describe the Nature and may change with the progress of knowledge.

Now arises the question whether it is possible to characterize more precisely the concept of constant and determine whether, among all the constants, some are more fundamental than others. For this, we must first prove a relation between constants and units.

Thus, Planck discovered in 11900 (holocene calendar) that it was possible to use the three fundamental physical constants:

$$\boxed{\begin{aligned} G &\cong 6.67408(31)\cdot 10^{-11} && [\mathrm{m}^3\cdot\mathrm{s}^2\cdot\mathrm{kg}^{-1}]\\ c &\cong 299,729,458 && [\mathrm{m}\cdot\mathrm{s}^{-1}]\\ \hbar &= \frac{h}{2\pi}\cong 1.05\cdot 10^{-34} && [\mathrm{J}\cdot\mathrm{s}] \end{aligned}} \tag{9.1.50}$$

to define the three units of mass, time and length from the Planck mass, the Planck length and the Planck time (see again the chapter of Atomistic for the mathematical approach for determining their values).

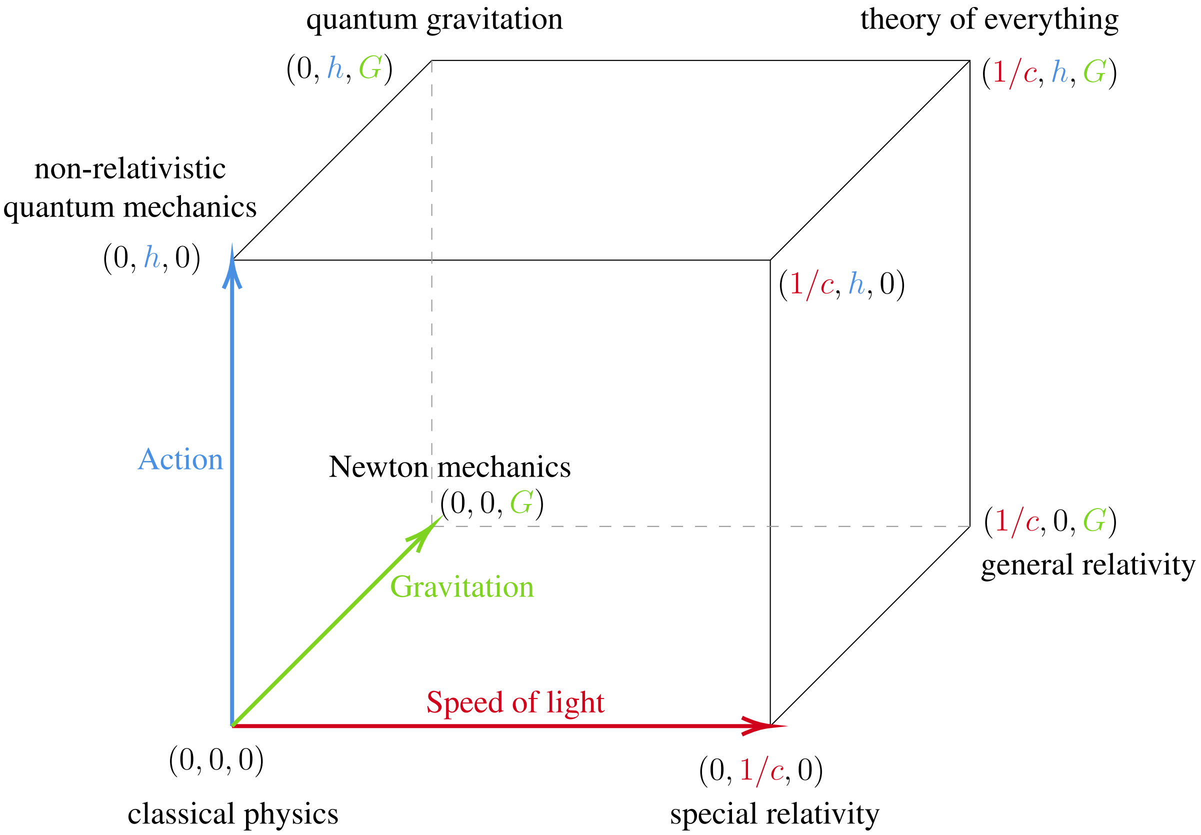
Planck named those units "Natural System Units" (NSU) because they are independent of a body or a material and [...] necessarily retain their significance for all times and all civilizations, even for aliens or non-human one. The significance of these units take long to emerge in the theoretical physicists community. They point the scales where quantum mechanics and gravitation become of the same amplitude. They are therefore very suited to the study of primordial cosmology and to that of Black Holes and relativistic quantum mechanics.

The choice of Planck units as natural units is linked to the considerations justifying that G, c, $\hbar$ are the three most fundamental constants (known at this date). In these units, the numerical value of these three fundamental constants is 1 as we have already noticed earlier above.

The role of the constants in the structure of physic theories can be quite beautifully illustrated by the magic cube named the "Okun cube" of physical theories visible in the figure below (whose validity remains to be check of course). The idea is to "turn on" or "turn off" one by one the three fundamental constants to see how physical theories are articulated with each other.

Remark

The reader will certainly better understand the explanations that follow when it will have studied and read the sections of General Relativity, Quantum Field Theory and therefore the Wave Quantum Physics, so if necessary he can skip the following explanations.



quantum gravitation
theory of everything
$(0, h, G)$
$(1/c, h, G)$
non-relativistic quantum mechanics
$(0, h, 0)$
$(1/c, h, 0)$
Action
Newton mechanics
$(0, 0, G)$
$(1/c, 0, G)$
general relativity
Gravitation
Speed of light
$(0, 0, 0)$
classical physics
$(0, 1/c, 0)$
special relativity

Figure 9.6: Okun cube (author: Juergen Giesen)

When G is set to 0, this means removing all the gravitational forces and decoupling the matter of space and time. When $\hbar$ is set to 0, we delete the quantum character of nature and we decouple the corpuscular and wave nature (consequence of De Broglie relation), when $1/c$ is set to 0, the speed of light is infinite and the time and space are uncoupled from each other (consequence of Lorentz transformation). To visualize this, we consider the cube above introduced by the Soviet physicist Mikhail Bronshtein, who gets an idea originally developed by Lev Landau, Dmitri Ivanenko and Georgi Gamow.

Naturally, at the lowest level $(0, 0, 0)$, we find the Newtonian mechanics, which does not take into account relativistic, quantum or gravitational effects. At the top level where we consider the effect of one constant, we find the three of Special Relativity $(1, 0, 0)$, quantum mechanics $(0, 1, 0)$ and Newtonian gravitation $(0, 0, 1)$, three theories tested with great precision in their field of validity and therefore having the status of "scientific theory".

At an even higher level, the Quantum Field Theory in $(1,1,0)$ takes into account the quantum and relativistic effects; the General Relativity in $(1,0,1)$ takes into account the gravitational and relativistic effects, and Newtonian quantum gravity in $(0,1,1)$ is supposed to provide a quantum and non-relativistic description of gravity. Only the first two theories are currently tested experimentally and have therefore the status of "scientific theory".

The ultimate actual level is at $(1,1,1)$ the "theory of everything" (name very pretentious and too commercial), supposed to give a quantum and relativistic description of gravity. Its formulation is not yet known, even if String Theories (see section of the same name page 6099), intensively studied nowadays seem to be a serious candidates. These theories appear as limiting cases of a broader and deeper theory but not yet formulated: the M theory (M states for "Mother").

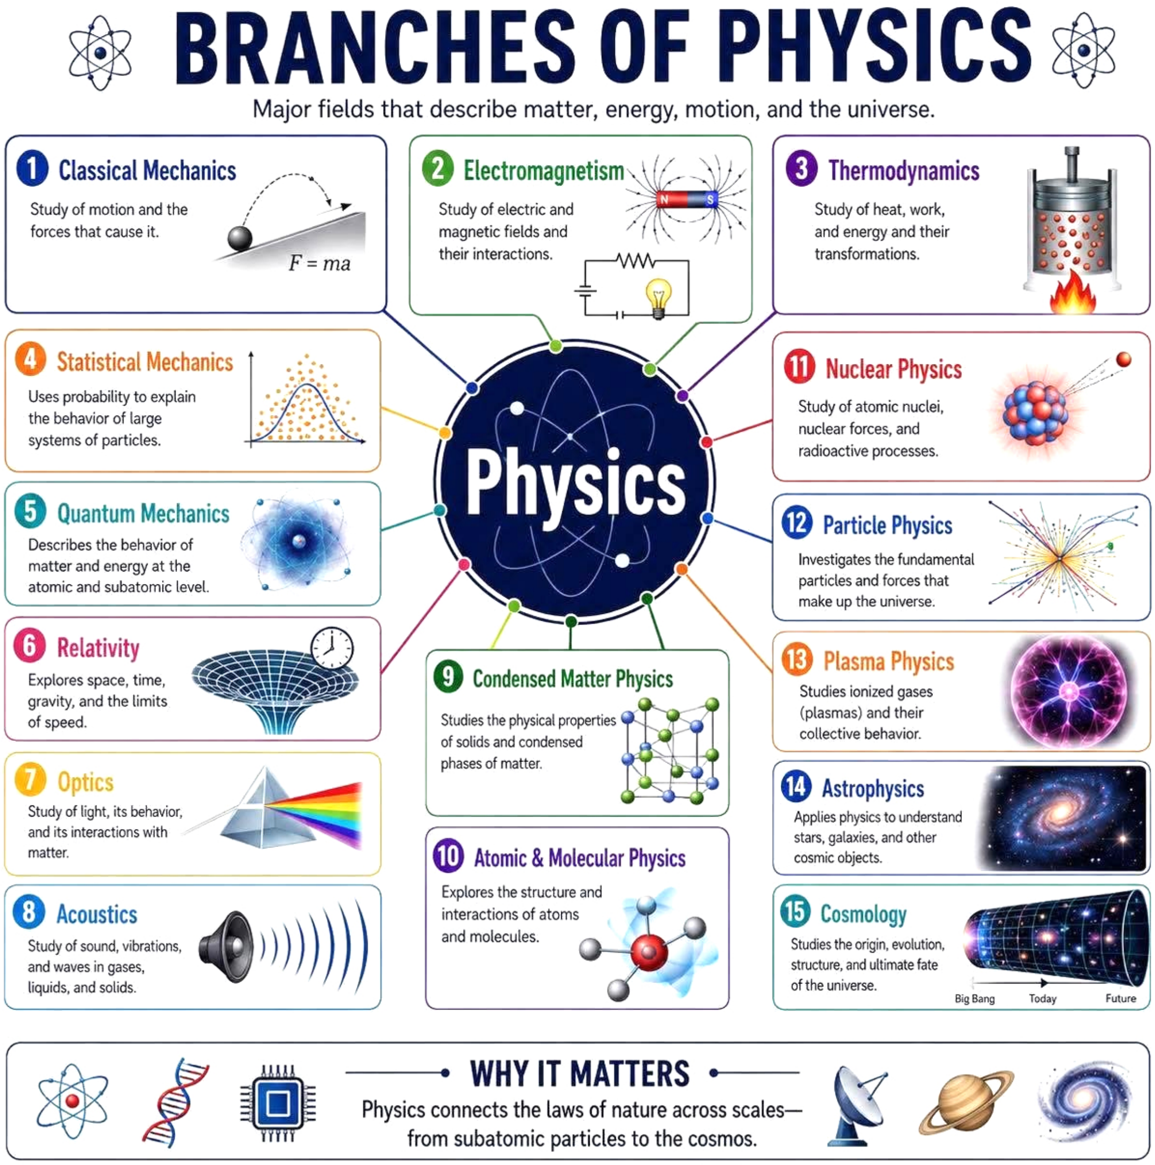
Caution!!! There is no principle of physics yet (in the beginning in the 121st century according to holocene calendar) that says physicals laws or constants have to be the same everywhere and always. Indeed, the reader must remember that the "laws" of physics are **descriptive**, not **imperative** and therefore they are some observed regularity in what we can observe experimentally with sufficiently wide occurrence or relevance! Asking whether the laws can change is no more and no less than asking whether regularities which have been observed up till now might not be quite as universal as was thought. The answer to that is: YES! This could drive the reader a bit mad. Indeed, how can we possibly do Science if the rules keep changing? But if you are a professional active scientist, you have to face up to that possibility - and you have a responsibility to check out if there is evidence beyond reasonable doubt about it! We will repeat this warning multiple times in this textbook as its seems that this is something necessary!

9.1.4 Principles of Physics

The advances of science in general and physics in particular were based two centuries before mainly on experimentation, that is to say that we reproduced in the laboratories given phenomena to analyse them systematically (the reproducibility with a given accuracy validating a hypothesis). This was equivalent as asking systematically specific questions to Nature and to describe and study the reactions caused thereby. The repetition at will of a phenomenon in an experiment would not be guaranteed if there was not a general principle of causality.

> *Physics doesn't captivate everyone - but if it draws you in naturally, take pride in being among the rare few whom the Universe seems to have chosen to explore its mysteries up close.*

quote 9.1:3127.#62



BRANCHES OF PHYSICS

Major fields that describe matter, energy, motion, and the universe.

Physics

1. **Classical Mechanics** Study of motion and the forces that cause it.

2. **Electromagnetism** Study of electric and magnetic fields and their interactions.

3. **Thermodynamics** Study of heat, work, and energy and their transformations.

4. **Statistical Mechanics** Uses probability to explain the behavior of large systems of particles.

5. **Quantum Mechanics** Describes the behavior of matter and energy at the atomic and subatomic level.

6. **Relativity** Explores space, time, gravity, and the limits of speed.

7. **Optics** Study of light, its behavior, and its interactions with matter.

8. **Acoustics** Study of sound, vibrations, and waves in gases, liquids, and solids.

9. **Condensed Matter Physics** Studies the physical properties of solids and condensed phases of matter.

10. **Atomic & Molecular Physics** Explores the structure and interactions of atoms and molecules.

11. **Nuclear Physics** Study of atomic nuclei, nuclear forces, and radioactive processes.

12. **Particle Physics** Investigates the fundamental particles and forces that make up the universe.

13. **Plasma Physics** Studies ionized gases (plasmas) and their collective behavior.

14. **Astrophysics** Applies physics to understand stars, galaxies, and other cosmic objects.

15. **Cosmology** Studies the origin, evolution, structure, and ultimate fate of the universe.

WHY IT MATTERS

Physics connects the laws of nature across scales—from subatomic particles to the cosmos.

9.1.4.1 Principle of Causality

Definition (#9.1.419): We define the "principle of causality" by the fact that in exactly the same conditions, the same causes always lead to the same effects. In other words, if certain initial conditions are well known, the phenomenon will take place in a determined manner, always the same (at least in Classical Physics, but not in Quantum Physics!!!).

In fact, experience is not always necessary if we consider the special case of "first order principles" which are by definition “*basic proposition or assumption that cannot be deduced from any other proposition or assumption*”.

This method involves breaking a problem down to its most basic, established laws and building up a solution from there. A key example is deriving an empirical law, like the Stefan-Boltzmann law, directly from fundamental physics principles, rather than using experimental data.

However, our modern society often give only a little time left to the great people of science to think about these first-order principles by imaginary experiences (very popular method used by Albert Einstein for the parenthesis...).

It is in a trilemma proposed by the scepticist of antiquity named Agrippa, according to an argument reported by Sextus Empiricus, that the question of justification of knowledge (based on reasoning and not on instrumentalism!) has been put most explicitly:

H1. Knowledge is ultimately based on first principles but arbitrary one (axiomatic argument, which rests on accepted precepts).

H2. Or we do not find such principles and we have an infinite regress (regressive argument, in which each proof requires a further proof, ad infinitum).

H3. Or justification is circular (circular argument, in which theory and proof support each other).

The last two methods of reasoning are fundamentally weak, and because the Greek sceptics advocated deep questioning of all accepted values, they refused to accept proofs of the first sort. The trilemma, then, is the decision among the three equally unsatisfying options.

This trilemma has also often, in contemporary philosophy, especially by Karl Popper, be nameed "Fries trilemma" or "Münchhausen trilemma" or "Agrippa trilemma" and we currently do not know in what scenario (H1, H2 or H3) we are.

On multiple occasions in history, it has been asked how we can know for certain what is true and what is not. For example, it is possible that rather than being many billions of years old as the scientific evidence strongly suggests, the Universe was actually made last Thursday. It is also possible that the entire world is the creation of your own mind, like a dream it takes you several decades to wake up from. Again, the is why we never speak about "proofs" in experimental science but about "strong statistical evidence", or "statistical evidence above any reasonable doubts" (see section Statistics page 948), and "consensus".

Attempts to attach any objective importance to speculations on this latter topic may alternatively be called "bullshit"...

Let us now introduce these fundamental principles (or assumptions):

9.1.4.2 Principle of Conservation of Energy

The first principle of conservation of energy is stated as following (basically at least... see below ... for some remarks ...): The total energy, denoted E or E_{tot} of any isolated and inertial system does not vary with time relatively to a fixed reference frame if there is no transfer of energy (or mass/radiation) or heat from outside the system.

This principle can be expressed by the formula:

$$\boxed{\Delta E_{\text{tot}} = \Delta U + \Delta E_c + \Delta E_p} \qquad (9.1.51)$$

where ΔE_{tot} is the total energy variation of the system, ΔU the variation of internal energy of the system, that is to says its own energy corresponding to the kinetic and potential microscopic energies of particles that constitute it.

The term ΔE_c, also sometimes denoted ΔE_{cin}, is the change in kinetic energy at a macroscopic scale (motion of the system in a given reference frame) and the term ΔE_p, also sometimes denoted ΔE_p, the variation of potential energy at a macroscopic scale, for the system interacting with gravitational or electromagnetic fields.

In physics, a conservation law (nothing is lost, nothing is created) expresses the idea that a particular measurable property of a local isolated physical (closed) system remains constant during the evolution of this system. For example for energy this means in the case of a conservative system:

$$\Delta U + \Delta E_c + \Delta E_p = 0 \qquad (9.1.52)$$

The list below lists some conservation laws useful to the engineer and have never been put in default as far as we know until this day and resulting for most of them of the conservation energy principle:

- Conservation of inertia
- Conservation of momentum
- Conservation of angular momentum
- Conservation of electric charge
- Conservation of the magnetic flux
- Conservation of mass

The Noether's theorem that we will see further below expresses the equivalence between conservation laws and invariance of physical laws regarding certain transformations (typically named "symmetries")!!!!!!

This theorem applies only to system describable by a Lagrangian (see next section of Analytical Mechanics). For example, the invariance by translation over time implies that energy is conserved (!!!), the translation invariance in space implies that the amount of movement is maintained (!!!), and the rotation invariance in space implies that the angular momentum is conserved (!!!).

This equivalence can be proven and follows from the invariance in time of the laws of physics. This is the first Noether's principle (theorem) that we'll prove a little further below.

Remarks

R1. Energy can be found as we know in several forms (this does not to mean that there are several types of energies!!!) as heat, kinetic energy, potential, electrical, magnetic, etc.

For example, in consumer applications, including in the field of nutrition, we often express the energy in "calories". The calorie being strictly speaking the energy we must provide to heat up one gram of pure water of one degree Kelvin (or one degree Celsius) in standard conditions of pressure as we will see more in details in the section of Thermodynamics (we can convert calories to joules by multiplying by approximately 4.186). Even worst... nutritionists name for communication purposes "calorie" what physicists name (properly) "kilocalorie".

R2. The violation of this principle of conservation of energy in an isolated system has never been observed but its validity can not be proved as far as we know (hence the fact that it is a "first principle").

R3. Some physicists are debating the fact that this first principle follows from Noether's theorem we shall see. But it is quite debatable as Noether's theorem considers the potential energy as constant over time...

9.1.4.3 Principle of Least Action

The "principle of least action" (also named "variational principle") is stated as following:

All natural phenomena are consistent with the fact that Nature, in producing its effects, always acts by the simplest and most direct way.

This single rule as we will see it through this entire book underpins all of physics.

With this statement and the principle of conservation of energy, we can then establish a great powerful mathematical tools for the study of theoretical physics. But we can not introduce this tool at this level of our discussion since it requires mathematical tools that we will introduce later in details, in the section of Analytical Mechanics (during the study of the Lagrangian formalism to be more precise at page 3155).

Meanwhile here are the two main relations that summarize this principle:

$$\boxed{\begin{gathered}S(q,\dot{q})=\int\limits_{t_A}^{t_B}L(q,\dot{q})\mathrm{d}t\\ \frac{\partial L}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}=0\end{gathered}} \tag{9.1.53}$$

We will see through this textbook that all 121st century (holocene calendar) science can actually be derived from the latter, like Quantum Field Theory and General Relativity for example (and we will prove that in details in the corresponding sections of our book!).

Remark

The violation of this principle in an isolated system has never been observed as far as we know but its validity can also not be proved as far as we know (hence the fact that it is also a "first principle").

If evolution by natural selection can be connected to the Principle of Least Action, which has been theorised on for many years, then it corresponds to the direction of Ultimate Causation. As an organism evolves and follows a path of Proximate Causation, if the vector is closely parallel to that of the Ultimate Causation then the changes will confer desirable heritable attributes which will lead to further development. If however the variations do not occur in a direction close to the of the Ultimate Causation vector the evolved organism will quickly die out. This may be viewed as similar to Feynman's sum over all histories. Therefore, the Principle of Least Action gives a direction to Evolution.

9.1.4.4 Noether's Principle (Noether's theorem)

The Noether's principle, traditionally named "Noether's theorem" as it can be proved, combines elegantly conserved physical quantities to the symmetries of the laws of nature!!!

That is:

- Translational symmetry in the time (time invariant phenomenon) corresponds to the energy conservation
- Translation in the space corresponds to the conservation of momentum (quantity of motion)
- Rotation in space corresponds to the conservation of angular momentum
- Gauge transformations corresponds conservation of electric charge (see section Quantum Field Theory page 5180), weak and color charge.

The reader must keep in mind that energy and momentum are not the same because they are fundamentally different quantities: momentum is a vector (it has direction) and is defined by mass times velocity, while energy is a scalar (it has no direction) and is related to the capacity to do work!

In other words, Noether's theorem states that physics is:

- Symmetrical (invariant) by translation in time (this having the consequence that there is no origin in time)
- Symmetrical (invariant) by translation in space (this having the consequence that there is no origin in the space)
- Symmetrical (invariant) by rotation (this having the consequence that there is no preferred direction in space)

Noether's theorem is important, both because of the insight it gives into conservation laws, and also as a practical calculational tool. It allows investigators to determine the conserved quantities (invariants) from the observed symmetries of a physical system. Conversely, it allows researchers to consider whole classes of hypothetical Lagrangians with given invariants, to describe a physical system. As an illustration, suppose that a physical theory is proposed which conserves a quantity X. A researcher can calculate the types of Lagrangians that conserve X through a continuous symmetry. Due to Noether's theorem, the properties of these Lagrangians provide further criteria to understand the implications and judge the fitness of the new theory.

Remarks

R1. This theorem implies that a Galilean reference frame (see section Classical Mechanics page 3157) is homogeneous (no privileged time or space origin) and isotropic (no preferred direction).

R2. We must not confuse between the invariance of the laws and the non-invariance of the theoretical solutions which lead to these laws! For example, the discharge of a capacitor (see section Electrical Engineering page 8467) is translation invariant in time but not its solution.

This result established in 11915 (holocene calendar) by Emmy Noether just after arriving in Göttingen, was described by Albert Einstein as "*monument of mathematical thinking*". It is now one of the pillars of theoretical physics.

Today it is still often presented only during course on Quantum Field Theory. This makes it seem more complicated and mysterious than it is, and this is forget that it also applies to Classical Mechanics!!!

Remark

We recommend to most readers to read the proof of Noether's theorem in parallel of the section Analytical Mechanics (see page 3155).

Thus, symmetries play a major role in physics. They allow in one hand to simplify the problems and on the other hand to draw new laws. To illustrate the first application of symmetries let us simply evoke the mathematical form of the gravitational potential generated by a punctual mass located at the origin of reference frame (see section Classical Mechanics page 5266). In Cartesian coordinates, the expression of the gravitational potential is relatively complex:

$$\phi=-\frac{G}{\sqrt{x^2+y^2+z^2}} \tag{9.1.54}$$

while in spherical coordinates (coordinate system that takes advantage of the spherical symmetry of the potential) it takes a very simple form:

$$\phi=-\frac{G}{r}\;[\text{J}\cdot\text{kg}^{-1}] \tag{9.1.55}$$

The properties of symmetry of a problem are exploited here in order to simplify the mathematical treatment of physical laws. Although these mathematical considerations tell us about the physical properties of the system considered, they conserve however a purely technical nature.

Symmetries also found another application whose physical significance is much deeper. The fact, not accidental, that a system possesses symmetries should certainly have physical implications. Intuitively, we understand that the presence of symmetries in a physical system translates the invariance of some of its physical properties under the application of space-time transformations or, more generally: under geometric transformations. The invariance of physical properties must necessarily induce relations of a new kind between the variables of the system. Such relations must in turn reveal deeper laws that combine the geometry of the system to the laws of Nature. This reasoning, even if it is intuitive, invites us to delve deeper into the relations that may exist between the physics laws and the geometrical properties of space-time.

Let us consider a mechanical experience more or less complex observed simultaneously by two physicists O and O' at rest or in uniform translation located in different places as each of them chooses a reference frame which he is the origin.

They undertake to measure various physical quantities and obtain numerically results that generally differ. However, the physical laws they draw (same level of knowledge) are identical!! This conclusion is trivial because we all know that the laws of Nature must not depend not on the location of the observers in uniform translation or a rest.

Mathematically, the difference between repositories O and O' following the chosen reference frame of the studied experiment is the change of basis from one to the other by a rotation $R(\phi)$ and / or translation $T(l)$ (see section Euclidean Geometry page 2640).

The fact that the physical laws are independent of the position of the observer means that they do not vary after have applied to them a rotation and / or translation. We then say that they are "invariant under rotation and translation" or they are "symmetrical in rotation and translation".

Remark

In physics, the definition of symmetry is similar to that of mathematicians but applies to the laws of nature and not the geometric figures. Thus a physical symmetry is a transformation of system variables - which may be geometrical variables or more abstract variables - that does not change the formulation of physical laws.

Let us give a more or less rigorous definition of a physical symmetry.

Before let us consider a system S whose state evolves over time. Let us denote the state of S at time t by $S(t)$. Then at the initial moment t_0, S is therefore in the state $S(t_0)$. Let us consider a geometrical transformation T (rotation or translation) that acts at each point of space and optionally of time. In a time t, the action of T on the system S has for effect of transforming it into a system $S'(t)=T[S(t)]$ such that at the moment t_0, the transformation by T of $S(t_0)$ is $S'(t_0)$.

Definition (#9.1.420): A transformation T named a "physical symmetry" if the transformation by T of a system S (which gives S') evolves in the same way as S, that is to say, if we apply the laws physics on $S'(t_0)$ to know its states S'' in a later time t then $S''(t)=S'(t)=T[S(t)]$.

9.1.4.4.1 Invariance by translation in space

Let us consider an isolated system consisting of n interacting particles identified by the position vectors $\vec{r}_i$. The interaction of two particles i,j derives from a potential $\varphi(\vec{r}_i,\vec{r}_j,t)$ (see section Classical Mechanics page 3351). Each particle is subjected to forces resulting from the interaction with other particles. For a given particle i for example, the resultant of these forces is expressed according to Newton's second law (see section Classical Mechanics page 3202):

$$\vec{F}_i(\vec{r},t)=m\ddot{\vec{r}}(\vec{r}_i,t)=\sum \vec{F}_{i,j}(\vec{r}_i,\vec{r}_j,t)=\sum -m\vec{\nabla}\cdot\varphi(\vec{r}_i,\vec{r}_j,t) \tag{9.1.56}$$

Let us apply to the system the following translation in space:

$$\vec{r}_i \rightarrow \vec{r}_i^{\,\prime}=\vec{r}_i+\vec{l} \tag{9.1.57}$$

where $\vec{l}$ is any space direction vector.

Say that the translation in space of a system is a symmetry means that the acceleration and the force acting on each particle are unchanged after the transformation:

$$\vec{F}_i(\vec{r},t)=\vec{F}_i(\vec{r}_i+\vec{l},t) \tag{9.1.58}$$

Which implies:

$$\sum -m\vec{\nabla}\cdot\varphi(\vec{r}_i+\vec{l},\vec{r}_j+\vec{l},t)=\sum -m\vec{\nabla}\cdot\varphi(\vec{r}_i,\vec{r}_j,t) \tag{9.1.59}$$

This equality must be true regardless of the position of the particles, so whatever are the $\vec{r}_i$ and the $\vec{r}_j$. It is clear that the only way to check the last equality in these conditions is to equalize then by pairs the potential between each particle j with the particle i, that is to say:

$$\varphi(\vec{r}_i+\vec{l},\vec{r}_j+\vec{l},t)=\varphi(\vec{r}_i,\vec{r}_j,t) \tag{9.1.60}$$

The potentials are then necessarily (and this is the power of Noether's theorem!) functions of the $\vec{r}_i-\vec{r}_j$ such that:

$$\varphi(\vec{r}_i,\vec{r}_j,t)=\varphi(\vec{r}_i-\vec{r}_j,t) \tag{9.1.61}$$

Therefore, we deduce that:

$$\vec{F}_{i,j}(\vec{r}_i,\vec{r}_j,t)=-m\vec{\nabla}\cdot\varphi(\vec{r}_i-\vec{r}_j,t)=-\left(-m\vec{\nabla}\cdot\varphi(\vec{r}_j-\vec{r}_i,t)\right)=-\vec{F}_{j,i}(\vec{r}_j,\vec{r}_i,t) \tag{9.1.62}$$

This immediately implies that the resultant of all the forces applied to the particles in the system is zero and therefore the total linear momentum is conserved:

$$\sum\vec{F}_{i,j}(\vec{r}_i,\vec{r}_j,t)+\sum\vec{F}_{j,i}(\vec{r}_j,\vec{r}_i,t)=\sum\vec{F}_i=\vec{0}\rightarrow\frac{\mathrm{d}}{\mathrm{d}t}\left(\sum m\,\dot{\vec{r}}_i\right)=\vec{0}\Leftrightarrow\sum m\,\dot{\vec{r}}_i=c^{te} \tag{9.1.63}$$

The translation invariance in space of Newton's law thus leads necessarily to:

1. The potential between the particles of an isolated system is a function of their relative distance (this will be confirmed in the section Astronomy during our study of the gravitational potential field, as well as in the section of Electrostatics regarding the electrostatic potential and also the Yukawa potential with spherical symmetry during our study of Quantum Field Theory).
2. The law of equality between action and reaction.
3. The conservation of total linear momentum of a system!!!

As consequence of the point (3) the origin of the space is unobservable (since conservation of linear momentum is equivalent to translation invariance in space)!

9.1.4.4.2 Invariance by rotation in space

Let us request now that rotations about a fixed point are symmetrics. This property must be true whatever the considered fixed point, in particular, if the fixed point is precisely the position of one of the particles in the system. It follows that the potential necessarily follows a spherical symmetry. The forces acting between the particles are then collinear to vectors that link them.

The angular momentum of the system is then expressed as follows (see section Classical Mechanics page 3244):

$$\vec{b}=\sum\vec{b}_i=\sum m_i\vec{r}_i\times\dot{\vec{r}}_i \tag{9.1.64}$$

The derivative with respect to the time of the total angular momentum gives:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\sum m_i\frac{\mathrm{d}}{\mathrm{d}t}(\vec{r}_i\times\dot{\vec{r}}_i)=\sum m_i\frac{\mathrm{d}\vec{r}_i}{\mathrm{d}t}\times\dot{\vec{r}}_i+\sum m_i\vec{r}_i\times\ddot{\vec{r}}_i=\sum m_i\vec{r}_i\times\ddot{\vec{r}}_i=\sum\vec{r}_i\times m_i\ddot{\vec{r}}_i \tag{9.1.65}$$

But the last term of the vector product can be written:

$$m_i\ddot{\vec{r}}=\vec{F}_{ij} \tag{9.1.66}$$

where the $\vec{F}_{ij}$ are the internal system forces of the particle j acting on the particle i.

The prior-previous expression the becomes:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\sum\vec{r}_i\times\vec{F}_{ij} \tag{9.1.67}$$

We can group the terms $\vec{r}_j\times\vec{F}_{ji}$ and $\vec{r}_i\times\vec{F}_{ij}$ terms by pairs and by the property of the cross product we have necessarily:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\sum\vec{r}_i\times\vec{F}_{ij}=\vec{0} \tag{9.1.68}$$

So we conclude that the angular momentum is conserved and that the conservation of angular momentum is thus equivalent to the rotational invariance.

Consequence: there is no preferred direction in space!

9.1.4.4.3 Invariance by translation in time

The total energy of a system is the sum of the kinetic energy of its particles and the potential energy resulting from the mutual interaction of this same particles, either in the form of Classical Mechanics:

$$E_{\text{tot}}=E_c+E_p=\sum\frac{1}{2}m_i\dot{\vec{r}}_i^{\,2}+V_{i,j}(\vec{r}_i,\vec{r}_j) \tag{9.1.69}$$

We will assume that the potential $V_{i,j}(\vec{r}_i,\vec{r}_j)$ does not vary with time. This assumption is justified empirically by the fact that potential observed in nature are independent of time in closed systems at equilibrium.

Let us calculate the derivative of total energy with respect to time:

$$\begin{aligned}\frac{\mathrm{d}E_{\text{tot}}}{\mathrm{d}t}&=\frac{\mathrm{d}}{\mathrm{d}t}\sum\frac{1}{2}m_i\dot{\vec{r}}_i^2+\frac{\mathrm{d}}{\mathrm{d}t}V_{i,j}(\vec{r}_i,\vec{r}_j)=\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\sum m_i\dot{\vec{r}}_i^2+0=\frac{1}{2}\sum\frac{\mathrm{d}m_i}{\mathrm{d}t}\dot{r}_i^2+\frac{1}{2}\sum\frac{\mathrm{d}\dot{\vec{r}}_i^2}{\mathrm{d}t}m_i\\&=\frac{1}{2}\sum\frac{\mathrm{d}m_i}{\mathrm{d}t}\dot{\vec{r}}_i^2+\sum\dot{\vec{r}}_i\frac{\mathrm{d}\dot{\vec{r}}_i}{\mathrm{d}t}m_i=\frac{1}{2}\sum\frac{\mathrm{d}m_i}{\mathrm{d}t}\vec{v}_i^2+\sum\vec{v}_i\frac{\mathrm{d}\dot{\vec{r}}_i}{\mathrm{d}t}m_i\end{aligned} \tag{9.1.70}$$

But if the system is closed (no external mass input or external energy input), the term $\mathrm{d}m_i/\mathrm{d}t$ is zero (no relativistic mass change either because the speed of each particle or the entire system is constant or its variation is in average equal to zero or just because we are in a comoving reference frame). It is the same for the term $\mathrm{d}\dot{\vec{r}}_i/\mathrm{d}t$ where if the system is closed (no external mass input or external energy input) the average acceleration of each particle or the entire system relatively the center of gravity will be zero. So:

$$\frac{\mathrm{d}E_{\text{tot}}}{\mathrm{d}t}=\frac{1}{2}\sum\frac{\mathrm{d}m_i}{\mathrm{d}t}\vec{v}_i^2+\sum\vec{v}_i\frac{\mathrm{d}\dot{\vec{r}}_i}{\mathrm{d}t}m_i=\frac{1}{2}\sum 0\cdot\vec{v}_i^2+\sum\vec{v}_i\cdot\vec{0}\cdot m_i=0 \tag{9.1.71}$$

So we conclude that the total energy of such a system is a constant! The above result is often more elegantly rewritten using the Lagrangian formalism that we already know as:

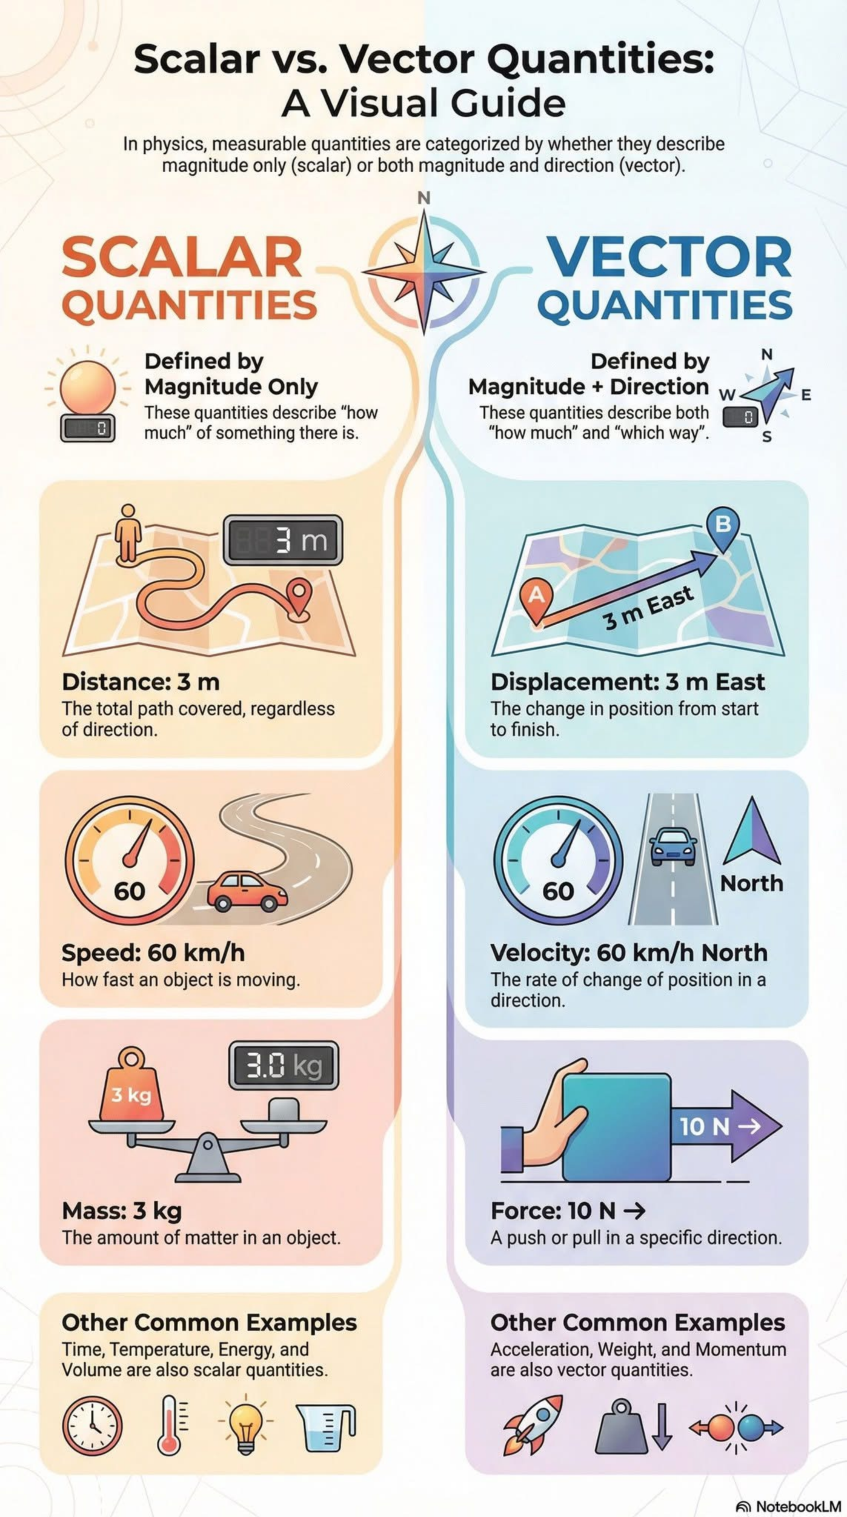
$$\boxed{\frac{\partial L}{\partial q}-\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}}\right)=0\Leftrightarrow\frac{\mathrm{d}L}{\mathrm{d}t}=0} \tag{9.1.72}$$

Caution! The Universe at its beginning was only made of radiation (photons). Therefore there was no mass, hence no time! So the law of conservation of energy doesn't apply to the beginning of the Universe as we observe it with experimental data of the early 121st century (holocene calendar)! Even the actual Universe isn't invariant by time translation because of the space frame that is expanding (see [22] and [129]). So the law of conservation applies only to small (classical) local frames typically like physics laboratories made by humans at their scale! On a very small scale, the law of conservation of energy is respected only statistically, however it is not systematically respected at the individual quantum level (see [11]).

Ask the question "*what is the mechanical quantity invariant by translation*" is equivalent to ask "*what are the mathematical quantities which are unchanged when we apply to them a translation*". There are two of them: the scalars and vectors.

Intuitively, a scalar is treated as a real number (see section Numbers page 209). But, in mechanics, the real numbers that we can construct are made from vector quantities as the vectors position, velocity, etc. For such a real number to have the status of scalar it must be independent of space. Thus, a position vector can obviously not be regarded as a scalar. The energy of the particle is a real number, but is not a scalar because as it depends explicitly, in its formulation, of the position vector.

Similarly, a vector is not only a mathematical entity having its components in a base. To have the status of vector, a mathematical entity must be transformed in the same way as the basis vectors of the vector space. By this definition, the angular momentum is not a true vector as, being the composition by the cross product of two vectors, it does not change as the basis vectors. From a mathematical point of view it is a pseudo-vector (see section Vector Calculus page 1799).



Scalar vs. Vector Quantities: A Visual Guide

In physics, measurable quantities are categorized by whether they describe magnitude only (scalar) or both magnitude and direction (vector).

SCALAR QUANTITIES

Defined by Magnitude Only

These quantities describe "how much" of something there is.

Distance: 3 m

The total path covered, regardless of direction.

Speed: 60 km/h

How fast an object is moving.

Mass: 3 kg

The amount of matter in an object.

Other Common Examples

Time, Temperature, Energy, and Volume are also scalar quantities.

VECTOR QUANTITIES

Defined by Magnitude + Direction

These quantities describe both "how much" and "which way".

Displacement: 3 m East

The change in position from start to finish.

Velocity: 60 km/h North

The rate of change of position in a direction.

Force: 10 N →

A push or pull in a specific direction.

Other Common Examples

Acceleration, Weight, and Momentum are also vector quantities.

Figure 9.7: **Reminder of scalar vs vector quantities in physics**

The only real vector that remains is the linear momentum as it is built using the derivative of the position vector which is, of course, a real vector. We conclude that the only quantity likely to be retained by translation is the total linear momentum of the system.

By similar reasoning as the above one, it is possible to assume what quantity could be invariant under rotation. Knowing that only scalar and some pseudo-vectors are indeed invariant under rotation, we conclude that the only quantity that can be retained when rotations occurs is the total angular momentum of the system.

Finally, still by the same type reasoning, the invariance of the laws of mechanics by time translation is equivalent to search the quantities conserved by a translation in time. These quantities are the real scalar and vector on the time-line. No mechanical quantity can be treated as a vector on the time-line. However, energy is a scalar indeed translationally invariant in time, since the potential energy is independent by hypothesis of the time. The invariance of the laws of mechanics by translation in time therefore suggests intuitively the conservation of energy.

These reasoning can obviously not be used as a proof but they show a close relation between geometry and invariance properties of a system.

9.1.4.4.4 Noether's theorem

We will now prove that Noether's (first) theorem states that every differentiable symmetry of the action of a physical system has a corresponding conservation law.

For this purpose let us consider L the Lagrangian (see section Analytical Mechanics page 3155) of a system represented by the $2n$ generalized coordinates $q_i, \dot{q}_i$ (in a space of dimension n) in the configuration space. Let us suppose that this system is invariant under the following infinitesimal transformation denoted h_s :

$$h_s(q): \quad q_i \rightarrow {q'}_i \tag{9.1.73}$$

Where s is a real number (rotation angle, translation distance, or translation time value) and continuous parameter and for which we have:

$$h_{s=0}(q) = q \tag{9.1.74}$$

The function $h_s(q)$ acts continuously on the variational path following the intellectual approach that will be stated in the section of Analytical Mechanics.

Let us suppose that the functions $q_i, \dot{q}_i$ are solutions of the Lagrange equations (which we will prove in the section of Analytical Mechanics). According to our assumptions the functions (defined):

$$\varphi(s,t) = h_s \qquad \dot{\varphi}(s,t) = \frac{\mathrm{d}}{\mathrm{d}t} h_s \tag{9.1.75}$$

are therefore necessarily also solutions of the Lagrange equations, which is translated explicitly by (we omit the indication of the sum after to make the notation more light...!):

$$\sum_i \left(\frac{\partial L(\varphi(s,t),\dot{\varphi}(s,t))}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(\varphi(s,t),\dot{\varphi}(s,t))}{\partial \dot{q}_i} \right) = 0 \tag{9.1.76}$$

Moreover, by hypothesis, the Lagrangian is invariant for the transformations of the type described by $h_s : q_i \rightarrow {q'}_i$. It follows that its derivative with respect to the parameter s is necessarily zero:

$$\frac{\mathrm{d}}{\mathrm{d}s} L(\varphi(s,t), \dot{\varphi}(s,t)) = 0 \tag{9.1.77}$$

And we will prove in the section of Analytical Mechanics (under the form of an integral being equal to zero) the relation:

$$\frac{\partial L}{\partial q_i}\delta q_i + \frac{\partial L}{\partial \dot{q}_i}\delta \dot{q}_i = 0 \tag{9.1.78}$$

which can finally be written:

$$\frac{\partial L}{\partial q_i}\delta \phi_s + \frac{\partial L}{\partial \dot{q}_i}\delta \dot{\phi}_{si} = 0 \tag{9.1.79}$$

by dividing the both sides by $\mathrm{d}s$:

$$\frac{\partial L}{\partial q_i}\frac{\mathrm{d}\varphi_i}{\mathrm{d}s} + \frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}\dot{\varphi}_i}{\mathrm{d}s} = 0 \tag{9.1.80}$$

but we also have from the Euler-Lagrange equation (see section Analytical Mechanics page 3162):

$$\frac{\partial L}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i} = 0 \Leftrightarrow \frac{\partial L}{\partial q_i} = \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i} \tag{9.1.81}$$

We then get:

$$\left(\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}\right)\frac{\mathrm{d}\varphi_i}{\mathrm{d}s} + \frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{d}\varphi_i}{\mathrm{d}s}\right) = \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}\varphi_i}{\mathrm{d}s}\right) = \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right) = 0 \tag{9.1.82}$$

So the quantity:

$$\frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s} \tag{9.1.83}$$

is a constant of the movement!

The Noether's theorem then is stated as follows:

Given a system with a Lagrangian $L(q_i, \dot{q}_i, t)$ on which we apply an infinitesimal transformation $h_s : q_i \rightarrow {q'}_s$, where s is a real and continuous parameter (angle rotation, distance translation, time value translation). Then there exist a constant of motion denoted $C({q'}_i, \dot{q'}_i, t)$ whose expression is given by:

$$\boxed{C({q'}_i, \dot{q'}_i, t) = \left(\frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right)_{s\rightarrow 0}} \tag{9.1.84}$$

in other words: every differentiable symmetry of the action of a physical system has a corresponding conservation law.

Let us apply now the Noether's theorem to the cases previously studied. Let us fix an arbitrary Cartesian reference frame of origin O. Let us write $(\vec{e}_1,\vec{e}_2,\vec{e}_3)$ the orthonormal basis of this reference frame. Let us consider a system of n particles identified in O by their position vectors $\vec{r}_i$. The Lagrangian of this system is then $L(\vec{r}_{j,i},\dot{\vec{r}}_{j,i},t)$ where $j=x,y,z$ distinguishes the spatial components of the vectors $\vec{r}_i,\dot{\vec{r}}_i$.

Let us suppose now that the system is invariant by translation of distance s along the x-axis only. The translation along that axis will be written as follows:

$$r_{x,i}(t)\rightarrow h_s(r_{x,i}(t))=r_{x,i}(t)+s(\vec{e}_x\circ\vec{e}_x) \tag{9.1.85}$$

The constant of the motion given by application of Noether theorem is then (still following the x axis):

$$C({r'}_{x,i},\dot{r'}_{x,i},t)=\left(\frac{\partial L}{\partial\dot{r}_{x,i}}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right)_{s\rightarrow 0}=\frac{\partial L}{\partial\dot{r}_{x,i}}\frac{\mathrm{d}}{\mathrm{d}s}\left(r_{x,i}(t)+s(\vec{e}_x\circ\vec{e}_x)\right)=\frac{\partial L}{\partial\dot{r}_{x,i}}\underbrace{(\vec{e}_x\circ\vec{e}_x)}_{=1}=\frac{\partial L}{\partial\dot{r}_{x,i}} \tag{9.1.86}$$

We will see in the section of Analytical Mechanics analytical that $\partial L/\partial\dot{r}_{x,j}$ is the conjugate momentum $p_{x,i}$. We conclude therefore that the conserved quantity following Noether's theorem is: $p_{x,i}$ that is to say, the total linear momentum of the system along the x axis !!!

If we did the same with the other axes, we would easily prove also the conservation of total momentum along the axes, allowing us to conclude that in the general case of an infinitesimal translation:

$$\mathrm{d}\vec{r}=s(\vec{e}_x+\vec{e}_y+\vec{e}_z) \tag{9.1.87}$$

the conserved quantity is then the total momentum of the system.

Let us suppose now that the system is invariant under rotation of an infinitesimal angle s around the z-axis. This rotation will be written (for the cross product imagine in your head what happen in the space... if you don't see let us know and we will add a figure):

$$r_i(t)\rightarrow h_s(r_i(t))=r_{x,i}(t)+s(\vec{e}_z\times\vec{r}_i(t)) \tag{9.1.88}$$

and it is therefore a vector.

And we also get:

$$C({r'}_i,\dot{r'}_i,t)=\left(\frac{\partial L}{\partial\dot{\vec{r}}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right)_{s\rightarrow 0}=\frac{\partial L}{\partial\dot{\vec{r}}_i}\circ\frac{\mathrm{d}}{\mathrm{d}s}\left(\vec{r}_i+s(\vec{e}_z\times\vec{r}_i)\right)=\frac{\partial L}{\partial\dot{\vec{r}}_i}\circ(\vec{e}_z\times\vec{r}_i) \tag{9.1.89}$$

Once again, knowing that:

$$\vec{p}_i=\frac{\partial L}{\partial\dot{\vec{r}}_i} \tag{9.1.90}$$

the conserved quantity obtained by application of Noether's theorem is therefore:

$$C({r'}_i,\dot{r'}_i,t)=\left(\frac{\partial L}{\partial\dot{\vec{r}}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right)_{s\rightarrow 0}=\vec{p}_i\circ(\vec{e}_z\times\vec{r}_i) \tag{9.1.91}$$

and we have shown in the section of Vector Calculus page 1911 that:

$$\vec{x}\circ(\vec{y}\times\vec{z})=-\vec{z}\circ(\vec{y}\times\vec{x})=-(-\vec{y}\circ(\vec{z}\times\vec{x}))=\vec{y}\circ(\vec{z}\times\vec{x}) \tag{9.1.92}$$

which brings us to write:

$$C(r'_i,\dot{r'}_i,t)=\vec{e}_z\circ(\vec{p}_i\times\vec{r}_i(t))=\vec{e}_z\circ\vec{b}_i=b_{z,i} \tag{9.1.93}$$

We prove in the same way the invariance of the Lagrangian under rotations in the other axes which leads to the conservation of the components along these axes of the total angular momentum of the system.

In conclusion, we have identified three well known different readings of the laws of physics (we omit the gauge transformations):

$$C(q'_i,\dot{q'}_i,t)=\left(\frac{\partial L}{\partial\dot{q}_i}\frac{\mathrm{d}h_s}{\mathrm{d}s}\right)_{s\to 0}$$

Observation	Conservation Law	Physical interpretation
Invariance of physics laws by translation	Conservation of momentum	Homogeneity of space: space has the same properties in all its points. $C\left(r'_{x,i},\dot{r}'_{x,i},t\right)=p_{x,i}$
Invariance of physics laws by rotation	Conservation of angular momentum	Isotropy of space: space has the same properties in all directions. $C\left(r'_{x,i},\dot{r}'_{x,i},t\right)=b_{z,i}$
Invariance of physics laws by translation in time	Conservation of energy	Homogeneity of the time: the laws of nature do not change over time. $\frac{\partial L}{\partial q}-\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}}\right)=0\Leftrightarrow\frac{\mathrm{d}L}{\mathrm{d}t}=0$

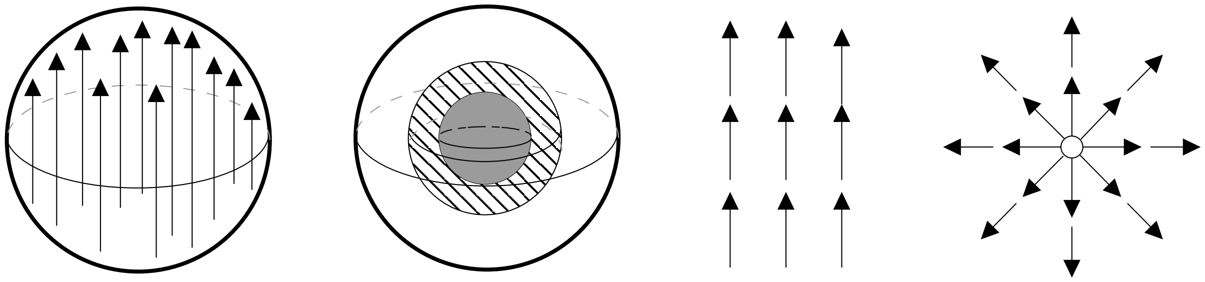
Table 9.15: **Conservation Laws**

By analogy we can see by the proofs above that momentum is to position what energy is to time (the reader must keep this information in mind for when we will discuss the Heisenberg uncertainty principle in the section of Quantum Wave Physics)!

In other words, the Universe seems to be:

P1. Homogeneous (no origin of time, or space, that is privileged) that is to say invariant under translation

P2. Isotropic (no preferred direction) that is to say invariant under rotations



homogeneous
not isotropic

isotropic
not homogeneous

homogeneous
not isotropic

isotropic
not homogeneous

Figure 9.8: Isotropic vs Homogeneous

9.1.4.5 Curie's Principle

The Curie's principle (which we owe to Pierre Curie) arises somewhat intuitively from Noether's theorem and is stated as following: If a cause has a certain symmetry or invariance, then its effect will be the same symmetry (or the same invariance), or a higher symmetry, provided that the problem of the solution is unique.

> **Remark**
>
> Note that the elements of symmetries act on the directions of the vectorial quantities, while invariance act on variables that depend on these quantities.

Thus, in a homogeneous and isotropic space, if we apply a geometric transformation to a physical system that is able to generate certain effects (forces, fields), then these effects undergo the same transformation.

In other words, if a physical system $\mathcal{S}$ has a certain degree of symmetry, then we can infer the effects generated by the system at a point from effects at another point.

Here are the 6 properties of symmetries derived from the Curie's principle:

P1. **Invariance by translation:** if $\mathcal{S}$ is invariant throughout translation parallel to an axis, the effects are independent of the coordinate axis (interest is then work in Cartesian coordinates).

P2. **Axial symmetry:** if $\mathcal{S}$ is invariant in rotation about a given axis, then its effects do not depend on the angle that defines the rotation (the interest being then to work in cylindrical coordinates).

P3. **Cylindrical symmetry:** if $\mathcal{S}$ is invariant by translation AND rotation, then its effects depend only on the distance from the axis of rotation (the interest being then to work in cylindrical coordinates).

P4. **Spherical symmetry:** if $\mathcal{S}$ invariant in rotation around a fixed point, then its effects depend only on the distance to the fixed point (the interest being then to work in spherical coordinates).

P5. **Plane of symmetry:** if $\mathcal{S}$ has a plane of symmetry, then at any point of this plane:

- an effect that has a vectorial origin is contained in the plane
- an effect that has pseudo-vector character (see the section of Vector Calculus for the definition of a pseudo-vector at page 1799) is perpendicular to the plane

P6. **Plane of antisymmetry:** if, by symmetry with respect to a plane, $\mathcal{S}$ is converted to $-\mathcal{S}$ then at any point of this plane:

- an effect that has a vectorial origin is perpendicular to the plane
- an effect that has pseudo-vector character is contained in the plane

9.1.5 Point Spaces

We have hesitated quite long to write the text below as it already partially in the section of Vector Calculus and respectively of Tensor Calculus. But finally do a summary of the main concepts of these both fields only for Classical Mechanics seems to be perhaps a good choice or at least a good reminder!

The study of physical phenomena in Classical Mechanics use initially their representation in the space of classical Euclidean geometry with one time dimension and any number of spatial dimensions.

The vectors we studied in the section of Vector Calculus (tensor of order 1) and the tensors (of any order) we studied also in the section of Tensor Calculus can as we have already mentioned, be used to connect each point in space-time to the origin of a given repository or reference frame, thereby forming vector and/or tensor fields. This mathematical fact, requires the mathematical definition of spaces formed by points also named "point spaces" or "punctual spaces".

The precise definition of punctual vector space-time that we will give will be built from the concept of vector space that we saw in the section of Vector Calculus (see page 1805).

Let us see first the particular example of the point space formed by triplets of numbers that is directly derived from the conventional three-dimensional euclidean geometrical space $\mathcal{E}^3$.

So, let us take two triplets of numbers denoted by:

$$\vec{A}=(a_1,a_2,a_3) \qquad \vec{B}=(b_1,b_2,b_3) \tag{9.1.94}$$

etc.

Let us denote by $\mathcal{E}'^3$ the set of all the elements $\{\vec{A},\vec{B},\ldots\}$ formed by triplets of numbers. At any pair $(\vec{A},\vec{B})$ of two elements of two elements of $\mathcal{E}'^3$, taken in this order (because in physics the time has a direction!!! the vectors have a given order), we can make correspond a vector $\vec{x}$ belonging to a vector space $\mathcal{E}^3$, and denoted geometrically by $\overrightarrow{AB}$ and defining this latter space by a triplet of numbers such that (we use the index notation as studied in the section of Tensor Calculus):

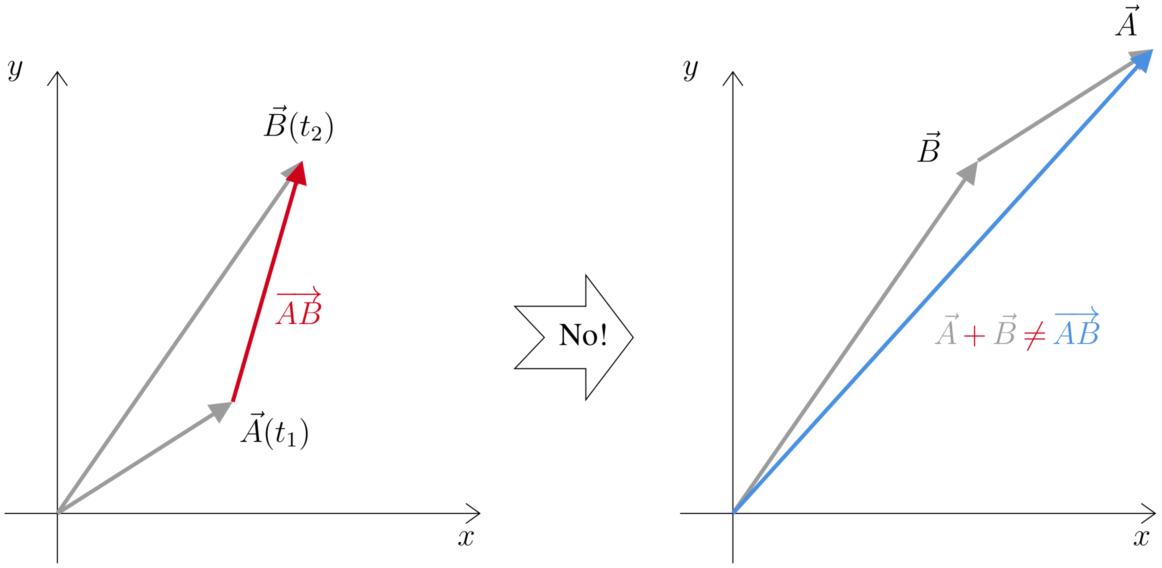
$$\vec{x}=\overrightarrow{AB}=\vec{B}-\vec{A}\Leftrightarrow x_i=b_i-a_i \tag{9.1.95}$$

with $i=1,2,3$.

We then have:

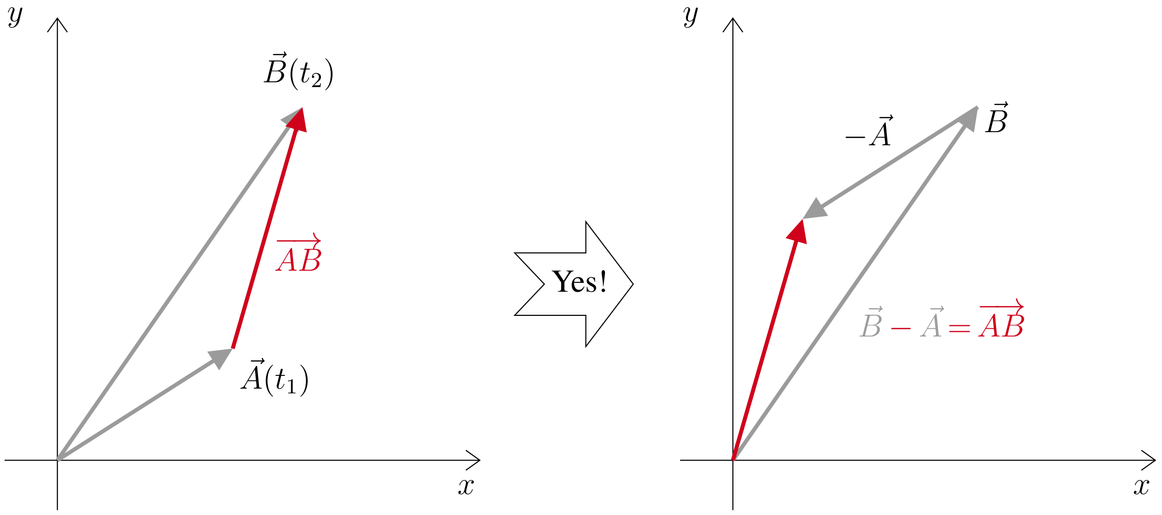
$$\vec{x}=\overrightarrow{AB}=\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix} \tag{9.1.96}$$

Indeed, the choice of this expression comes once again from the fact that for example position vectors in physics are ordered by the time t:



y
$\vec{B}(t_2)$
$\overrightarrow{AB}$
$\vec{A}(t_1)$
x
No!
y
$\vec{A}$
$\vec{B}$
$\vec{A}+\vec{B}\neq\overrightarrow{AB}$
x

But:



y
$\vec{B}(t_2)$
$\overrightarrow{AB}$
$\vec{A}(t_1)$
x
Yes!
y
$-\vec{A}$
$\vec{B}$
$\vec{B}-\vec{A}=\overrightarrow{AB}$
x

If we define relatively to this element the addition and the multiplication by a scalar, we fall back on as we have already see it in the section of Set Theory with a vector space structure.

The correspondence we thus build between any ordered pair of elements $(\vec{A},\vec{B})$ of two elements of $\mathcal{E}'^3$ and a vector of a vector space of $\mathcal{E}^3$, obviously satisfies the following properties:

P1. Antisymmetry: $\overrightarrow{AB}=-\overrightarrow{BA}$

P2. Associativity with respect to addition: $\overrightarrow{AC}=\overrightarrow{AB}+\overrightarrow{BC}$

P3. If O (an origin) is an arbitrary point chosen in $\mathcal{E}'^3$, to any vector $\vec{x}$ of $\mathcal{E}^3$, there is a point M and a unique one, such that $\overrightarrow{\mathrm{O}M}=\vec{x}$.

Mathematicians say that a space can be say to be a "point space" if and only if the associated vector space respect the previous three relations (which seems quite obvious in fact...). The elements of $\mathcal{E}^3$ are then obviously named "points".

When $\mathcal{E}^3$ is associated with a dot product (see section Vector Calculus page 1821) then we know that $\mathcal{E}^3$ will be say to be a "pre-Euclidean point space".

Let us consider any point O of a pre-Euclidean point space and base $(\vec{e}_i)$ associated with it.

Definitions (#9.1.421):

D1. We name "reference of the space" $\mathcal{E}^3$ the set consisting of the elements O (origin) and of the base $(\vec{e}_i)$. This kind of reference frame is denoted:

$$(\vec{e}_i) := (\mathrm{O}, \vec{e}_i) = (\vec{e}_1, \vec{e}_2, \vec{e}_3) \tag{9.1.97}$$

D2. The "components" or "coordinates" of a point M of a pre-Euclidean space point $\mathcal{E}^3$, relative to the reference $(\vec{e}_i)$, are the (when not specified: contravariant[8]) components x^i of the vector $\vec{x} = \overrightarrow{\mathrm{O}M}$ relatively to the base $(\vec{e}_i)$.

Given two points M and M' of say $\mathcal{E}^3$ (as in fact we know that we can choose any number n of dimensions) defined by respective (contravariant) coordinates x^i and x'^i, we then have as we know from the section Tensor Calculus:

$$\overrightarrow{\mathrm{O}M} = x^i \vec{e}_i \qquad \overrightarrow{\mathrm{O}M'} = x'^i \vec{e}_i \tag{9.1.98}$$

Using the properties P1 and P2 given above:

$$\overrightarrow{MM'} = \overrightarrow{M\mathrm{O}} + \overrightarrow{\mathrm{O}M'} = -\overrightarrow{\mathrm{O}M} + \overrightarrow{\mathrm{O}M'} = (-x^i + x'^i)\vec{e}_i \tag{9.1.99}$$

We conclude that the components of the vector $\overrightarrow{MM'}$, in the base $(\vec{e}_i)$ are the 3 quantities $(x'^i - x^i)$ (n quantities in the case of a n dimension space), differences of the contravariant coordinates of the points M and M'.

Given $(\vec{e}_i)$ and $(\vec{e'}_j)$ any two basis of $\mathcal{E}^n$ and linked by the general relations of change of basis (see sections of Tensor Calculus page 2066 and Linear Algebra page 1992 for the details):

$$\vec{e}_i = A'^k_i \vec{e'}_k \qquad \text{and} \qquad \vec{e'}_k = A^i_k \vec{e}_i \tag{9.1.100}$$

Let us seek the relations between the coordinates of a point M of $\mathcal{E}^n$ relatively to these two bases. For this, let us express the vector $\overrightarrow{\mathrm{OO'}}$ and $\overrightarrow{\mathrm{O'O}}$ on each of these bases:

$$\overrightarrow{\mathrm{OO'}} = \alpha^i \vec{e}_i \qquad \overrightarrow{\mathrm{OO'}} = \alpha'^j \vec{e'}_j \tag{9.1.101}$$

and same for the vectors $\overrightarrow{\mathrm{O}M}$ and $\overrightarrow{\mathrm{O'}M}$, thus:

$$\overrightarrow{\mathrm{O}M} = x^i \vec{e}_i \qquad \overrightarrow{\mathrm{O'}M} = x'^j \vec{e'}_j \tag{9.1.102}$$

On another part we have:

$$\overrightarrow{\mathrm{O}M} = \overrightarrow{\mathrm{OO'}} + \overrightarrow{\mathrm{O'}M} = \alpha^i \vec{e}_i + x'^j \vec{e'}_j = \alpha^i \vec{e}_i + x'^j A^i_j \vec{e}_i = \left(\alpha^i + A^i_j x'^j\right) \vec{e}_i \tag{9.1.103}$$

---

[8] As we have seen in the section of Tensor Calculus the contravariant and covariant components are the same in an orthonormal base.

Identifying the result relatively to the vector $\vec{e}_i$ in the expression of $\overrightarrow{\mathrm{O}M}$, we have:

$$\boxed{x^i=\alpha^i+A^i_jx'^j} \tag{9.1.104}$$

And in an analogue way:

$$\boxed{x'^j=\alpha'^j+A'^j_ix'^i} \tag{9.1.105}$$

These two relations are more than useful in physics where we often have to consider a base in a given reference frame (so we can express the position of a point from either one or the other using these relations).

Let us now consider a pre-Euclidean point space as well as M and M' two points of this space. We have proved in our study of Topology (see section Topology page 2450) that the norm of the vector $\overrightarrow{MM'}$ is a possible measure of the distance between M and M' respecting some interesting and useful axioms. So we have if we denote by y_i the covariant components of $\overrightarrow{MM'}$:

$$\overline{MM'}=||\overrightarrow{MM'}||=\sqrt{\sum_i y_i^2} \tag{9.1.106}$$

If the both points M and M' have respectively for contravariant coordinates x^i and x'^i with respect to a base $(\vec{e}_i)$, we know following our definition above in the case of ordered vectors that:

$$\overrightarrow{MM'}=(-x^i+x'^i)\vec{e}_i \tag{9.1.107}$$

The squared norm is given as we have seen in our study of Tensor Calculus (see section Tensor Calculus page 2051) by the more general explicit relation:

$$||\overrightarrow{MM'}||^2=g_{ij}(x'^i-x^i)(x'^j-x^j)=g_{ij}\Delta x^i\Delta x^j \tag{9.1.108}$$

If we denote by $\mathrm{d}s$ the distance between the points M and M'. The above relation provides the expression of the square of the distance between these two points in the form:

$$\boxed{\mathrm{d}s^2=g_{ij}\mathrm{d}x^i\mathrm{d}x^j} \tag{9.1.109}$$

Let us also recall (see section Tensor Calculus page 2051) that for a pre-Euclidean point space where the basis vectors are orthonormal, we have:

$$g_{ij}=\delta_{ij} \tag{9.1.110}$$

and the expression of the distance becomes:

$$\mathrm{d}s^2=\mathrm{d}x^i\mathrm{d}x^j=\mathrm{d}x_i\mathrm{d}x_j \tag{9.1.111}$$

We thus get wan expression that generalizes to n dimensions, the square of the elementary distance, relatively to an orthogonal Cartesian coordinate system in the space of classical geometry (Euclidean).

The vectors in physics are generally functions of one or more variables, they may be variables of space or time. When to a point M of a point space $\mathcal{E}^n$, we attach a tensor, defined by its components relatively to the base $(\vec{e}_i)$, we say that we have given ourselves a "tensor field" (the tensor fields of order 1 being the vector fields as we have seen it in the section of Tensor Calculus).

For n-dimensional vectors, the concept of derivative from a three-dimensional vector is generalized and we get all the classic relations relatively to derivatives[9].

Let us consider a vector $\vec{x}$ belonging to a pre-Euclidean space $\mathcal{E}^2$ whose components on a base $(\vec{e}_i)$ are functions of some parameter α (typically the time). We will denote this vector $\vec{x}(\alpha)$ and we will have:

$$\vec{x}(\alpha)=x^i(\alpha)\vec{e}_i \tag{9.1.112}$$

By definition, the derivative from the vector $\vec{x}$ relatively to the component α is a vector denoted:

$$\vec{x}\,'(\alpha) \tag{9.1.113}$$

following the notation of most mathematicians. Or:

$$\dot{\vec{x}}(\alpha) \tag{9.1.114}$$

following the tradition of some physicists. Or even:

$$\mathrm{d}_\alpha\vec{x}(\alpha) \tag{9.1.115}$$

that we see most of time with engineers. Or more explicitly if we respect the pure mathematical notations:

$$\dfrac{\mathrm{d}\vec{x}}{\mathrm{d}\alpha} \tag{9.1.116}$$

In this textbook, we switch to a notation to another without prior notice depending on the desire and obviously to simplify the notation (the reader will have to do with it).

Since we are doing more mathematics than physics, let us write just now explicitly:

$$\vec{x}\,'(\alpha)=\dfrac{\mathrm{d}x^i(\alpha)}{\mathrm{d}\alpha}\vec{e}_i \tag{9.1.117}$$

Recalling (see section Differential and Integral Calculus page 1464) that the differential is given by:

$$\mathrm{d}\vec{x}=\vec{x}\,'(\alpha)\mathrm{d}\alpha \tag{9.1.118}$$

The different expressions of the derivatives of three-dimensional vectors relatively to the sum of vectors,dot product of two vectors are easily transferable to the case of n-dimensional vectors.

---

[9] A vector derivative - like the gradient, divergence, laplacian, etc. - is a derivative taken with respect to a vector field. Vector derivatives are extremely important in physics, where they arise throughout fluid mechanics, electricity and magnetism, elasticity, and many other areas of theoretical and applied physics

If a vector $\vec{x}$ of $\mathcal{E}^n$ depends on several independent parameters, α, β, γ, the partial derivative of $\vec{x}(\alpha,\beta,\gamma)$ vector with respect to the variable α, for example, is a vector denoted:

$$\frac{\partial\vec{x}}{\partial\alpha} \qquad \text{or} \qquad \partial_\alpha\vec{x} \tag{9.1.119}$$

whose components are the partial derivatives of the components of $\vec{x}$, namely:

$$\frac{\partial\vec{x}}{\partial\alpha}=\frac{\partial x^i}{\partial\alpha}\vec{e}_i \tag{9.1.120}$$

The total differential of the vector $\vec{x}(\alpha,\beta,\gamma)$ being written (see section of Differential and Integral Calculus page 1466):

$$\mathrm{d}\vec{x}=\frac{\partial\vec{x}}{\partial\alpha}\mathrm{d}\alpha+\frac{\partial\vec{x}}{\partial\beta}\mathrm{d}\beta+\frac{\partial\vec{x}}{\partial\gamma}\mathrm{d}\gamma \tag{9.1.121}$$

In a bases $(\vec{e}_i)$ we will consider as obvious that if a vector $\vec{x}$ is dependent of a parameter α, that its associated point M such that $\vec{x}=\overrightarrow{\mathrm{O}M}$ is also dependent of α. So if $\vec{x}$ admits a derivative, it is also same of $\overrightarrow{\mathrm{O}M}$!

Theorem 9.1. The derivative $\vec{x}\,'(\alpha)$ of a vector $\vec{x}$ does not depend on the (static) origin point O of the base but only of the considered point M.

Proof 9.1.1. Indeed, if O′ is another point of origin, we have:

$$\overrightarrow{\mathrm{O}M}=\overrightarrow{\mathrm{OO}'}+\overrightarrow{\mathrm{O}'M} \tag{9.1.122}$$

and since the vector $\overrightarrow{\mathrm{OO}'}$ is fixed and does not depend on α, we have:

$$\frac{\mathrm{d}\overrightarrow{\mathrm{OO}'}}{\mathrm{d}\alpha}=\vec{0} \tag{9.1.123}$$

hence:

$$\boxed{\frac{\mathrm{d}\overrightarrow{\mathrm{O}M}}{\mathrm{d}\alpha}=\frac{\mathrm{d}\overrightarrow{\mathrm{O}'M}}{\mathrm{d}\alpha}=\vec{x}'(\alpha)} \tag{9.1.124}$$

■ Q.E.D.

We can write the derivative of the vector $\overrightarrow{\mathrm{O}M}$ by only mentioning the point M as it is the usage in physics and therefore write:

$$\vec{x}\,'(\alpha)=\mathrm{d}_\alpha\vec{x}=\frac{\overrightarrow{\mathrm{O}'M}}{\mathrm{d}\alpha}=\frac{\vec{M}}{\mathrm{d}\alpha}=\vec{M}'(\alpha)=\mathrm{d}_\alpha\vec{M} \tag{9.1.125}$$

The differential of $\overrightarrow{\mathrm{O}M}$ is then written:

$$\mathrm{d}\vec{M}=\vec{M}\,'(\alpha)\mathrm{d}\alpha \tag{9.1.126}$$

If a point M of $\mathcal{E}^n$ is associated, relatively to base $(\vec{e}_i)$, to a vector $\vec{x}(\alpha,\beta,\gamma)=\overrightarrow{\mathrm{O}M}$, the partial derivatives of $\overrightarrow{\mathrm{O}M}$ will depend only of the point M and we will write, for example:

$$\frac{\partial \vec{x}}{\partial \alpha}=\frac{\partial \vec{M}}{\partial \alpha} \tag{9.1.127}$$

To simplify the expressions of total partial derivatives of the functions dependent of n independent variables we use, when the context permits, the index-based notations as seen in the section of Tensor Calculus. Therefore:

$$f(x,y,z,\ldots,t)=f(x^1,x^2,\ldots,x^n) \tag{9.1.128}$$

for a function f dependent of n independent variables x^n (this includes the time in physics). There partial derivatives are written into the form:

$$\partial_i f=\frac{\partial f}{\partial y^i} \tag{9.1.129}$$

The second partial derivatives with respect to the variables y^i and y^k will be written:

$$\partial_{ik} f=\frac{\partial f}{\partial y^i \partial y^k} \tag{9.1.130}$$

When $\vec{x}$ is a vector such that $\vec{x}=x^i\vec{e}_i$ whose components are dependent of n independent variables y^k such that:

$$x^i=x^i(y^1,y^2,\ldots,y^n) \tag{9.1.131}$$

the partial derivatives of the vector will then be written, using the summation convention:

$$\frac{\partial \vec{x}}{\partial y^k}=\partial_k\vec{x}=\partial_k\left(x^i\vec{e}_i\right)=(\partial_k x^i)\vec{e}_i \tag{9.1.132}$$

The concept of space-time being now introduced, we can now proceed to study the Lagrangian formalism and determining the mathematical formulation of the principle of least action (see next section).

9.2. Analytical Mechanics

ANALYTICAL MECHANICS is a reformulation of Classical Mechanics that we due the present form, also named "Lagrangian mechanics", from the work of Bernoulli brothers and especially Euler and Lagrange. It is indeed in 11696 (holocene calendar) that began the story of the true theoretical physics.

In fact, the analytical mechanics starts from the event from the following observation (in the 117th century according to holocene calendar): Any conservative system seems to move from one state to another still using the simplest means and maintaining a constant magnitude between the two states.

Remarks

R1. The above means can be: the shortest path, the fastest path (that is to say the spatio-temporal paths with lower amplitudes...).

R2. According to the first fundamental principle of physics, the constant quantity is selected as being the total energy.

This statement is named in the context of the Mechanics the "principle of least action (of Maupertuis)" or as part of general physics "variational principle" or sometimes as part of optics "principle of economy" or "Fermat's principle". In the purely mathematical abstraction framework we speak of "Hamilton's principle".

More technically, it is also formulated as follows: A system moves from one configuration to another so that the variation of the action (see below for details) between the natural path actually followed and any infinitely close and virtual trajectory having the same starts and ends in space and time is zero.

In fact, although this statement may seem as consistent, it raises doubts ... but we will see that:

1. In Classical Mechanics we can prove the Newton's first law by admitting this principle as true and by superimposing the principle of conservation of energy[10] and we can therefore also explain the wobbling motion of almost any simple solid.
2. In Electromagnetism, we will find back all the Maxwell equations (verbatim the Biot-Savart law, the Faraday law, the Lorentz force, the Laplace force, etc.) from the properties of the principle of least action and energy conservation.
3. In Optics, we will prove that the path followed by the light is always the shortest and this will allow us to prove Fermat's principle underlying any geometrical optics. Also in

---

[10] It is strongly advised that the reader remembers the situation where this principle doesn't apply as seen during our study of Noether's theorem (see page 3136)!

General Relativity this same assumption will take us to prove the deflection of light near massive bodies.

4. In Atomic Physics, the properties of the principle of least action will allow us to determine some mathematical properties of atoms and other particles (fermions and bosons in quantum field theory).

5. The principle of least action will also enable us to prove that all bodies, with or without mass, is deflected by a field of acceleration and ... so will give us the opportunity to determine the Einstein Field Equations that are the basis of the section on General Relativity (see page 5720).

6. This principle also applies to get powerful results in geometry as we shall see a little further. Thus, the analytical mechanics techniques are very intimately related to pure mathematics.

7. We can merge all of our actual knowledge of electromagnetism, quantum physics and gravitation in a single formulation (obviously long ...) using the Lagrangian formalism.

It needless to say that through this small examples the huge applications of this principle!!!

Historically, it is interesting to know that this is Pierre-Louis Moreau de Maupertuis who first articulated the principle of least action in shortly scientific form. The intervention of Euler and Lagrange in this area has been to put this principle into a mathematical form and to prove that it follows from a simple mathematical property of optima of continuous functions. It is needless to say that this latter fact that allowed to re-prove all the laws of classical physics from only pure mathematical concepts has upset at this time some people... (and still do today!).

This principle was (and always has) a significant impact and the problem was to apply the mathematical expression of the latter to all physical phenomena that had already been experimentally demonstrated and empirically at that time. Perform this proof was similar to explain why such phenomenon or such law was thus rather than otherwise. Imagine!

For example given locality, Lorentz invariance (see section Special Relativity page 5639) and know physical data since 11860 (holocene calendar) it can be shown that the Lagrangian describing all observed physical process (without gravity) can be written:

$$

\end{gathered}
$$

Thus, as far as we know, it seems that the first to tackle the problem was the Bâlois (Switzerland) Leonhard Euler. But we have also kept the name of Lagrange (hence the expression "Lagrangian formalism") to define the entire method and the mathematical formalism built around the principle of least action.

In fact we will see in the section the differences between:

1. Newtonian Mechanics (or Newtonian Formalism)
2. Lagrangian Mechanics (or Lagrangian Formalism)
3. Hamiltonian Mechanics (or Hamiltonian Formalism)

and we will see that 1 is a special case of 3 which is a special case of 2. We will also prove with in some context (as quantum physics) the Hamiltonian is sometimes preferred to the Lagrangian and vice versa.

9.2.1 Lagrangian formalism

Classical Mechanics can be formulated in different ways. The most common is the formulation of Newton, which uses the concept of force (see section Classical Mechanics page 3199). It is by far the easiest when it comes to consider a specific issue and that's why this is the one that is taught in small classes. But to treat more complex problems or more precisely and to be able to do rigorous proofs the Newton formulation is not the most practical one!

Analytical Mechanics, initiated in the 118th century (holocene calendar), regroups therefore very different mathematized formulations of Classical Mechanics, including Hamiltonian and Lagrangian mechanics (all these formulations are equivalent!).

This formulation is taught only a little bit in small schools because we must admit the Lagrangian and Hamiltonian formalism (therefore containing the principle of least action in mathematical form) uses an abstraction level a bit higher than the normal methods and despite being often of great help in the development of theories (basic physics, Quantum Physics, General Relativity, Quantum Field Theory, Superstring Theory), it rarely follows new discovers from it (but rather useful and powerful reduction and validation method).

Let's begin our work:

9.2.1.1 Generalized coordinates and frames

A natural reflex usually leads to refer to the position of a point in space with the only knowledge of its three Cartesian coordinates x, y, z (or polar, cylindrical, spherical, etc.). This attitude is also often justified by the simplicity of a lot of situations encountered in practice where it is not necessary to search for more elaborate methods or to go in other coordinate systems (see section Vector Calculus page 1846).

To locate the position of a mobile (or a material point) in physics it is necessary at first to associate a frame to the repository. Thus, a "frame" is a system (concrete physical) of location (or "reference system") in the space associated with the repository.

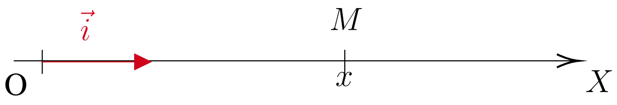
✍**Examples:**

E1. In astronomy, for many problems, the Earth is taken as repository, but on the center of it we put the reference frame (most of time in spherical coordinates).

E2. In mechanics a body is taken as a repository but it is on its inertial center is that we put the reference frame.

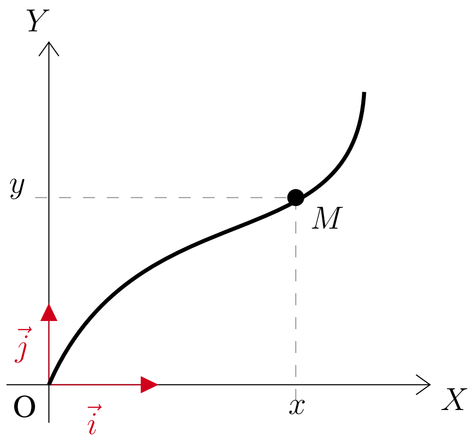
Conventional frames in Classical Mechanics are mostly canonical oriented pre-Euclidean spaces basis (see section Vector Calculus page 2051) and where each point or each vector of the space, can be represented algebraically by its affixes values (the value in the ordinate corresponding to the projection on the vertical axis) and its abscissas values (corresponding to the projection on the horizontal axis).

Here are some trivial examples:



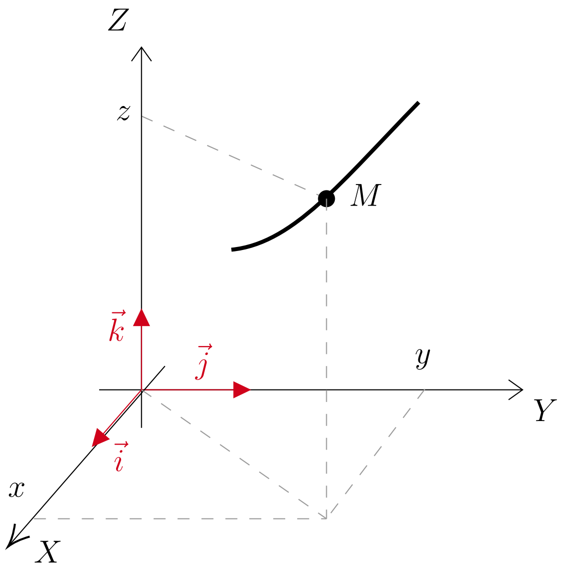
One dimensional reference frame

The motion of M is done along a straight line



Two dimensional reference frame
(Argand-Cauchy plane)

The motion of M is done in the plane or in a subset of it



Three dimensional reference frame

The motion of M is done in the space or in a subset of it

Figure 9.10: **Movements in referential frames from to 1, 2 or 3 dimensions**

Definitions (#9.2.422):

D1. A repository, assimilated to a reference frame, is said to be a "Galilean reference frame" (it's rare that we make explicit mention of in physics for lack of rigour) if:

- We can consider it as motionless during the study of the movement of the system or to be in an uniform rectilinear translation relative to another repository itself motionless (this is also named an "inertial reference frame" because not accelerated).

  So if we neglect the rotational movement of the Sun (actually a G2V-type star, aka yellow dwarf) around the center of the galaxy, then the heliocentric reference frame may be regarded as a Galilean reference frame. If we neglect the rotational movement of the Earth around the Sun (actually a G2V-type star, aka yellow dwarf), then the geocentric reference may be regarded as a Galilean reference frame. If we neglect the rotational motion of the Earth itself, then the terrestrial reference frame can be considered as Galilean. In many mechanical experiments on the surface of the Earth, we find that the terrestrial reference frame can be considered as Galilean with very good accuracy for short time experiments. Fortunately there are still a lot of phenomena which must take into account the rotation of the Earth (deviation to the East, Foucault pendulum, etc.)

- We can consider it as a system in which Newton's laws are satisfied (see section Classical Mechanics page 3199).

D2. A repository, assimilated to a reference frame, is named "barycentric reference frame" (see section Euclidean Geometry page 2635) if it has for origin the center of mass (see section Classical Mechanics page 3213) of the body being studied.

Therefore, the "Copernicus reference frame" is assimilated to the center of gravity (inertia) of our Solar System, the "heliocentric reference frame" also named "Kepler's reference frame" to the Sun center of mass.

D3. A repository, assimilated to a reference frame, is named "geocentric reference frame" when we make reference to a system of axes placed at the center of mass of the Earth. The axes, parallel to those of a Copernicus reference frame, point in the direction of to three fixed stars. In this reference the Earth rotates on itself in 24h.

D4. A repository, assimilated to a reference frame, is named "Terrestrial reference frame" when we make reference to a system of axes placed at the center of mass of the Earth that has a uniform rotational movement corresponding to the speed of rotation of the Earth. Traditionally one of the axes is directed to the pole star. This is the reference frame that we refer to as in real life (it is not strictly speaking a Galilean reference frame)! This will induce specific effects on the movements in the atmosphere such as we experience them.

Remarks

R1. In the 2-dimensions case, say that an orthonormal basis $(\mathrm{O},\vec{i},\vec{j})$ is a "direct reference frame" means that the oriented angle of $(\vec{i},\vec{j})$ has for main value $\pi/2$ (clockwise). Say that an orthonormal basis $(\mathrm{O},\vec{i},\vec{j})$ is an "indirect reference frame" means that the angle has for main value $-\pi/2$. In all what will follow, if we do not specify the orientation, this suggests that $(\mathrm{O},\vec{i},\vec{j})$ is a direct reference frame.

R2. Obviously, there are a number of arbitrary choices to make when we set up a reference frame: for example, where to place the origin of the spatial coordinates, how to orient the axes, and where to put the origin of time. But this freedom is not a real issue, indeed if we make a choice, there are mathematical techniques (see section Linear Algebra page 1992) that can be used to move from an old system (basis) to a new one.

It is true that the three parameters x, y, z are perfectly sufficient to identify a material point in ordinary space as we have already mentioned it in our study punctual spaces (see section Principles page 3145), but nevertheless it is sometimes inevitable, or just more advantageous to use a larger number of parameters than three. We can obviously consider all sorts of settings to achieve the coordinates of a point in space, so that in a more generalized manner we shall have to take into account relation of the type (we do not keep the same writing that the one we had in our study punctual spaces for consistency with the many existing references on the subject):

$$\begin{aligned} x&=x^1=x^1(q^1,q^2,\ldots,q^n)\\ y&=x^2=x^2(q^1,q^2,\ldots,q^n)\\ z&=x^3=x^3(q^1,q^2,\ldots,q^n) \end{aligned} \tag{9.2.1}$$

The parameters $q^1, q^2, \ldots, q^n$ are named "generalized coordinates" and are the parameters to which a problem will most often referred. Knowing their expression over time is a fundamental problem of dynamics (think for example a satellite which coordinates x, y, z are dependant on spherical components φ, θ, r that are themselves depending of the time t). This means that we will have reach a solution when we will have the independent relation:

$$\begin{aligned} q^1 &= q^1(t) \\ q^2 &= q^2(t) \\ &\ldots \\ q^n &= q^n(t) \end{aligned} \tag{9.2.2}$$

Geometrically these components can be lengths along straight lines, or arc lengths along curves, or angles; not necessarily Cartesian coordinates or other standard orthogonal coordinates. There is one for each degree of freedom, so the number of generalized coordinates equals the number of "degrees of freedom", n. In physics a "degree of freedom" corresponds to a quantity that changes the configuration of the system, for example the angle of a pendulum, or the arc length traversed by a bead along a wire, etc.

It is therefore important to notice that the number of parameters q^i defining locating a point in space is at least equal to three in most common cases. It is ultimately the nature of the envisaged situations that suggest the choice of the number of parameters to be used (cartesian coordinates, cylindrical, spherical, ...).

The vector:

$$\vec{q}(t) = (q^1(t), q^2(t), \ldots, q^n(t)) \tag{9.2.3}$$

is a point in the "configuration space" of the system.

Indeed, it is quite natural mathematically speaking to associate the manipulation of the n generalized coordinates q^i to a n-dimensional space, in which the q^i would appear as the coordinates of a point P representative of the configuration of any system. This is why we name this space the "configuration space" and is denoted $\mathcal{C}^n$.

But the rigour of mathematical-physical, brings us to provide a more accurate description of the phenomena by adding the important variable that is the time, often seen as independent variable in the q^i. We thus arrive inevitably to use another configuration space $\mathcal{C}^{n+1}$ that we name "event space".

This configuration space is of great interest to many problems of modern science and is particularly well suited to the relativistic problems. The independent variables constituting the spatial and temporal coordinates then form what we name the "Euler variables" (as we will see later, they have this name because we can find them in the Euler-Lagrange equation).

The components $x^1, x^2, \ldots, x^n$, that can be seen as functions as we have just see, will be assumed now defined, continuous, of class $\mathcal{C}^2$ (to work with the acceleration) relatively to the parameters $q^1, q^2, \ldots, q^n$ and will lead to a Jacobian different from zero (see section Differential and Integral Calculus page 1524).

Definitions (#9.2.423):

D1. A "holonomic constraint" is a constraint equation of the following shape for a particle:

$$f(x^1,x^2,x^3,t)=f(\vec{x},t)=0 \tag{9.2.4}$$

which connects all the 3 spatial coordinates of that particle together, so they are not independent and founding such a function can help to solve the study of a dynamic system.

D2. A mechanical system can involve constraints on both the generalized coordinates and their derivatives. Constraints of this type are known as "non-holonomic constraint" and are of the form:

$$f(q^1,\ldots,q^n,\partial_t q^1,\ldots,\partial_t q^n,t)=f(\vec{q},\dot{\vec{q}},t)=0 \tag{9.2.5}$$

To study continuum medium (radically different concept from a material point), we will have however two different approaches:

1. The Lagrange method or Hilbert Method: we seek to characterize the movement of the medium described by a Lagrangian formulation consisting in characterizing it by a system of equations in the Newtonian sense. For derivatives, we the have the speed and acceleration of the medium.
2. The Euler method: Instead of following the path of a point, we focus on the evolution of a physical characteristics at a given point as the speed, temperature acceleration, pressure or other. We speak so often of "Eulerian system".

9.2.1.2 Variational Principle

A "variational principle" is a scientific principle used within the calculus of variations, which develops general methods for finding functions which extremize the value of quantities that depend upon those functions. For example, to answer this question: « *What is the shape of a chain suspended at both ends?* » we can use the variational principle that the shape must minimize the gravitational potential energy.

The "variational principle" is thus only the contemporary mathematical form of the principle of least action, which, as we have already mentioned, is at the base of the Lagrangian formalism and of all physics!

Let us recall that according to the statement of the variational principle we must find in any physical phenomenon, an amount that is naturally optimized (minimized or maximized) and describing all the variables of the system studied and thus its outcome.

Here are the steps that we will follow and once this approach presented, we will address its mathematical formalization.

The proposals are the following:

P1. We assume the variational principle and the principle of conservation of energy as correct.

P2. The total energy of a closed system is constant and consists only of the summation of the kinetic energy and potential energy.

If we consider only kinetic energy, then the system is named "free system"; if both energies are considered, then we say that the system is a "generalized system".

P3. We define a mathematical function (whose variables are the generalized coordinates) named "Lagrangian" which is given by the difference of the two previous mentioned energies.

P4. On the evolution of a system between two states, we seek for the properties of the function (Lagrangian) that minimize the variation of the difference of the two energies on temporal or metric evolution of the system.

So to put it in a mathematical form, we first ask that there is a real function of $2n$ variables (the n general coordinates and the corresponding n derivatives to the implicit variable that will typically be in physics the time t):

$$(q_1,\ldots,q_n,\dot{q}_1,\ldots,\dot{q}_n)\mapsto L(q_1,\ldots,q_n,\dot{q}_1,\ldots,\dot{q}_n) \tag{9.2.6}$$

that we will name "generalized Lagrangian" of the system, whose integral satisfies the following statement:

In a natural movement starting from a point $A(q_1^A,\ldots,q_n^A)$ at the time t_A, arriving at the point $B(q_1^A,\ldots,q_n^A)$ at the time t_B, the following integral (that is a pillar of modern physics!!!!!) is named "action integral" or simply "action":

$$S(q,\dot{q})=\int_{t_A}^{t_B} L[q_1(t),\ldots,q_n(t),\dot{q}_1(t),\ldots,\dot{q}_n(t)]\mathrm{d}t \tag{9.2.7}$$

which may also be denoted more shortly:

$$S(q,\dot{q})=\int_{t_A}^{t_B} L(q,\dot{q})\mathrm{d}t \tag{9.2.8}$$

must be an extremal value (in fact, a "minimum" or "maximum"), since we could as well take $-L$ instead of $+L$ in the choice of the definition of the generalized Lagrangian).

This "action" or "Lagrangian's action" S is what we commonly name in physics a "functional" and has units of energy multiplied by time since L is energy, or said otherwise: mass × velocity × distance, or formally $S_0=m\cdot v\cdot\ell$.

It was Maupertuis that proposed this new metric based on its comprehensions of shortest time problem in Mechanics (leading to the brachistrone) and in Optics (leading to Snell's law).

The faster it goes, the greater the action. And if it's a particle, then the more massive it is, the greater the action. If there are multiple segments to the journey, then the total action is just the sum of the mass times velocity times distance for each segment:

$$S_0=\Sigma m\cdot v\cdot\ell \tag{9.2.9}$$

In 11744 (holocene calendar), Maupertuis wrote: «*This action is the true expense of Nature, which she manages to make as small as possible*».

Maupertuis was attacked and ridiculed by some people with this idea coming from nowhere.

But there was one man who vehemently defended it, and that man was Leonhard Euler. The first thing Euler did was he replaced the sum with an integral:

$$\sum mv\ell \rightarrow \int mv\mathrm{d}\ell \tag{9.2.10}$$

so we could calculate the action while speed or direction changed continuously. And he used this to find the path of a particle around a central mass, like the orbit of a planet around a star.

Solving this meant that out of every possible path between two points, Euler would have to find the one for which the action was the smallest. This is similar to the problem Fermat tried to solve, only now, instead of changing one variable, he would have to vary every possible point along the path, which is infinitely many. Needless to say, this was an arduous task.

Math had not yet developed the tools required to handle such problems. Fortunately, Euler himself invented a new method. It was clunky and time consuming, but it worked.

Through this process, he realized that the principle of least action only works if the total energy is conserved, and it is the same for all paths considered. These were two conditions that Maupertuis hadn't realized were necessary. So Euler improved the mathematical rigor of the principle.

But Euler was still far from a general proof. That would have to wait for another legendary mathematician, Joseph-Louis Lagrange.

Joseph-Louis Lagrange was a shy 19-year-old, mostly self-taught. But despite his age, he was already working at the forefront of mathematics, including with Euler's new method. In 11754 (holocene calendar), he shared his results with Euler, who replied that Lagrange had « *extolled the theory to the highest summit of perfection*». But besides being world class mathematicians, the two had another thing in common. They were both huge proponents of the principle of least action. And around five years later, just a year after Maupertuis' death, Lagrange succeeded in providing a general proof!

9.2.1.3 Euler-Lagrange Equation

The principle of least action therefore states that the (integral) S is extremal if:

$$t \mapsto [q_1, \ldots, q_n, \dot{q}_1, \ldots, \dot{q}_n] \tag{9.2.11}$$

is the natural trajectory actually followed by the physical system.

Let us consider then a very similar trajectory to the previous, that we will denote by:

$$(q_1 + \delta q_1, \ldots, q_n + \delta q_n, \dot{q}_1 + \delta \dot{q}_1, \ldots, \dot{q}_n + \delta \dot{q}_n) \tag{9.2.12}$$

That is to say that for every i we put:

$$\begin{aligned} q_i(t) &\rightarrow q_i(t)+\delta q_i(t) \\ \dot{q}_i(t) &\rightarrow \dot{q}_i(t)+\delta \dot{q}_i(t) \end{aligned} \tag{9.2.13}$$

with:

$$\delta q_i(t_A)=\delta q_i(t_B)=0 \tag{9.2.14}$$

to ensure that we always start from the same point A to reach the same point B. The perfect determination of the extreme points (characterized by variations of a path to another one identically zero) is a major assumption of the principle of least action!

Remark

Now we will omit writing the time arguments to facilitate the notations.

If $S(q,\dot{q})$ is indeed the evolution of a system evolving following the principle of least action, then the action given by the variation:

$$\delta S := S(q+\delta q,\dot{q}+\delta\dot{q})-S(q,\dot{q}) \tag{9.2.15}$$

is zero for δq and $\delta\dot{q}$ going toward zero (meaning that any physical system returns to its original state without external intervention).

Which brings us to write:

$$\delta S=\int\limits_{t_A}^{t_B} L(q+\delta q,\dot{q}+\delta\dot{q})\mathrm{d}t-\int\limits_{t_A}^{t_B} L(q,\dot{q})\mathrm{d}t=\int\limits_{t_A}^{t_B}[L(q+\delta q,\dot{q}+\delta\dot{q})-L(q,\dot{q})]\mathrm{d}t=0 \tag{9.2.16}$$

This allows us to justify the name of "variational principle" (also sometimes named the "principle of stationarity of action"):

$$\delta S=\delta\int\limits_{t_A}^{t_B} L\mathrm{d}t=\int\limits_{t_A}^{t_B}\delta L\mathrm{d}t \tag{9.2.17}$$

This principle states that the path of a particle (or a more general system) is obtained by requiring a certain functional S named "action" is stationary relative to a infinitesimal variation of the trajectory. In other words, if we make an infinitesimal variation of the trajectory, the change must be almost zero:

$$\boxed{\delta S=\delta\int\limits_{t_A}^{t_B} L\mathrm{d}t=\int\limits_{t_A}^{t_B}\delta L\mathrm{d}t=0} \tag{9.2.18}$$

A single, simple rule that underpins all of physics, encompassing every principle from Classical Mechanics to Electromagnetism, Quantum Theory, and General Relativity, as well as the fundamental particles that make up matter!

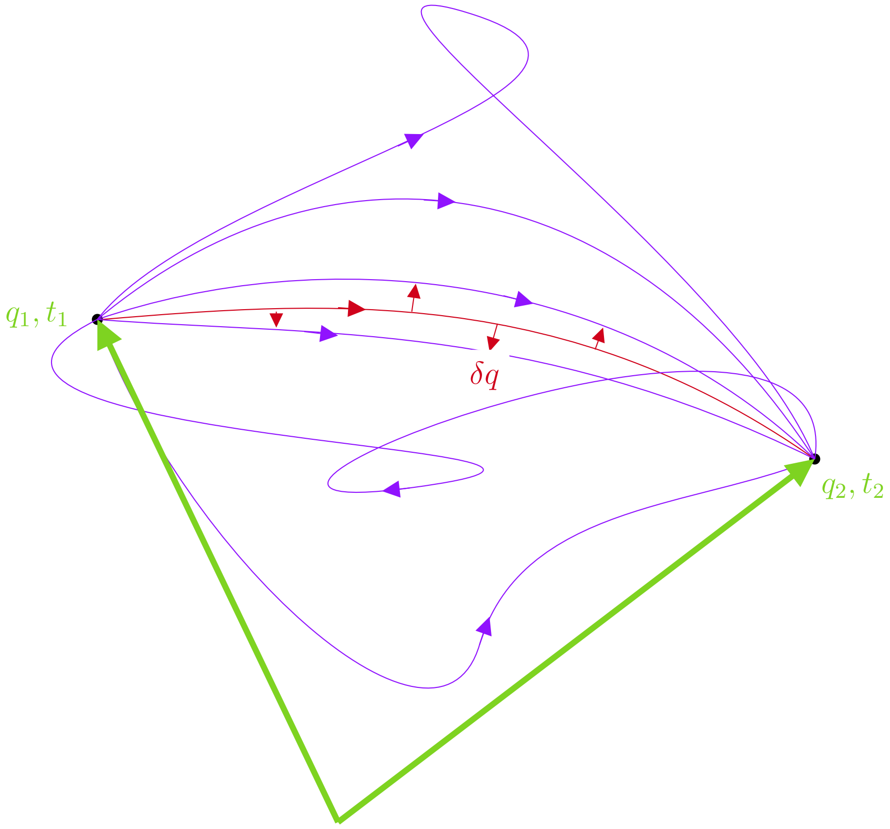


Figure 9.11: **Variation idea of Least Action Principle**

For a simple mechanical system, the action is therefore by evidence, by the principle of conservation of energy equal to the integral on the trajectory of (by definition of the Lagrangian) the difference between the kinetic energy and potential energy.

If you want to slide a mass from point A to point B, what shape of ramp will get it there the fastest? This is known as the "problem of fastest descent". Most people not educated to science will answer that fastest descent is a straight line from A to B. But if you bend the ramp down a bit at the beginning, well, the mass accelerates to a higher speed earlier. So even though it travels slightly farther, it travels faster and beats the straight ramp.

So the question is, what shape provides the perfect balance of acceleration and path length to minimize travel time? According to Galileo, it was the arc of a circle. He showed that this is faster than any polygon.

But is it the fastest? Nearly sixty years later, in June of 11696 (holocene calendar), Johann Bernoulli set this problem as a challenge to the best mathematicians in the world (mainly because he's a big show off and he wants to show that he's better than all of them). He gave everyone six months to come up with solutions, but none were submitted. So Gottfried Leibniz, a friend of Bernoulli's, persuaded him to extend the deadline to give foreigners a chance. We may think Isaac Newton was probably the intended target because everybody thought of him as the best, and so Johann would have wanted to show that he was better than Newton.

Isaac Newton was no longer a really active mathematician or physicist. He was working as the warden of the Mint, like a big high government position and on the 29th of January, 11697 (holocene calendar), Newton returned home after a long day at work to find Bernoulli's challenge in the mail.

Irritated, he wrote, «*I do not love to be dunned and teased by foreigners about mathematical things*». But the problem was too enticing, so Newton spent the rest of the day and night on it, and by 4:00 a.m. He had come up with a solution, something that took Bernoulli two weeks. Newton submitted his solution to the journal *Philosophical Transactions of the Royal Society of London* (see [414]). He sent his solution there but didn't sign it.

And Johann Bernoulli, after seeing the solution, is alleged to have said, «*I recognize the lion by his claw*». Who else could give such a solution (see page 3433).

And while overall Newton dominated Bernoulli, in this instance, Bernoulli's solution actually was much more elegant and interesting than Newton's.

How does light travel from one place to another? This was contemplated by Hero of Alexandria in the 101st century (according to holocene calendar). He realized that in a single medium, like air, light always follows the shortest path.

A consequence is that when light reflects, say, off a lake, the angle of incidence is always equal to the angle of reflection. Any other path between the start and end points would be longer. But when light goes from one medium into another, like from air into water, it bends in a peculiar way. So what is the guiding principle here?

Well, over the next 1,600 years people slowly figured out that the sine of the angle of incidence divided by the sine of the angle of refraction is equal to a constant, n, which depends on the nature of the two media. This came to be known as "Snell's Law" (see section Optics page pagerefSnell law). But no one knew why it worked.

That is, until 11657 (holocene calendar). So another great mathematician enters our story at this point. This is Pierre Fermat!

By day he was a judge, but at night he would come home and hang out with his wife and kids and then do what he really loved the most, which was work on math for fun. And he mostly worked in pure math but at one point he got interested in the question of, why does light obey this principle of refraction?

And he thought maybe Hero of Alexandria was on the right track, but it's not distance that is being minimized, but rather time.

But to see if this was true for refraction would be difficult. He would have to work out every possible path light could take by varying the point where it intersects the boundary and compute the time for each, and then show that light takes the path for which the total travel time is the shortest. He doesn't know how to solve it and he worries that it is going to be overcomplicated even if he could solve it, so he will not do it...

Years go by, Fermat gets interested in it five years later and tries to solve it, and then he does solve it and he shows that Snell's Law actually pops out as the minimizing path for light, you know, under these conditions of moving from one medium with one speed of light to another with another (see section Optics page pagerefSnell law).

And Fermat said that this is «*the most extraordinary, the most unforeseen, and the happiest calculation" of his life*».

If you use that principle of least time, you can explain everything that was known about light at the time of Fermat. It's the first time that anyone showed that nature obeys an optimization principle, that nature does the best possible thing. In this case, that light takes the shortest possible time!

Upon finding this solution, Bernoulli wrote, «*In this way I have solved at one stroke two important problems, an optical and a mechanical one, and have achieved more than I demanded from others. I have shown that the two problems taken from entirely separate fields of mathematics have the same character*».

Little did Bernoulli know he was onto something much bigger. Around 40 years later, one of his students, Pierre Louis de Maupertuis, also studied the behavior of light and particles, and he noticed that there are cases where the two behave very similarly. This made him think, what if Fermat's principle of least time wasn't the most fundamental principle?

Why should Nature care about minimizing time? Maybe there is a more foundational quantity being minimized, one that doesn't only govern light, but also particles. So, in the 11740s (holocene calendar), he proposed a new quantity, which he named the "action".

Therefore, in a theory in which the forces derives from a potential V, we are naturally led to define the "classic Lagrangian" by (the reader must absolutely try to remember it!):

$$\boxed{L(q,\dot{q})=T(q,\dot{q})-V(q,\dot{q})} \tag{9.2.19}$$

where T and V are the traditional notation in the Lagrangian formalism for the kinetic energy and respectively potential energy given by (for a unit mass):

$$T=\frac{1}{2}\dot{q}^2 \qquad V=V(q) \tag{9.2.20}$$

The variational principle is then written in the conservative case (which facilitates the interpretation of the integral as an infinite sum of infinitesimal differences of the kinetic and potential energy between two instants and that must obviously be zero in a conservative system):

$$\delta S=\int_{t_A}^{t_B}\delta L\mathrm{d}t=\int_{t_A}^{t_B}\delta(T-V)\mathrm{d}t=\int_{t_A}^{t_B}(\delta T-\delta V)\mathrm{d}t=0 \tag{9.2.21}$$

Which implies that well known fact that in any conservative system any change of kinetic energy requires a contrary variation of potential energy (hence the fact that it is implicitly a negative sign):

$$\delta T=\delta V \tag{9.2.22}$$

Strictly speaking, we do not always have the equality between the variational of the integral of the Lagrangian and the integral of the Lagrangian variational. Sometimes it can happen that:

$$\left(\delta\int_{t_A}^{t_B}L\mathrm{d}t\right)\neq\left(\int_{t_A}^{t_B}\delta L\mathrm{d}t=0\right) \tag{9.2.23}$$

Indeed, while the integral on the right of inequality has a quite relatively easy interpretation since it is in physics since the infinite sum of infinitesimal differences between potential and kinetic energy in a conservative system is zero, the integral on the left is the inexact differential (see section Differential and Integral Calculus page 1469) who will be zero if the Lagrangian does not depend on the way and therefore by extension does not explicitly depend on the variable t.

Remark

For the study of General Relativity (see page 5720), we are not looking for the variation of the difference of energy to be minimal as it is the case for mechanical systems, but the variation in the length $\mathrm{d}s$ of an arc (not time dependent unlike the previous example) in any space during a trajectory of a free system. Which bring us to simply write (remember it also because it will be very important!) the action:

$$\delta S=\int \delta(\mathrm{d}S)=0 \tag{9.2.24}$$

for a unit mass and taking the natural units.

Maybe let us do that in another way for pedagogical reasons (some people will like the first approach and some others the second approach). Remember that using Mapertuis notation:

$$\delta S_0=0 \tag{9.2.25}$$

And using Euler generalisation:

$$\delta\int mv\mathrm{d}\ell=0 \tag{9.2.26}$$

But we have:

$$v=\frac{\mathrm{d}\ell}{\mathrm{d}t}\rightarrow \mathrm{d}\ell=v\mathrm{d}t \tag{9.2.27}$$

Therefore:

$$\delta\int mv^2\mathrm{d}t=0 \tag{9.2.28}$$

But wait, that's just twice the kinetic energy such that:

$$\delta\int 2T\mathrm{d}t=\delta\int (T+T)\mathrm{d}t=0 \tag{9.2.29}$$

And as Euler pointed out, the total energy must be conserved. Total energy is just kinetic plus potential:

$$E=T+V\rightarrow T=E-V \tag{9.2.30}$$

So we can rewrite as:

$$\delta\int (T+E-V)\mathrm{d}t=\delta\int (T-V)\mathrm{d}t+\delta\int E\mathrm{d}t=0 \tag{9.2.31}$$

And since energy is constant:

$$\delta\int(T-V)\mathrm{d}t+\delta(Et)=\delta\int(T-V)\mathrm{d}t+E\delta t+t\delta E=0 \tag{9.2.32}$$

But remember, as Euler found, the energy of different paths has to be the same, so the variation between them is 0 and the term $t\delta E$ drops out. So it remains:

$$\delta\int(T-V)\mathrm{d}t+E\delta t=0 \tag{9.2.33}$$

If we rearrange:

$$\delta\int(T-V)\mathrm{d}t=-E\delta t \tag{9.2.34}$$

This looks a lot like some other minimization principle, if only $E\delta t$ was equal to 0. Well, we can make this term 0 by only considering paths that have the same travel time. So if we do that, then there's no longer any variation in time and this term drops out and it remains:

$$\delta\int(T-V)\mathrm{d}t=\delta\int L\mathrm{d}t=0 \tag{9.2.35}$$

The first person to write the principle of least action like this was William Rowan Hamilton in 11834 (holocene calendar), and by doing so, he got the principle also named after him.

Hamilton's Principle is the modern way of writing the principle of least action and the way you would find it in almost every physics textbook.

In part that's because Hamilton's Principle tells you how objects move from one place to another rather than just giving you the shape of the path. Two other important differences between both principles are that the action is now an integral over time instead of space. And a consequence is that with Hamilton's Principle, you now need a start and end point, and also a start and end time.

After Euler found out about Lagrange's proof, he wrote to him the following: «*How satisfied would not Mr Maupertuis be, were he still alive, if he could see his principle of least action applied to the highest degree of dignity to which it is susceptible*». With Lagrange's proof, we now have two ways to solve any mechanics problem. You can either use forces and vectors or you can use energies and scalars.

To return to our application of the variational principle in the case of the generalized Lagrangian, we can write the following exact total differential (see section Differential and Integral Calculus page 1469) of δL and then we get the relation:

$$\delta S=\int\limits_{t_A}^{t_B}\delta L\mathrm{d}t=\int\limits_{t_A}^{t_B}\sum_{i=1}^{n}\left(\frac{\partial L}{\partial q_i}\delta q_i+\frac{\partial L}{\partial \dot{q}_i}\delta\dot{q}_i\right)\mathrm{d}t=0 \tag{9.2.36}$$

So the idea here is that if we have the path of least action, then if we were to change it a little bit by, say, adding a tiny bump here or flattening it out there to our path of least action, well, then the action basically shouldn't change because we are in this really special configuration: the path of least action. We add a little bit to the minimal path but the action is still the same!

Let us integrate by parts (see section Differential and Integral Calculus page 1532) the second term of the sum of the previous integral:

$$\int_{t_A}^{t_B} \frac{\partial L}{\partial \dot{q}_i}\delta \dot{q}_i \mathrm{d}t = \int_{t_A}^{t_B} \frac{\partial L}{\partial \dot{q}_i}\delta \frac{\mathrm{d}}{\mathrm{d}t}q_i \mathrm{d}t = \frac{\partial L}{\partial \dot{q}_i}\delta q_i \bigg|_{t_A}^{t_B} - \int_{t_A}^{t_B} \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}\delta q_i \mathrm{d}t \qquad (9.2.37)$$

The first term of the last equality is equal to zero:

$$\frac{\partial L}{\partial \dot{q}_i}\delta q_i \bigg|_{t_A}^{t_B} = \frac{\partial L}{\partial \dot{q}_i}(t_B)\delta q_i(t_B) - \frac{\partial L}{\partial \dot{q}_i}(t_A)\delta q_i(t_A) = \frac{\partial L}{\partial \dot{q}_i}(t_B)\cdot 0 - \frac{\partial L}{\partial \dot{q}_i}(t_A)\cdot 0 = 0 \qquad (9.2.38)$$

since we have already mentioned above that by construction we must have:

$$\delta q_i(t_A) = \delta q_i(t_B) = 0 \qquad (9.2.39)$$

The expression of the integral of least action can finally be written:

$$\delta S = \int_{t_A}^{t_B} \delta L \mathrm{d}t = \int_{t_A}^{t_B} \sum_{i=1}^{n} \left(\frac{\partial L}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}\right)\delta q_i \mathrm{d}t = 0 \qquad (9.2.40)$$

But as the δq_i and $\dot{q}_i$ tend to 0 in an infinite number of ways and we must have however $\delta S = 0$. This means that each term in the sum of the integral can be taken independently and has to satisfy:

$$\boxed{\forall i \in \mathbb{N}^* : \delta S = \int_{t_A}^{t_B} \delta L \mathrm{d}t = \int_{t_A}^{t_B} \left(\frac{\partial L}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}\right)\delta q_i \mathrm{d}t = 0} \qquad (9.2.41)$$

But as the functions δq_i and $\delta \dot{q}_i$ functions can always approach zero in many ways, and that this integral should be anyway equal to zero , we deduce that it is the integrands that are zero:

$$\boxed{\forall i \in \mathbb{N}^* : \delta S = \frac{\partial L}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i} = 0} \qquad (9.2.42)$$

These n equations, satisfied by the generalized Lagrangian of the system to effectively track movement, are named "Euler-Lagrange equations", or more briefly (but rarely) "Lagrange equations". These are, as we shall see, the equations of motion of the system: resolved, they give the effective evolution of the system over time:

$$\frac{\partial L}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i} = 0 \qquad (9.2.43)$$

or more explicitly we have the following second order differential equation:

$$\boxed{\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i} - \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i} = 0} \qquad (9.2.44)$$

And the reader must not forget that this in the case of a conservative system!!!!

If the system is not conservative, by the analysis of units we have:

$$\boxed{\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i}=F_i} \tag{9.2.45}$$

where F_i represents the generalized forces not arising from a potential (even if sometimes we consider a force arising from a potential as not arising from a potential as it is more easy to manipulate for students as it brings anyway to the same result when the force depends explicitly on the acceleration).

The Lagrange equations should describe a particle motion. Given $L=T-V$ we should expect to recover Newton's second law for a particle moving under the influence of a force. We have (see section Classical Mechanics page 3297):

$$T=\frac{1}{2}m(\dot{x}^2+\dot{y}^2+\dot{z}^2) \tag{9.2.46}$$

It follows that in absence of a potential:

$$L=T-V=T-0=T \tag{9.2.47}$$

Therefore:

$$\frac{\partial T}{\partial x}=\frac{\partial T}{\partial y}=\frac{\partial T}{\partial z}=0 \tag{9.2.48}$$

and:

$$\frac{\partial T}{\partial \dot{x}}=m\dot{x},\frac{\partial T}{\partial \dot{y}}=m\dot{y},\frac{\partial T}{\partial \dot{z}}=m\dot{z} \tag{9.2.49}$$

The non-conservative equation of motion is:

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}-\frac{\partial L}{\partial q_i}=F_i \tag{9.2.50}$$

where $q_1=x,q_2=y,q_3=z$. The equation of motion then becomes:

$$\frac{\mathrm{d}}{\mathrm{d}t}(m\dot{x})=F_x \tag{9.2.51}$$

and identically for y and z, meaning that as expected we recovered Newton's 2nd law!

✍**Example:**

A common model of friction is:

$$F_f=-Kv \tag{9.2.52}$$

(see the study of tribology in the section of Classical Mechanics at page 3452) where v is the speed of the body in translational motion. Consider the corresponding "Rayleigh dissipation function" (energy dissipation due to friction):

$$E_F=\frac{1}{2}Kv^2 \tag{9.2.53}$$

If we use a Cartesian coordinate system, the generalized force due to friction, in x-direction for instance is given by:

$$F_{f_x}=-Kv_x=-\frac{\partial E_f}{\partial v_x} \tag{9.2.54}$$

that we will also denote:

$$F_{f_1}=-Kv_1=-\frac{\partial E_f}{\partial v_1} \tag{9.2.55}$$

or as in Analytical Mechanics some physicists denote E_f by $\mathcal{F}$ we have also sometimes:

$$F_{f_1}=-Kv_1=-\frac{\partial \mathcal{F}}{\partial v_1} \tag{9.2.56}$$

Therefore through this example we see that we define the "generalized force" as:

$$\boxed{F_i=-\frac{\partial \mathcal{F}}{\partial \dot{q}_i}} \tag{9.2.57}$$

So, the equations of motion in the case of a non-conservative force is written:

$$\boxed{\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i}-\frac{\partial \mathcal{F}}{\partial \dot{q}_i}=0} \tag{9.2.58}$$

If instead, the friction was proportional to the acceleration for some reason (as do a gravitational force for example but this latter is in the V term as it arise from a potential), we could go one step further and define a new Lagrangian:

$$L=T-V+\mathcal{F} \tag{9.2.59}$$

and using Lagrange's equations on L would give us the correct answer.

Most of time when we use the Lagrangian formalism in quantum physics the studied system is in vacuum so the first boxed relation above applies but when the system if for example in a gravitational field then an external force F is applied and then second boxed relation has to be applied (see the study of the gyroscope nutation in the section of Classical Mechanics at page 3324 for a detailed example).

Remark

This is while studying physics (the following sections of this textbook) that we can better understand the applications of this equation (obtained almost by purely mathematical developments !!!) and it becomes afterwards possible to understand its deep meaning. At our level of discourse, it is pointless to say anything for the moment. We must do physics, and physics again and again... to understand it well (learning by doing as we say!).

So in the Lagrangian approach, we learn to reason from concepts of potential and kinetic energy instead of force concepts. The two approaches are obviously physically equivalent, but the energies are not vector quantities, they are conceptually easier to use in a wide range of situations. In quantum physics, for example, the notion of force has no meaning but energy concepts remains valid and same in General Relativity!!! This is one more reason to become familiar with their use. In addition, the force in the sense of Newton is instantaneous distance action. In relativity, such a thing is impossible. The concept of force is therefore a purely classical macroscopic creation and contrary to our intuition, its interest is limited.

Let us see a very first simple example of application of Euler-Lagrange's equation (other examples will be seen during our study of Newton's laws, of Electrodynamics, Special Relativity, General Relativity, Quantum Physics Fields, etc.):

✍**Examples:**

E1. First, let us write in a conventional mathematical form the Euler-Lagrange equation (the notation of the generalized coordinates is not the same in mathematics than in physics...):

$$\frac{\mathrm{d}}{\mathrm{d}x}\frac{\partial Z(x,y,y')}{\partial y'}-\frac{\partial Z(x,y,y')}{\partial y}=0 \tag{9.2.60}$$

And now we take a simple practical mathematical example internationally known and very important (we will reuse the developments made below four our study of the Huygens pendulum later).

The problem statement is: determine the shortest path between two points of a plane (we're guessing it's the straight line but must prove it!). In other words: to find the geodesic of a plane!

This problem consist to find the shortest parametrized curve $x(t), t\in[t_0,t_1]$that connects two points (caution with the variable t has nothing to do with the time in this example!) such that:

$$x(t_0)=x_0 \qquad x(t_1)=x_1 \tag{9.2.61}$$

Thus the infinitesimal length $\mathrm{d}L$ by applying Pythagoras is (differential curvilinear abscissa):

$$\begin{aligned}&\mathrm{d}L^2=\mathrm{d}t^2+\mathrm{d}x^2\\&\mathrm{d}L=\sqrt{\mathrm{d}t^2+\mathrm{d}x^2}=\sqrt{1+\frac{\mathrm{d}x^2}{\mathrm{d}t^2}}\mathrm{d}t=\sqrt{1+\dot{x}^2(t)}\mathrm{d}t\end{aligned} \tag{9.2.62}$$

Thus, the length L of the parametric curve is given by:

$$\boxed{\int\limits_{t_0}^{t_1}\sqrt{1+\dot{x}^2(t)}\mathrm{d}t} \tag{9.2.63}$$

It is a relation we will often meet again in physics and math !!

Thus, this problem, which the geometrical solution is very simple, is formulated as variational calculation problem as follows:

$$\min L(x,\dot{x},t)=\sqrt{1+\dot{x}^2} \tag{9.2.64}$$

Let us write the Euler-Lagrange of the solution to this problem, solution that if it exists, it has to satisfy.

Therefore we have:

$$\begin{gathered}
Z(x,y,y')=\sqrt{1+y'^2}\\
\frac{\partial Z}{\partial y}=0\\
\frac{\partial Z}{\partial y'}=\frac{y'}{\sqrt{1+y'^2}}
\end{gathered} \tag{9.2.65}$$

The Euler-Lagrange equation therefore becomes:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial Z(x,y,y')}{\partial y'}\right)-\frac{\partial Z(x,y,y')}{\partial y}=\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{\sqrt{1+y'^2}}\right)=0 \tag{9.2.66}$$

Therefore:

$$\frac{y}{\sqrt{1+y'^2}}=C \tag{9.2.67}$$

where $C\in\mathbb{R}$ is a constant of integration (see section Differential and Integral Calculus page 1512). The latter equality implies that (we add an index for the constant that will avoid us to confused it with two other constants that will appear little further below):

$$y'=\frac{\mathrm{d}y}{\mathrm{d}x}=C\sqrt{1-y'^2} \tag{9.2.68}$$

Returning to the notation used in the beginning of our problem statement:

$$x'=\frac{\mathrm{d}x}{\mathrm{d}t}=\dot{x}=C_1\sqrt{1-\dot{x}^2} \tag{9.2.69}$$

Therefore:

$$\dot{x}^2=C_1^2-C_1^2\dot{x}^2\Leftrightarrow(C_1^2+1)\dot{x}^2=C_1^2\Leftrightarrow\dot{x}=\sqrt{\frac{C_1^2}{C_1^2+1}} \tag{9.2.70}$$

Therefore:

$$\mathrm{d}x=C_2\mathrm{d}t \tag{9.2.71}$$

and by integration it comes:

$$x(t)=C_2t+C_2 \tag{9.2.72}$$

This is the indeed the of a line named therefore the "geodesic equation in cartesian coordinates". This can be seen obviously by rewriting the constants as:

$$x(t)=at+b \tag{9.2.73}$$

Identical to the famous line equation:

$$y(x)=ax+b \tag{9.2.74}$$

E2. We will now focus on an example frequently asked on Internet forums: what is the geodesic of an $\mathcal{S}^2$ sphere?

For this, and without using Tensor Calculus (!), let us recall that in spherical coordinates (see section Vector Calculus page 1849):

$$\mathrm{d}\vec{r}=\vec{e}_r\mathrm{d}r+\vec{e}_\theta r\mathrm{d}\theta+\vec{e}_\phi\sin(\theta)\mathrm{d}\phi \tag{9.2.75}$$

Without loss of generality, we may take the sphere to be of unit constant radius. Therefore the previous relations reduce to:

$$\mathrm{d}\vec{r}=\vec{e}_\theta\mathrm{d}\theta+\vec{e}_\phi\sin(\theta)\mathrm{d}\phi \tag{9.2.76}$$

The length of a path from a point A to B on the sphere is the given by:

$$\ell=\int\limits_A^B||\mathrm{d}\vec{r}||=\int\limits_A^B\sqrt{\mathrm{d}\theta^2+\sin^2(\theta)\mathrm{d}\phi^2}=\int\limits_{\theta_A}^{\theta_B}\sqrt{1+\sin^2(\theta)\phi'^2}\mathrm{d}\theta \tag{9.2.77}$$

So as before the variational problem is equivalent to put that:

$$\min L(\theta,\phi,\phi')=\sqrt{1+\sin^2(\theta)\phi'^2} \tag{9.2.78}$$

Now applying the Euler-Lagrange equation:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial Z(x,y,y')}{\partial y'}\right)-\frac{\partial Z(x,y,y')}{\partial y}=0 \tag{9.2.79}$$

in spherical coordinates:

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\partial L(\theta,\phi,\phi')}{\partial \phi'}\right)-\frac{\partial L(\theta,\phi,\phi')}{\partial \phi}=0 \tag{9.2.80}$$

Explicitly:

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\partial}{\partial\phi'}\sqrt{1+\sin^2(\theta)\phi'^2}\right)-\frac{\partial}{\partial\phi}\sqrt{1+\sin^2(\theta)\phi'^2}=0 \tag{9.2.81}$$

As:

$$\frac{\partial}{\partial\phi}\sqrt{1+\sin^2(\theta)\phi'^2}=0 \tag{9.2.82}$$

It remains:

$$\frac{\mathrm{d}}{\mathrm{d}\theta}\left(\frac{\partial}{\partial\phi'}\sqrt{1+\sin^2(\theta)\phi'^2}\right)=0 \tag{9.2.83}$$

Therefore:

$$\frac{\partial}{\partial\phi'}\sqrt{1+\sin^2(\theta)\phi'^2}=c^{te} \tag{9.2.84}$$

Hence:

$$\frac{1}{2}\frac{2\sin^2(\theta)\phi'}{\sqrt{1+\sin^2(\theta)\phi'^2}}=\frac{\sin^2(\theta)\phi'}{\sqrt{1+\sin^2(\theta)\phi'^2}}=c^{te} \tag{9.2.85}$$

Therefore after squaring and rearranging we get:

$$\sin^4(\theta)\phi'^2=(c^{te})^2(1+\sin^2(\theta)\phi'^2) \tag{9.2.86}$$

Hence:

$$\phi'^2\left(\sin^4(\theta)-(c^{te})^2\sin^2(\theta)\right)=(c^{te})^2 \tag{9.2.87}$$

Finally:

$$\phi'=\frac{c^{te}}{\sqrt{\sin^4(\theta)-(c^{te})^2\sin^2(\theta)}}=\frac{c^{te}}{\sin(\theta)\sqrt{\sin^2(\theta)-(c^{te})^2}} \tag{9.2.88}$$

and the problem reduces to integrating this with respect to θ as $\phi'=\mathrm{d}\phi/\mathrm{d}\theta$:

$$\phi=\int\frac{c^{te}}{\sin(\theta)\sqrt{\sin^2(\theta)-(c^{te})^2}}\mathrm{d}\theta \tag{9.2.89}$$

We substitute (see section Differential and Integral Calculus page 1475):

$$u=\frac{\cos(\theta)}{\sin(\theta)}=\frac{1}{\tan(\theta)}\overset{\text{def}}{=}\cot(\theta)\Rightarrow \mathrm{d}u=-\frac{1}{\sin^2(\theta)}\mathrm{d}\theta\overset{\text{def}}{=}-\text{cosec}^2(\theta)\mathrm{d}\theta \tag{9.2.90}$$

Then:

$$\begin{aligned}\phi&=\int\frac{c^{te}}{\sin(\theta)\sqrt{\sin^2(\theta)-(c^{te})^2}}\mathrm{d}\theta=-\int\frac{c^{te}}{\text{cosec}^2(\theta)\sin(\theta)\sqrt{\sin^2(\theta)-(c^{te})^2}}\\&=-\int\frac{c^{te}}{\sqrt{1-(c^{te})^2\text{cosec}^2(\theta)}}\mathrm{d}u\end{aligned} \tag{9.2.91}$$

But as:

$$\cos^2(\theta)+\sin^2(\theta)=1\Leftrightarrow\frac{\cos^2(\theta)}{\sin^2(\theta)}+1=\frac{1}{\sin^2(\theta)}\Leftrightarrow u^2+1=\text{cosec}^2(\theta) \tag{9.2.92}$$

Therefore:

$$\phi=-\int\frac{c^{te}}{\sqrt{1-(c^{te})^2(1+u^2)}}\mathrm{d}u \tag{9.2.93}$$

Now we substitute:

$$a=\frac{\sqrt{1-(c^{te})^2}}{c^{te}} \tag{9.2.94}$$

Hence (see section Differential and Integral Calculus page 1534):

$$\phi=-\int\frac{1}{\sqrt{a^2-u^2}}\mathrm{d}u=-\arcsin\left(\frac{u}{a}\right)+C^{te} \tag{9.2.95}$$

where C^{te} is a constant of integration that we will denote by ϕ_0. Therefore:

$$\phi-\phi_0=-\arcsin\left(\frac{u}{a}\right)\Rightarrow\sin(\phi-\phi_0)=-\frac{u}{a}\Rightarrow a\sin(\phi-\phi_0)=-u \tag{9.2.96}$$

Since, for recall, $u=\cot(\theta)$, we have finally:

$$a\sin(\phi-\phi_0)=-\cot(\theta) \tag{9.2.97}$$

Let us choose $\phi_0=\pi/2$. Then:

$$-a\cos(\phi)=-\cot(\theta) \tag{9.2.98}$$

Therefore:

$$\boxed{a\cos(\phi)=\cot(\theta)} \tag{9.2.99}$$

So this is the "parametric equation of a geodesic on a 2-sphere" and we see that this is identical to relation of the "great circle" that we get in the section of Analytical Geometry during our study of the parametrization of a sphere in a three dimensional space.

It seems to be personal preference, and all academic, whether you use the Lagrangian method $L=T-V$ or the $F=ma$ method. The two methods produce the same equations. However, in problems involving more than one variable (see typically the study of oscillating motions in the section of Classical Mechanics), it usually turns out to be much easier to write down T and V, as opposed to writing down all the forces. This is because T and V are nice and simple scalars. The forces, on the other hand, are vectors, and it is easy to get confused if they point in various directions. The Lagrangian method has the advantage that once you've written down $L=T-V$, you don't have to think anymore. All you have to do is blindly take some derivatives.

Therefore:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{x}}\right)=\frac{\partial L}{\partial x}\Rightarrow m\ddot{x}=m(l+x)\dot{\theta}^2+mg\cos(\theta)-kx \tag{9.2.100}$$

and:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{\theta}}\right)\Rightarrow\frac{\partial L}{\partial\theta}&\Rightarrow\frac{\mathrm{d}}{\mathrm{d}t}(m(l+x)^2\dot{\theta})=-mg(l+x)\sin(\theta)\\&\Rightarrow m(l+x)^2\ddot{\theta}+2m(l+x)\dot{x}\dot{\theta}=-mg(l+x)\sin(\theta)\\&\Rightarrow m(l+x)\ddot{\theta}+2m\dot{x}\dot{\theta}=-mg\sin(\theta)\end{aligned} \tag{9.2.101}$$

9.2.1.3.1 Beltrami Identity

We will prove here a useful relation named "Beltrami identity" which simplifies the application of the Euler-Lagrange equation in some particular situations!

Let us first recall the Euler-Lagrange equation:

$$\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i} \tag{9.2.102}$$

Let us write the exact total differential (see section Differential and Integral Calculus page 1466):

$$\mathrm{d}L=\frac{\partial L}{\partial t}\mathrm{d}t+\frac{\partial L}{\partial q_i}\mathrm{d}q_i+\frac{\partial L}{\partial \dot{q}_i}\mathrm{d}\dot{q}_i \tag{9.2.103}$$

What we will write under the form:

$$\frac{\mathrm{d}L}{\mathrm{d}t}=\frac{\partial L}{\partial t}+\frac{\partial L}{\partial q_i}\frac{\mathrm{d}q_i}{\mathrm{d}t}+\frac{\partial L}{\partial \dot{q}_i}\frac{\mathrm{d}\dot{q}_i}{\mathrm{d}t}=\frac{\partial L}{\partial t}+\frac{\partial L}{\partial q_i}\dot{q}_i+\frac{\partial L}{\partial \dot{q}_i}\ddot{q}_i \tag{9.2.104}$$

Rearranging:

$$\frac{\partial L}{\partial q_i}\dot{q}_i=\frac{\mathrm{d}L}{\mathrm{d}t}-\frac{\partial L}{\partial \dot{q}_i}\ddot{q}_i-\frac{\partial L}{\partial t} \tag{9.2.105}$$

Let us multiply before continuing the Euler-Lagrange by $\dot{q}_i$:

$$\dot{q}_i\frac{\partial L}{\partial q_i}-\dot{q}_i\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}=0 \tag{9.2.106}$$

and let us inject the prior previous relation in the previous one:

$$\dot{q}_i\frac{\partial L}{\partial q_i}-\dot{q}_i\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}=\left(\frac{\mathrm{d}L}{\mathrm{d}t}-\frac{\partial L}{\partial \dot{q}_i}\ddot{q}_i-\frac{\partial L}{\partial t}\right)-\dot{q}_i\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}=0 \tag{9.2.107}$$

After a small factorization we get:

$$-\frac{\partial L}{\partial t}+\frac{\mathrm{d}}{\mathrm{d}t}\left(L-\dot{q}_i\frac{\partial L}{\partial \dot{q}_i}\right)=0 \tag{9.2.108}$$

In the particular conditions (but relatively frequent in physics), which we will name in this textbook the "Beltrami condition", where:

$$\frac{\partial L}{\partial t}=0 \tag{9.2.109}$$

We get the "Beltrami identity":

$$\boxed{\frac{\mathrm{d}}{\mathrm{d}t}\left(L-\dot{q}_i\frac{\partial L}{\partial \dot{q}_i}\right)=0} \tag{9.2.110}$$

which bring us to have:

$$L-\dot{q}_i\frac{\partial L}{\partial \dot{q}_i}=c^{te} \tag{9.2.111}$$

that we will be very useful for example in the section of Classical Mechanics for our study of the brachistochrone page 3433.

9.2.1.3.2 Theorem of Variational Calculus

The theorem of variational calculus consist to prove that by considering a continuous function f on the interval $[a,b]$ on $\mathbb{R}$ and H the set of continuous functions on $[a,b]$ infinitely differentiable on $]a,b[$ and which vanish on a and b, then for any function $h\in H$:

$$\int\limits_a^b f(x)h(x)\mathrm{d}x=0 \qquad (9.2.112)$$

f is zero on $[a,b]$.

Why focus on this theorem? Because we will meet it frequently during the application of the variational principle in similar configuration. Indeed, let us recall that the variational principle leads to have:

$$\delta S=\int\delta(\mathrm{d}s)=0 \qquad (9.2.113)$$

and the integrated expression is rarely a simple function as the reader will notice in reading the different following chapters of this textbook. It is therefore important to know a property that sometimes simplifies the analysis of the problem.

Remark

Some people may think that the case $f(x)=1$ with $h(x)=\sin(x)$ and $x\in[0,2\pi]$ contradicts the statement of the theorem! In fact it's not really that ... this theorem must be valid for $\forall h\in H$ and not only just for the mentioned example. Hence the fact that f will have to be equal zero as we will prove it just now.

Proof 9.1.2. To simplify we will take the case $a=-1,b=1$. With a little bit more technical details the proof by contradiction below can be adapted to the case of any a, b.

Let us suppose that f is not on $[-1,1]$. Then there exists $x_0\in]-1,1[$ such that $f(x_0)\neq 0$. We can the suppose $f(x_0)>0$ (same reasoning if $f(x_0)<0$).

By the initial assumption of continuity and of not nullity of f there exists a small interval around x_0 on which f is strictly positive. That is to say, there exists $\varepsilon>0$ such that $[x_0-\varepsilon,x_0+\varepsilon]\subset[-1,1]$ and $\forall y\in[x_0-\varepsilon,x_0+\varepsilon], f(y)>0$.

Let us consider now the function $\pi:[-1,1]\mapsto\mathbb{R}$:

$$\phi(x)=\begin{cases} e^{-\frac{1}{1-x^2}} & \text{if } |x|<1\\ 0 & \text{otherwise}\end{cases} \qquad (9.2.114)$$

We check easily that ϕ is continuous (positive) on $[-1,1]$ and infinitely differentiable on $[-1,1[$ (see section Differential and Integral Calculus page 1496).

In addition, $\phi(-1)=\phi(1)=0$. And therefore, $\phi\in H$. Here is a graphical representation of ϕ:

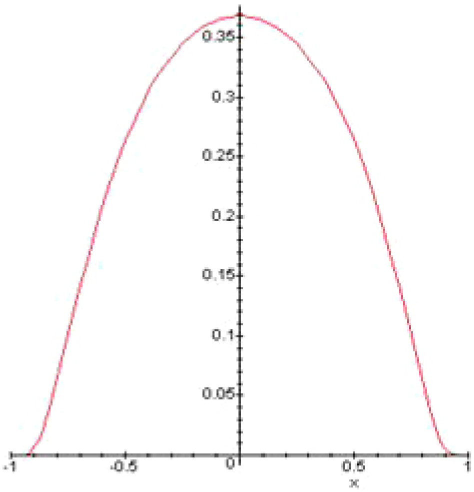

Figure 9.12: **Sample Function to prove the variational calculus**

From ϕ we want get a continuous function on $[-1,1]$, infinitely differentiable on $]-1,1[$, positive on $[x_0-\varepsilon, x_0+\varepsilon]$ and zero outside $[x_0-\varepsilon, x_0+\varepsilon]$ to show the absurdity of the assumption of non nullity of f so that the theorem is verified (remember that we are doing a proof by contradiction!).

For this, it is enough to center ϕ on x_0 and contract it.

The function $h:[-1,1]\mapsto\mathbb{R}$ defined by:

$$h(x)=\begin{cases}\phi\left(\dfrac{x-x_0}{\varepsilon}\right) & \text{if } x\in[x_0-\varepsilon,x_0+\varepsilon]\\ 0 & \text{otherwise}\end{cases} \tag{9.2.115}$$

satisfies the required criteria. Moreover, $h(-1)=h(1)=0$ and therefore $h\in H$.

Therefore, the function $f\cdot h$ will be continuous on $[-1,1]$ and positive on $[x_0-\varepsilon,x_0+\varepsilon]$ and zero everywhere else.

We have:

$$\int_{-1}^{1} f(x)h(x)\mathrm{d}x=0 \tag{9.2.116}$$

But, if a function $g:[a,b]\mapsto\mathbb{R}$ is continuous and positive and:

$$\int_{a}^{b} g(x)\mathrm{d}x=0 \tag{9.2.117}$$

this leads inevitably (we would suppose that as too intuitive to be proved) to $g=0$ on $[a,b]$.

Therefore $f(x)h(x)=0$ on $[x_0-\varepsilon,x_0+\varepsilon]$ or $f(x_0)h(x_0)\neq 0$ according to our initial absurd assumption, which is contradictory.

The starting assumption is therefore false and f must be zero on $[-1,1]$.

■ Q.E.D.

9.2.2 Canonical Formalism

The canonical formalism does not introduce a new type of physics but offers a new range of tools to study physical phenomena. Its masterpiece, the "Hamiltonian", plays an important role in quantum physics.

As in the Lagrange formalism we work with quantities (scalars) such as energy, T and V rather than with vector quantities such as the Newton force.

In the formalism of Lagrange, the description of an n degrees of freedom mechanical system is as we know described by the general (unconstrained) independent coordinates q_i that leads to n Euler-Lagrange equations of the type:

$$\frac{\partial L}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}=0 \Leftrightarrow \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{q}_i}-\frac{\partial L}{\partial q_i}=0 \tag{9.2.118}$$

which are second order differential equations (see section Differential and Integral Calculus page 1610).

With Lagrange we compare mainly trajectories and therefore the q_i and the $\dot{q}_i$ are independent. By Hamilton we must first learn to define the "general momentum" denoted $\vec{p}_i$, replacing the generalized coordinates $\dot{q}_i$ and q_i which are also independent.

Remark

The origin of the conjugated momentum will be trivial when we will see further below a first concrete example.

9.2.2.1 Legendre Transform

The "Legendre transformation" is often used in thermodynamics (see section of the same name page 3677) because it allows to interconnect the various thermodynamic potentials. In mechanics or in geometry it gives the possibility to define the Hamiltonian from the Lagrangian and vice versa. We will give here a simplified and sufficient description of it in the univariate case (that is to say: in one dimension).

Given a function $f(u,v)$ where u,v are the both independent variables of which f depends.

Let us define:

$$w:=\frac{\partial f(u,v)}{\partial}=w(u,v) \tag{9.2.119}$$

The Legendre transformation gives the possibility to define a function $g(u,w)$ that can replace $f(u,v)$ in the sense that it rid of one of the explanatory variables (which is very useful in thermodynamics!):

$$f(u,v)\mapsto g(u,w)=vw-f \tag{9.2.120}$$

Given now the total differential of f (see section Differential and Integral Calculus page 1466):

$$\mathrm{d}f=\frac{\partial f}{\partial u}\mathrm{d}u+\frac{\partial f}{\partial v}\mathrm{d}v=\frac{\partial f}{\partial u}\mathrm{u}+w\mathrm{d}v \tag{9.2.121}$$

From the definition of g we get:

$$\begin{aligned}\mathrm{d}g&=w\mathrm{d}v+v\mathrm{d}w-\mathrm{d}f\\&=w\mathrm{d}v+v\mathrm{d}w-\frac{\partial f}{\partial u}\mathrm{d}u-w\mathrm{d}v\\&=v\mathrm{d}w-\frac{\partial f}{\partial u}\mathrm{d}u=\frac{\partial g}{\partial w}\mathrm{d}w+\frac{\partial g}{\partial u}\mathrm{d}u\end{aligned} \tag{9.2.122}$$

and then we have:

$$v=\frac{\partial g}{\partial w}\qquad\frac{\partial g}{\partial u}=-\frac{\partial f}{\partial u} \tag{9.2.123}$$

Obviously we end up just with a sign difference to the same result if we put since the beginning:

$$f(u,v)\mapsto g(u,w)=f-vw \tag{9.2.124}$$

As this is usage in Thermodynamics.

9.2.2.2 Hamiltonian

Given a $L(q_i,\dot{q}_i)$ that we will assimilate the function f introduce just above with the q_i serving playing the role of the u and the $\dot{q}_i$ the role of the v. For w, we define the generalized moments also named "canonical moments".

Then for each generalized velocity, there is one corresponding conjugate momentum, defined as:

$$\boxed{p_i:=\frac{\partial L}{\partial\dot{q}_i}=p_i(q_j,\dot{q}_j)} \tag{9.2.125}$$

with $i,j\in\mathbb{N}^*$.

In Cartesian coordinates, the generalized momenta are precisely the physical linear momenta. In circular polar coordinates, the generalized momentum corresponding to the angular velocity is the physical angular momentum. For an arbitrary choice of generalized coordinates, it may not be possible to obtain an intuitive interpretation of the conjugate momenta.

Before continuing let's see what allows us to do this definition:

So we define, in analogy with g, a function of the q_i and the p_i which we will denote by $H(q_i,p_i)$:

$$\begin{array}{ccccc} g(u,w) & = & vw & - & f \\ \Downarrow & & \Downarrow & & \Downarrow \\ H(q_i,p_i) & = & \displaystyle\sum_{i=1}^{n}\dot{q}_i p_i & - & L(q_i,\dot{q}_i) \end{array}$$

The relation obtained just above (that shows clearly that the Hamiltonian is the Legendre transform of the Lagrangian!):

$$\boxed{H(q_i,p_i)=\sum_{i=1}^{n}\dot{q}_i p_i - L(q_i,\dot{q}_i)} \tag{9.2.126}$$

named "Hamilton function" or "Hamiltonian" is more than important (like everything else anyway). We will see this relation again, among others, in the section of Relativistic Quantum Physics or Quantum Field Physics. Moreover, a beautiful example of what we have seen now is given in the section of Special Relativity where we calculate the Lagrangian and Hamiltonian of a free particle. The results are quite relevant and useful and their accuracy in electrodynamics are more than amazing!

If we rewrite the relation above for one degree of freedom, we have obviously:

$$H(q_i,p_i)=\dot{q}p-L(q,\dot{q})=\dot{q}\frac{\partial L}{\partial \dot{q}}-L \tag{9.2.127}$$

Now consider the special case where:

$$H(q_i,p_i)=\dot{q}\frac{\partial L}{\partial \dot{q}}-L=0 \tag{9.2.128}$$

This means obviously that:

$$\dot{q}\frac{\partial L}{\partial \dot{q}}=L \tag{9.2.129}$$

We recognize here a special case of Euler's homogeneous function theorem (see section Functional Analysis page 2282). So $H=0$ for every Lagrangian that is homogeneous of degree 1 (i.e. re-parametrization invariant).

✍**Example:**

Another important and well known application analytical mechanics is the calculation of minimal surfaces (for physics and architecture). If we focus on the determination of such a surface by requiring it to be a surface of revolution, we will see that we find a catenoid (the form taken by a soap film between two rings).

We give us ourselves the radius R_1 and R_2 of two circles of distance between them of l. We seek a function y of class $\mathcal{C}^1$ such that:

$$y(0)=R_1 \qquad \text{and} \qquad y(l)=R_2 \tag{9.2.130}$$

and that the parametric surface of revolution of the type:

$$\{(x,y(x)\cos(\phi),y(x)\sin(\phi)),x\in[0,l],\phi[0,2\pi]\} \tag{9.2.131}$$

has a minimal surface.

We know that the surface of a volume of revolution can be written (see section Geometric Shapes page 2956):

$$S=\int 2\pi f(x)\sqrt{1+f'(x)^2}\mathrm{d}x=2\pi\int y\sqrt{1+y'^2}\mathrm{d}x=2\pi\int L(y,y')\mathrm{d}x \tag{9.2.132}$$

Thus by making the function vary:

$$\delta S=\int \delta L(y,y')\mathrm{d}x=\int\left(\frac{\partial L}{\partial y}\delta y+\frac{\partial L}{\partial y'}\delta y'\right)\mathrm{d}x \tag{9.2.133}$$

As $\delta(y')=(\delta y)'$ the integration by parts of the second term gives:

$$\int\frac{\partial L}{\partial y'}\delta y'\mathrm{d}x=\frac{\partial L}{\partial y'}\delta y-\int\left(\frac{\partial L}{\partial y'}\right)'\delta y\mathrm{d}x \tag{9.2.134}$$

As the limits of integration are fixed, the first term is zero. It then remains:

$$\int\frac{\partial L}{\partial y'}\delta y'\mathrm{d}x=-\int\left(\frac{\partial L}{\partial y'}\right)'\delta y\mathrm{d}x \tag{9.2.135}$$

and therefore:

$$\delta S=\int \delta L(y,y')\mathrm{d}x=\int\left(\frac{\partial L}{\partial y}\delta y'-\left(\frac{\partial L}{\partial y'}\right)'\delta y\right)\mathrm{d}x=\int\left(\frac{\partial L}{\partial y}-\left(\frac{\partial L}{\partial y'}\right)'\right)\delta y\mathrm{d}x \tag{9.2.136}$$

The minimum we sought corresponds to $\delta S=0$ whatever δy, which imposes the condition:

$$\left(\frac{\partial L}{\partial y'}\right)'-\frac{\partial L}{\partial y}=0 \tag{9.2.137}$$

we fall back on the Euler-Lagrange equation.

This equation can also be written in another form. By introducing the canonical momentum to simplify:

$$p=\frac{\partial L}{\partial y'} \tag{9.2.138}$$

Then we get immediately:

$$\left(\frac{\partial L}{\partial y'}\right)'-\frac{\partial L}{\partial y}=0\Rightarrow p'-\frac{\partial L}{\partial y}=0\Rightarrow p'=\frac{\partial L}{\partial y} \tag{9.2.139}$$

We then get:

$$\mathrm{d}L=\frac{\partial L}{\partial y}\mathrm{d}y+\frac{\partial L}{\partial y'}\mathrm{d}y'=p'\mathrm{d}y+p\mathrm{d}y' \tag{9.2.140}$$

Thus, putting the analogy seen earlier above (Hamilton's method):

$$H(y,p)=py'-L \tag{9.2.141}$$

We arrive at:

$$\mathrm{d}H=\mathrm{d}(y'p-L)=\mathrm{d}\left(y'\frac{\partial L}{\partial y'}-L\right)=0 \tag{9.2.142}$$

Therefore, remembering that at the beginning we had:

$$S=2\pi\int\sqrt{1+y'^2}\mathrm{d}x=2\pi\int L(y,y')\mathrm{d}x \tag{9.2.143}$$

we arrive at:

$$y'\frac{\partial L}{\partial y'}-L=\frac{yy'^2}{\sqrt{1+y''2}}-y\sqrt{1+y'^2}=\frac{-y}{\sqrt{1+y'^2}}=c^{te} \tag{9.2.144}$$

What we can also note (because the constant has an undetermined sign):

$$\frac{-y}{\sqrt{1+y'^2}}=-c^{te} \tag{9.2.145}$$

Then we have:

$$\frac{y}{\sqrt{1+y'^2}}=c^{te} \tag{9.2.146}$$

We have already integrated this type of differential equation in detail in the section of Civil Engineering during the study of the chain shape (see page 8558). The result is:

$$y=\frac{1}{c^{te}}\cosh\left(\frac{x}{c^te}+c_1^{te}\right)+c_2^{te} \tag{9.2.147}$$

the surface of revolution of this curve being a catenoid:

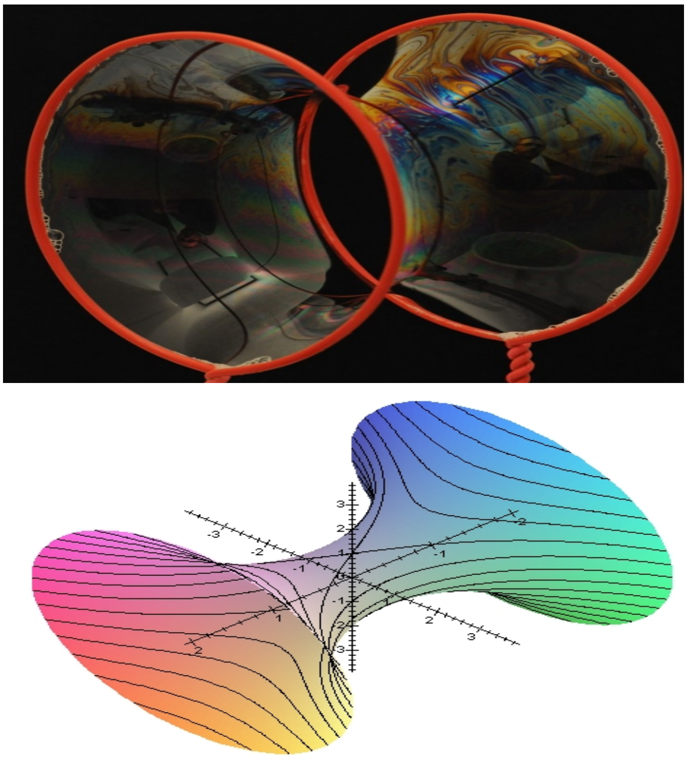

Figure 9.13: **Catenoid made of soap between two circular rings and with Maple™ 4.00b**

This figure can be obtained with Maple™ 4.00b as follows:

```
>y:=cosh(x);
>y:=cosh(x);plot3d([x,y*cos(phi),y*sin(phi)],x=-2..2,phi=-2*Pi..2*Pi,
numpoints = 50000,axes=normal,contours=10,style=patchcontour);
```

Now if L depends on the time (which is still often the case ...) we have as total differential:

$$\mathrm{d}L=\sum_{i=1}^{n}\frac{\partial L}{\partial q_i}\mathrm{d}q_i+\sum_{i=1}^{n}\frac{\partial L}{\partial \dot{q}_i}\mathrm{d}\dot{q}_i+\frac{\partial L}{\partial t}\mathrm{d}t=\sum_{i=1}^{n}\frac{\partial L}{\partial q_i}\mathrm{d}q_i+\sum_{i=1}^{n}p_i\mathrm{d}\dot{q}_i+\frac{\partial L}{\partial t}\mathrm{d}t \qquad (9.2.148)$$

we also calculate the total differential of $H(q_i,p_i)$ and substitute in it results previously obtained:

$$\mathrm{d}H=\sum_{i=1}^{n}q_i\mathrm{d}p_i+\sum_{i=1}^{n}p_i\mathrm{d}\dot{q}_i-\left[\sum_{i=1}^{n}\frac{\partial L}{\partial q_i}\mathrm{d}q_i+\sum_{i=1}^{n}p_i\mathrm{d}\dot{q}_i+\frac{\partial L}{\partial t}\mathrm{d}t\right]=\sum_{i=1}^{n}q_i\mathrm{d}p_i-\sum_{i=1}^{n}\frac{\partial L}{\partial q_i}\mathrm{d}q_i-\frac{\partial L}{\partial t}\mathrm{d}t \qquad (9.2.149)$$

which shows well that $H(q_i,p_i)$ is function of the q_i and of the time t.

We can also write for its total differential:

$$\mathrm{d}H=\sum_{i=1}^{n}\frac{\partial H}{\partial p_i}\mathrm{d}p_i+\sum_{i=1}^{n}\frac{\partial H}{\partial q_i}\mathrm{d}q_i+\frac{\partial H}{\partial t}\mathrm{d}t \qquad (9.2.150)$$

and as the q_i and p_i are independent we identify, by comparing the two expressions, that:

$$\boxed{\begin{aligned}\frac{\partial H}{\partial q_i}&=-\frac{\partial L}{\partial q_i}\\ \frac{\partial H}{\partial p_i}&=\dot{q}_i\\ \frac{\partial H}{\partial t}&=-\frac{\partial L}{\partial t}\end{aligned}} \tag{9.2.151}$$

These relations are extremely important because we will see and use them again in the section of Magnetostatics in Relativistic Quantum Physics and Quantum Field Theory in a somewhat more barbaric form (but beautiful too...).

The prior previous relation can be written obviously:

$$\frac{\mathrm{d}H}{\mathrm{d}t}=\sum_{i=1}^{n}\left[\frac{\partial H}{\partial p_i}\frac{\mathrm{d}p_i}{\mathrm{d}t}+\frac{\partial H}{\partial q_i}\frac{\mathrm{d}q_i}{\mathrm{d}t}\right]+\frac{\partial H}{\partial t} \tag{9.2.152}$$

Let us now consider the second term of the first member of the Euler-Lagrange equation. We have:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial}{\partial \dot{q}_i}\right)=\frac{\mathrm{d}}{\mathrm{d}t}(p_i)=\frac{\partial L}{\partial q_i}=\dot{p}_i \tag{9.2.153}$$

and therefore we get the $2n$ equations below (the first line describes velocity as a function of how energy changes with momentum, and the second line describes how force varies with the negative of the energy gradient with respect to position):

$$\left.\begin{aligned}\dot{q}_i&=\frac{\partial H}{\partial p_i} \qquad \text{i=1,2,}\ldots\text{,n}\\ \dot{p}_i&=-\frac{\partial H}{\partial q_i} \qquad \text{i=1,2,}\ldots\text{,n}\end{aligned}\right\}2n$$

These $2n$ equations are named "canonical equations of motion" and are differential equations of the first order.

So now we can write the prior previous relation after rearrangement as:

$$\boxed{\frac{\mathrm{d}H}{\mathrm{d}t}=\sum_{i=1}^{n}\left[-\frac{\partial H}{\partial q_i}\frac{\partial H}{\partial p_i}-\frac{\partial H}{\partial p_i}\right]+\frac{\partial H}{\partial t}} \tag{9.2.154}$$

Remark

The appearance of the minus sign "$-$" between the equations for the q_i and those for their conjugate moments, is named a "symplectic symmetry".

From:

$$\mathrm{d}H=\sum_{i=1}^{n}\frac{\partial H}{\partial p_i}\mathrm{d}p_i+\sum_{i=1}^{n}\frac{\partial H}{\partial q_i}\mathrm{d}q_i+\frac{\partial H}{\partial t}\mathrm{d}t \tag{9.2.155}$$

we can, on a trajectory that obeys the canonical equations, compute:

$$\frac{\mathrm{d}H}{\mathrm{d}t}=\sum_{i=1}^{n}\frac{\partial H}{\partial p_i}\mathrm{d}\dot{p}_i+\sum_{i=1}^{n}\frac{\partial H}{\partial q_i}\mathrm{d}\dot{q}_i+\frac{\partial H}{\partial t}\quad=-\sum_{i=1}^{n}\dot{p}_i\dot{q}_i+\sum_{i=1}^{n}\dot{q}_i\dot{p}_i+\frac{\partial H}{\partial t}=\frac{\partial H}{\partial t}=-\frac{\partial L}{\partial t} \tag{9.2.156}$$

If H does not depend on time then we have $\partial H/\partial t=0$, i.e.:

$$\frac{\partial}{\partial t}\left(\sum_{i=1}^{n}\dot{q}_i\frac{\partial L}{\partial \dot{q}_i}-L(q_i,\dot{q}_i)\right)=0 \tag{9.2.157}$$

then H (and L) are a "constant of movement", i.e.:

$$\sum_{i=1}^{n}\dot{q}_i\frac{\partial L}{\partial \dot{q}_i}-L(q_i,\dot{q}_i)=c^{te} \tag{9.2.158}$$

What must be understood so far is that in Newtonian mechanics, the time evolution is obtained by computing the total force being exerted on each particle of the system, and from Newton's second law, the time-evolutions of both position and velocity are computed. In contrast, in Hamiltonian mechanics, the time evolution is obtained by computing the Hamiltonian of the system in the generalized coordinates and inserting it in the Hamiltonian equations. This approach is equivalent to the one used in Lagrangian mechanics. In fact, the Hamiltonian is as we just seen the Legendre transform of the Lagrangian when holding q and t fixed and denoting p as the dual variable, and thus both approaches give the same equations for the same generalized momentum. The main motivation to use Hamiltonian mechanics instead of Lagrangian mechanics comes from the symplectic structure of Hamiltonian systems.

An example seems indispensable to us at this level of advancement of the study of the Lagrangian formalism. We will restrict ourselves to a particular case of a particle subjected to a force in one dimension. But even if this example and the related developments are simple we will find the results here in many other following sections of this textbook. It is therefore important for the reader to study and understand well what will follow (which unfortunately also requires that the contents of the section of Classical Mechanics is known by the reader).

✍**Example:**

Given a particle of mass m travelling in one dimension (say x) and subjected to a force derived from a potential such that:

$$F_x=-\frac{\partial V}{\partial x}\Leftrightarrow \ddot{x}=-\frac{1}{m}\frac{\partial V}{\partial x}=-(\vec{\nabla}V)_x \tag{9.2.159}$$

We know that its Lagrangian is:

$$L=\frac{1}{2}m\dot{x}^2-V(x) \tag{9.2.160}$$

We will have only one momentum (the linear momentum), denoted p as always, conjugated to x and defined as we also know by:

$$p=\frac{\partial L}{\partial \dot{x}} \tag{9.2.161}$$

equation that we can (that we must!) reverse (from the definition of the linear momentum):

$$\dot{x}=\frac{p}{m} \tag{9.2.162}$$

We may notice at this point that the momentum p corresponds (hazard...!!) to the component x of the elementary definition $p=mv$ (which is not always the case trivially).

As defined by the Hamiltonian then it comes:

$$H=\dot{x}(p)p-L(x,\dot{x}(p))=\frac{p}{m}p-\frac{m}{2}\left(\frac{p}{m}\right)^2+V(x)=\frac{p^2}{2m}+V(x) \tag{9.2.163}$$

That we often write in the form:

$$\boxed{H=T+V} \tag{9.2.164}$$

where T is therefore the kinetic energy expressed in function of the momentum.

Caution! A typical error when comparing side by side the hamiltonian and the lagrangian:

$$\begin{aligned}\mathrm{d}L&=\left(\frac{\partial L}{\partial q}\right)\mathrm{d}q+\left(\frac{\partial L}{\partial \dot{q}}\right)\mathrm{d}\dot{q}\\ \mathrm{d}H&=\left(\frac{\partial H}{\partial q}\right)\mathrm{d}q+\left(\frac{\partial H}{\partial p}\right)\mathrm{d}p\end{aligned} \tag{9.2.165}$$

is to forget that finding $\frac{\partial L}{\partial q}$ corresponds to wiggling q while holding $\dot{q}$ fixed. On the other hand, finding $\frac{\partial H}{\partial q}$ corresponds to wiggling q while holding p fixed. If p can be expressed as a function of $\dot{q}$ only (!!!), then these two situations coincide - however, if it also depends on q, then they do not, and the two partial derivatives are referring to two different things!

Explicitly, having $p=p(q,\dot{q})$. Then using the chain rule, we find that:

$$\mathrm{d}H=\left(\frac{\partial H}{\partial q}\right)\mathrm{d}q+\left(\frac{\partial H}{\partial p}\right)\left[\frac{\partial p}{\partial q}\mathrm{d}q+\frac{\partial p}{\partial \dot{q}}\mathrm{d}\dot{q}\right] \tag{9.2.166}$$

So, if we shift q but hold $\dot{q}$ fixed (as a special example), we find that:

$$\mathrm{d}L=\left(\frac{\partial L}{\partial q}\right)\mathrm{d}q \tag{9.2.167}$$

while:

$$\mathrm{d}H=\left[\left(\frac{\partial H}{\partial q}\right)+\left(\frac{\partial H}{\partial p}\right)\left(\frac{\partial p}{\partial q}\right)\right]\mathrm{d}q \tag{9.2.168}$$

If $L(q,\dot{q})=H(q,p(q,\dot{q}))$ as in the case of a free particle, then we would find that:

$$\mathrm{d}L=\mathrm{d}H \tag{9.2.169}$$

and that therefore:

$$\left(\frac{\partial L}{\partial q}\right)=\left(\frac{\partial H}{\partial q}\right)+\left(\frac{\partial H}{\partial p}\right)\left(\frac{\partial p}{\partial q}\right) \tag{9.2.170}$$

9.2.2.3 Poisson bracket

The Poisson bracket is an important binary operation in Hamiltonian mechanics, playing a central role in Hamilton's equations of motion, which govern the time evolution of a Hamiltonian dynamical system. This formalism and definition will be quite useful to us in the section of Wave Quantum Mechanics.

The Poisson bracket $\{A,B\}_{q,p}$ is the standard way of writing a certain operation that involves the quantities $A(q_i,p_i)$ and $B(q_i,p_i)$ and also all canonical variables (q_i,p_i) defined by:

$$\boxed{\{A,B\}_{q,p} := \sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right]} \tag{9.2.171}$$

that expresses the way to travel in a field (the bracket content is zero if the two paths are equal).

We recognize here (!!!) the expression in brackets we introduced earlier above:

$$\frac{\mathrm{d}H}{\mathrm{d}t}=\sum_{i=1}^{n}\left[\frac{\partial H}{\partial p_i}\frac{\mathrm{d}p_i}{\mathrm{d}t}+\frac{\partial H}{\partial q_i}\frac{\mathrm{d}q_i}{\mathrm{d}t}\right]+\frac{\partial H}{\partial t} \tag{9.2.172}$$

Where as:

$$\boxed{\frac{\mathrm{d}H}{\mathrm{d}t}=\sum_{i=1}^{n}\left[\frac{\partial H}{\partial q_i}\frac{\partial H}{\partial p_i}-\frac{\partial H}{\partial p_i}\frac{\partial H}{\partial q_i}\right]+\frac{\partial H}{\partial t}} \tag{9.2.173}$$

From the definition of $\{A,B\}_{q,p}$ we can deduce some relatively trivial properties that will be useful to us in the sections of Wave Quantum Physics and Relativistic Quantum Physics:

P1. $\{A,B\}=-\{B,A\}$

Proof 9.1.3.

$$\begin{aligned}\{A,B\}&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right]=\sum_{i=1}^{n}\left[-\frac{\partial B}{\partial q_i}\frac{\partial A}{\partial p_i}+\frac{\partial B}{\partial p_i}\frac{\partial A}{\partial q_i}\right]\\&=-\sum_{i=1}^{n}\left[\frac{\partial B}{\partial p_i}\frac{\partial A}{\partial q_i}-\frac{\partial B}{\partial q_i}\frac{\partial A}{\partial p_i}\right]\\&=-\{B,A\}\end{aligned} \tag{9.2.174}$$

■ Q.E.D.

P2. $\{A,B+C\}=\{A,B\}+\{A,C\}$

Proof 9.1.4.

$$\begin{aligned}\{A,B+C\}&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial(B+C)}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial(B+C)}{\partial q_i}\right]\\&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\left(\frac{\partial B}{\partial p_i}+\frac{\partial C}{\partial p_i}\right)-\frac{\partial A}{\partial p_i}\left(\frac{\partial B}{\partial q_i}+\frac{\partial C}{\partial q_i}\right)\right]\\&=\sum_{i=1}^{n}\left[\left(\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right)+\left(\frac{\partial A}{\partial q_i}\frac{\partial C}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial C}{\partial q_i}\right)\right]\\&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right]+\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial C}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial C}{\partial q_i}\right]\\&=\{A,B\}+\{A,C\}\end{aligned} \tag{9.2.175}$$

■ Q.E.D.

P3. $\{A,BC\}=B\{A,C\}+C\{A,B\}$

Proof 9.1.5.

$$\begin{aligned}\{A,BC\}&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial(BC)}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial(BC)}{\partial q_i}\right]\\&=\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\left(B\frac{\partial C}{\partial p_i}+C\frac{\partial B}{\partial p_i}\right)-\frac{\partial A}{\partial p_i}\left(B\frac{\partial C}{\partial q_i}+C\frac{\partial B}{\partial q_i}\right)\right]\\&=\sum_{i=1}^{n}\left[B\left(\frac{\partial A}{\partial q_i}\frac{\partial C}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial C}{\partial q_i}\right)+C\left(\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right)\right]\\&=B\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial C}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial C}{\partial q_i}\right]+C\sum_{i=1}^{n}\left[\frac{\partial A}{\partial q_i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial q_i}\right]\\&=B\{A,C\}+C\{A,B\}\end{aligned} \tag{9.2.176}$$

■ Q.E.D.

P4. $\{A,\{B,C\}\}+\{C,\{A,B\}\}+\{B,\{C,A\}\}=0$

Proof 9.1.6.

$$\begin{aligned}&\{A,\{B,C\}\}+\{C,\{A,B\}\}+\{B,\{C,A\}\}\\&=\sum_{i=1}^{n}\left[\partial_q A\partial_p\left(\sum_{i=1}^{n}[\partial_q B\partial_p C-\partial_p B\partial_q C]\right)-\partial_p A\partial_q\left(\sum_{i=1}^{n}[\partial_q B\partial_p C-\partial_p B\partial_q C]\right)\right]\\&+\sum_{i=1}^{n}\left[\partial_q C\partial_p\left(\sum_{i=1}^{n}[\partial_q A\partial_p B-\partial_p A\partial_q B]\right)-\partial_p C\partial_q\left(\sum_{i=1}^{n}[\partial_q A\partial_p B-\partial_p A\partial_q B]\right)\right]\\&+\sum_{i=1}^{n}\left[\partial_q B\partial_p\left(\sum_{i=1}^{n}[\partial_q C\partial_p A-\partial_p C\partial_q A]\right)-\partial_p B\partial_q\left(\sum_{i=1}^{n}[\partial_q C\partial_p A-\partial_p C\partial_q A]\right)\right]\end{aligned} \tag{9.2.177}$$

Well and here, just to not have an unreadable long and boring stuff we will prove the property for $n=1$ and assume (of course) that it is valid for all n:

$$\begin{aligned}
&\{A,\{B,C\}\}+\{C,\{A,B\}\}+\{B,\{C,A\}\}\\
&=\partial_q A\partial_p\left[\partial_q B\partial_p C-\partial_p B\partial_q C\right]-\partial_p A\partial_q\left[\partial_q B\partial_p C-\partial_p B\partial_q C\right]\\
&+\partial_q C\partial_p\left[\partial_q A\partial_p B-\partial_p A\partial_q B\right]-\partial_p C\partial_q\left[\partial_q A\partial_p B-\partial_p A\partial_q B\right]\\
&+\partial_q B\partial_p\left[\partial_q C\partial_p A-\partial_p C\partial_q A\right]-\partial_q B\partial_q\left[\partial_q C\partial_p A-\partial_p C\partial_q A\right]\\
&=\partial_q A\partial_{p,q}B\partial_p C+\partial_q A\partial_q B\partial_{p,p}C-\partial_q A\partial_{p,p}B\partial_q C-\partial_q A\partial_p B\partial_{p,q}C\\
&-\partial_p A\partial_{q,q}B\partial_p C-\partial_p A\partial_q B\partial_{q,p}C+\partial_p A\partial_{q,p}B\partial_q C+\partial_p A\partial_p B\partial_{q,q}C\\
&+\partial_q C\partial_{p,q}A\partial_p B+\partial_q C\partial_q A\partial_{p,p}B-\partial_q C\partial_{p,p}A\partial_q B-\partial_q C\partial_p A\partial_{p,q}B\\
&-\partial_p C\partial_{q,q}A\partial_p B-\partial_p C\partial_q A\partial_{q,p}B+\partial_p C\partial_{q,p}A\partial_q B+\partial_p C\partial_p A\partial_{q,q}B\\
&+\partial_q B\partial_{p,q}C\partial_p A+\partial_q B\partial_q C\partial_{p,p}A-\partial_q B\partial_{p,p}\partial_q A-\partial_q B\partial_p C\partial_{p,q}A\\
&-\partial_p B\partial_{q,q}C\partial_p A-\partial_p B\partial_q C\partial_{q,p}A+\partial_p B\partial_{q,p}C\partial_q A+\partial_p B\partial_p C\partial_{q,q}A
\end{aligned}\tag{9.2.178}$$

We have also (see section Differential and Integral Calculus page 1469) under certain conditions the property $\partial_{p,q}=\partial_{q,p}$. Therefore all the terms cancel (this is elementary algebra normally...) for finally have:

$$\{A,\{B,C\}\}+\{C,\{A,B\}\}+\{B,\{C,A\}\}\tag{9.2.179}$$

$$\tag{9.2.180}$$

expression named "Jacobi identity".

That is to say written in another way (perhaps more obvious) for binary operation × on a set S possessing a binary operation $+$ with an additive identity denoted by 0 satisfies the Jacobi identity if:

$$a\times(b\times c)+c\times(a\times b)+b\times(c\times a)=0\quad\forall a,b,c\in S\tag{9.2.181}$$

That is, the sum of all even permutations of $(a,(b,c))$ must be zero.

■ Q.E.D.

Now let us use the Poisson brackets with physical quantities! As by definition the coordinates and the linear momentum are not directly dependent, we have when we put $A=q_j$ and $B=q_k$:

$$\frac{\partial q_j}{\partial p_i}=0,\ \frac{\partial q_k}{\partial p_i}=0\tag{9.2.182}$$

Therefore:

$$\{q_k,q_j\}=\sum_{i=1}^{n}\left[\frac{\partial q_k}{\partial q_i}\frac{\partial q_j}{\partial p_i}-\frac{\partial q_k}{\partial p_i}\frac{\partial q_j}{\partial q_i}\right]=\sum_{i=1}^{n}\left[\frac{\partial q_k}{\partial q_i}\cdot 0-0\cdot\frac{\partial q_j}{\partial q_i}\right]=0\tag{9.2.183}$$

hence:

$$\{q_k,q_j\}=\{q_j,q_k\}=0\tag{9.2.184}$$

and identically:

$$\{p_k,p_j\}=\{p_j,p_k\}=0\tag{9.2.185}$$

But:

$$\{q_k,p_j\}=\sum_{i=1}^{n}\left[\frac{\partial q_k}{\partial q_i}\frac{\partial p_j}{\partial p_i}-\frac{\partial q_k}{\partial p_i}\frac{\partial p_j}{\partial q_i}\right]=\sum_{i=1}^{n}\frac{\partial q_k}{\partial q_i}\frac{\partial p_j}{\partial p_i}=\sum_{i=1}^{n}\delta_{ki}\delta_{ji}=\delta_{kj} \tag{9.2.186}$$

where for recall δ_{kj} is the Kronecker symbol defined par:

$$\delta_{kj}=\delta^{jk}=\begin{cases}1 & \text{if } k=j\\ 0 & \text{if } k\neq j\end{cases} \tag{9.2.187}$$

We have also:

$$\{p_j,q_k\}=\sum_{i=1}^{n}\left[\frac{\partial p_j}{\partial q_i}\frac{\partial q_k}{\partial p_i}-\frac{\partial p_j}{\partial p_i}\frac{\partial q_k}{\partial q_i}\right]=-\sum_{i=1}^{n}\frac{\partial p_j}{\partial p_i}\frac{\partial q_k}{\partial q_i}=-\sum_{i=1}^{n}\delta_{ji}\delta_{ki}=-\delta_{kj} \tag{9.2.188}$$

It comes therefore:

$$\boxed{\{q_k,p_j\}\neq\{p_j,q_k\}} \tag{9.2.189}$$

This implies a fairly general result that we see again in the section of Wave Quantum Physics:

$$\{q_k,p_j\}-\{p_j,q_k\}\neq 0 \tag{9.2.190}$$

when $k\neq j$.

9.2.2.4 Canonical transformations

We say that of the q_i,p_i that they are "generalized canonical variables". It is not an understatement as there is virtually no limit to what they can represent physically.

That being the case, there must be transformations between these different choices. We will denote by Q_i,P_i the new canonical variables obtained after such a transformation.

We are not surprised to see that these changes are subject to fairly strict conditions. Indeed, the q_i,p_i are generalized and obey as we have just prove above:

$$\{q_k,q_j\}=0 \qquad \{p_k,p_j\}=0 \qquad \{q_k,p_j\}=\delta_{kj} \tag{9.2.191}$$

and the canonical equations:

$$\dot{q}_i=\frac{\partial H}{\partial p_i} \qquad \dot{p}_i=-\frac{\partial H}{\partial q_i} \tag{9.2.192}$$

are form invariant.

Thus, after a transformation of the q_i,p_i to the Q_i,P_i and defining a new hamiltonian that we will denote by $K(Q_i,P_i)$ we should have:

$$\{Q_k,Q_j\}=0 \qquad \{P_k,P_j\}=0 \qquad \{Q_k,P_j\}=\delta_{kj} \tag{9.2.193}$$

and the canonical equations:

$$\dot{Q}_i = \frac{\partial K}{\partial p_i} \qquad \dot{P}_i = -\frac{\partial K}{\partial q_i} \tag{9.2.194}$$

Strictly speaking, the equations of transformation can be written:

$$\begin{aligned} Q_i &= Q_i(q_j, p_j, t) \\ P_i &= P_i(q_j, p_j, t) \end{aligned} \tag{9.2.195}$$

with $i, j = 1, 2, \ldots, n$ and must be able to reverse as the physics remains independent of the variables we use to describe it, so we can write the inverse transformations:

$$\begin{aligned} q_i &= q_i(Q_j, P_j, t) \\ p_i &= p_i(Q_j, P_j, t) \end{aligned} \tag{9.2.196}$$

with $i, j = 1, 2, \ldots, n$.

The q_i, p_i, Q_i, P_i form $4n$ variables but it is obvious that only $2n$ of them are independent.

9.3. Classical Mechanics

BEFORE introducing the study of moving solid bodies as part of Classical Mechanics (at the opposite of relativistic mechanics) also named "rational mechanics" or "Newtonian mechanics", it may seem in the natural order of things to define and study first the properties relative to their static state.

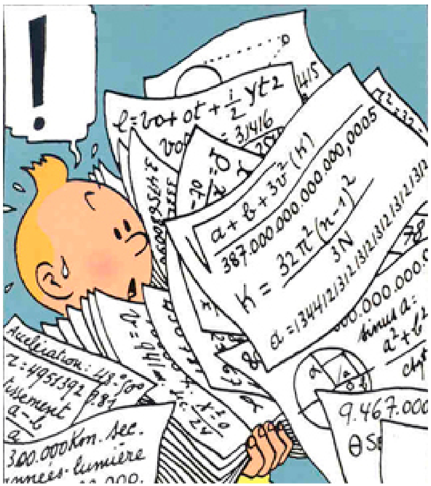

Figure 9.14: **All rights reserved ©Moulinsart**

Definitions (#9.3.424):

D1. A phenomenon is said to "static" or in "equilibrium" when it suffers of no dynamics (no acceleration or verbatim: "no unbalanced forces"), at least in appearance. We can consider an equilibrium as a static state, although even if it is apparent because it can be the result of two opposing dynamics that cancel themselves! Thus, the variables which describe a static phenomenon are constants, the concrete values of these quantities can be calculated. Static is a major case study in Mechanical engineering and Civil Engineering (see sections of the same name page 8359 and page 8539).

In a more technical way this definition is raised to the rank of principle named the "fundamental principle of static" which states that for a system to be in equilibrium, it is necessary that the general resultant and the resultant moment of the external forces is equivalent to zero relative to its center of mass or gravity (the condition is sufficient for mechanical problems that deal with non-deformable solids).

D2. The "Static" is the study of the conditions of equilibrium of a material point or body subjected to forces that are in equilibrium (cancelling themselves).

D3. Any cause that can accelerate (concept defined in detail further below) or distort a body is named a "force" (a concept introduced by Newton and rigorously to which we return in detail later in the statement of three Newton's laws).

An in-deep observation showed that a force is a macroscopic result of complex microscopic phenomena, namely interactions distance between particles. These interactions are in the number of 4 and we do not wish to talk about these 4 interactions now because they make use of mathematical tools that are out of context in this section of the book.

Remark

In Classical Mechanics we naturally do not ask ourself on the question of a transformation of time. The changes we focus on a related only to the measures "position" and its derivatives (velocity and acceleration). Indeed, in Classical Mechanics, we postulate the "Newton's time": time flows in the same way from one referential to another.

D4. If the lines of action of all the forces acting on a body are in the same plane, the system of forces named "coplanar system":

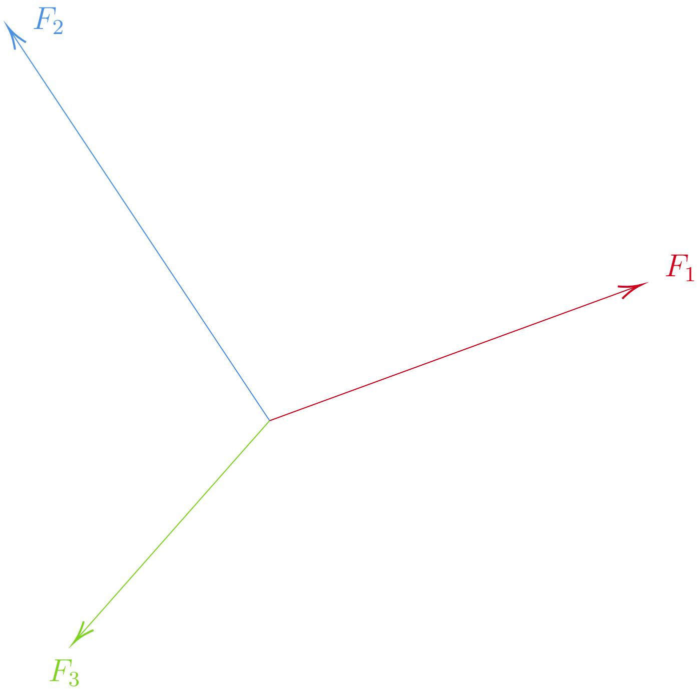

Figure 9.15: **Particular case of coplanar system**

where the intersection of forces is named a "forces node".

If we consider for example a particular set of coplanar forces whose intensities (norms) were measured using a dynamometer and angles relatively to an appropriately selected reference with a protractor. We will have a diagram of the following type named "dyname" (abbreviation of "dynamic diagram"):

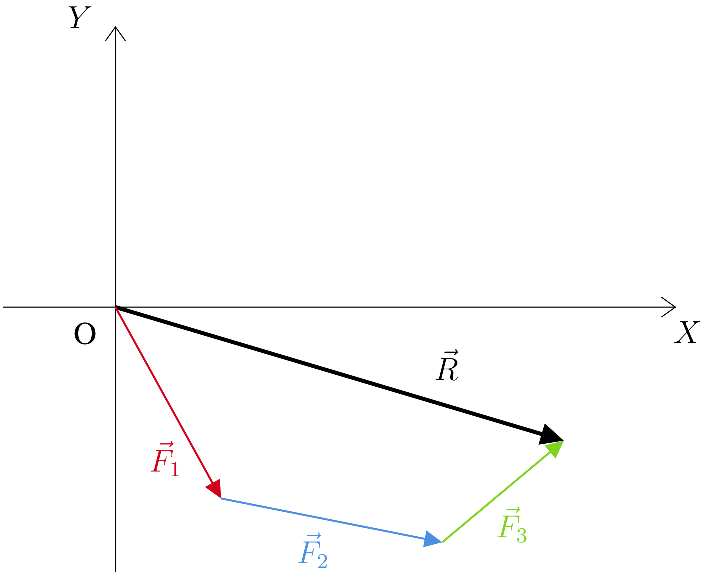

Figure 9.16: **Particular example of a measured coplanar system (dyname)**

To calculate the components of the resulting (and thus its norm), it may be easier sometimes to represent the three forces in the following form (after translation to a common point):

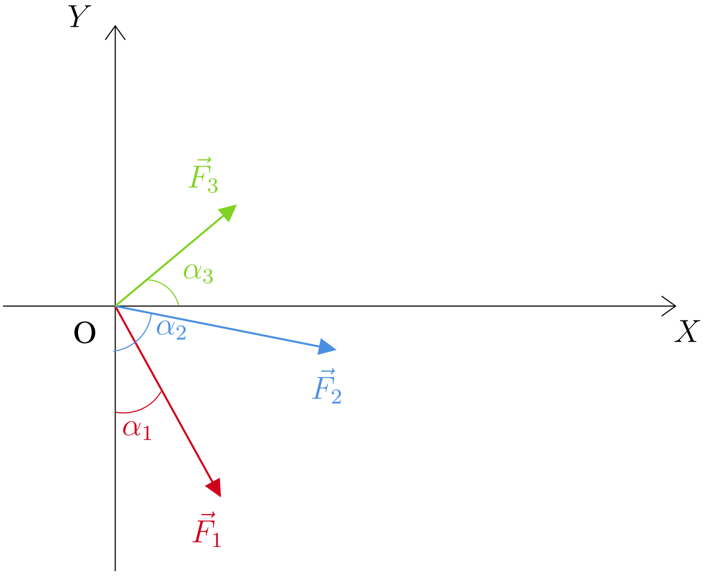

Figure 9.17: **Simplified representation of forces for treatment (translated dyname)**

Then, using elementary trigonometry, knowing the angles and the intensity of each of the three forces, it is possible to determine their respective components along the X and Y and their algebraic sum along each of the axes give the components of the resultant (today this type of reasoning sounds simple but it took still until the late 116th century (holocene calendar) that these reasonings on static forces emerges).

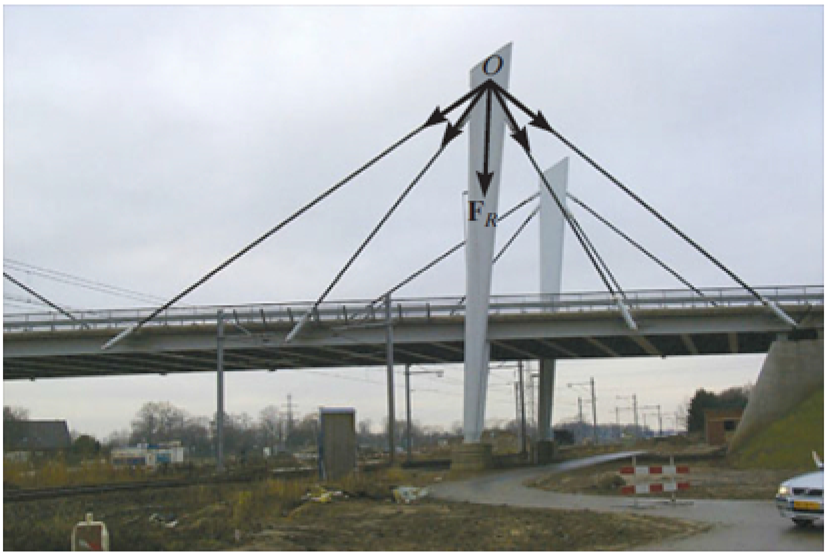

Figure 9.18: **Representation of the resultant of forces of a suspended bridge**

A small basic application case is the porting of a load:

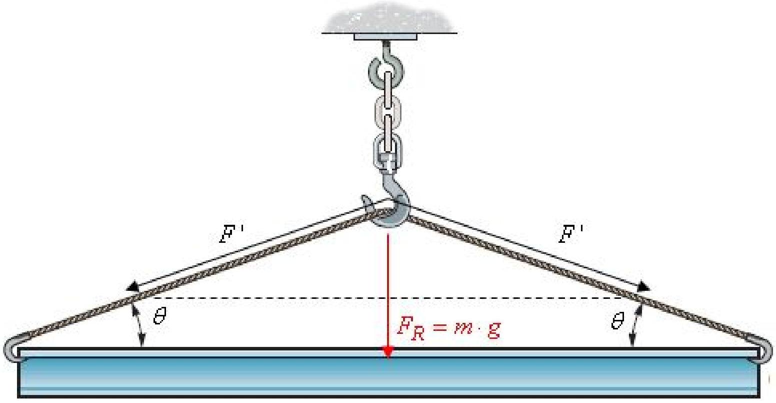

Figure 9.19: **Coplanar symmetrical load porting**

By symmetry each of the left/right part of the cable is under the same tension (force). Applying elementary trigonometry (see section Trigonometry page 2503), we have:

$$\frac{\frac{F_R}{2}}{F'} = \cos\left(\pi - \frac{\pi}{2} - \theta\right) = \cos\left(\frac{\pi}{2} - \theta\right) = \sin(\theta) \tag{9.3.1}$$

Therefore:

$$F' = \frac{\frac{F_R}{2}}{\sin(\theta)} \tag{9.3.2}$$

We notice that we have an interest in having:

$$\sin(\theta) > 0.5 \tag{9.3.3}$$

(therefore an angle greater than $\sim 30°$) otherwise we would have:

$$F' > F_R \tag{9.3.4}$$

As we have already mentioned it, a system of concurrent coplanar forces is in static equilibrium when the resultant of all forces (and moments) is zero. Graphically, the end of the last force on the dyname representation coincides with the origin of the first force. Mathematically this can be written:

$$\left.\begin{aligned}\sum_{i=1}^{n} F_{x_i}=R_x=0\\ \sum_{i=1}^{n} F_{y_i}=R_y=0\end{aligned}\right\}\Rightarrow \vec{R}=\vec{0} \qquad (9.3.5)$$

A diagram representing such forces is named a "free body diagram" and is well known by college students as looking as following:

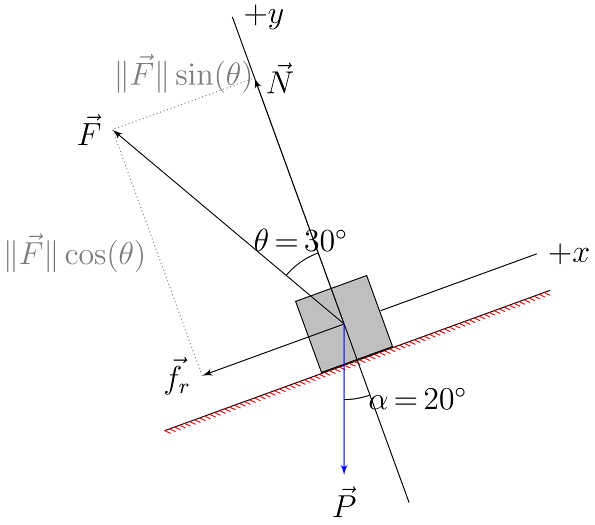

Figure 9.20: **Typical example of a free body diagram**

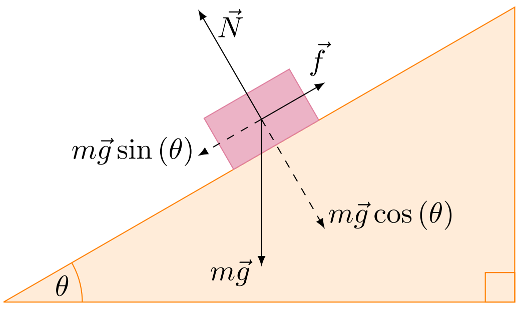
Or also as following:



We will meet and analyse quite a lot of such free body diagrams during the study of various subjects through this textbook (so don't be impatient to practice them...!).

D5. A material system $\mathcal{S}$ (set of material points (P_i, m_i)) is named "rigid solid" or "rigid body", or simply "solid", if the mutual distances of the constituent material points do not vary over time. What we note technically as follows:

$$\forall t, \forall (i,j): \quad \left\|\overline{P_iP_j}\right\| = c^{te} \qquad (9.3.6)$$

9.3.1 Newton's laws

Newton's three laws are the foundation for Classical Mechanics. They describe the relation between a body and the forces acting upon it, and its motion in response to those forces. These laws are retrospectively unprovable and can not be formalized (proved) because they result from observations and thus derive from our daily experience.

However, developments in modern physics and that are based on the consequences of these three laws are in such agreement with theoretical conditions that impose the principle of least action and relative experiences, that their validity could make any doubt (...).

9.3.1.1 Newton's first law (Inertia law)

Definition (#9.3.425): Any point or wide body mass perseveres in its shape (geometry) or its state of rest or of uniform motion (described by the center of mass), unless (in a static space-time[11]!) if "applied forces" force bring the body to change its shape or its movement.

$$\boxed{\vec{\Sigma} F=\vec{0} \Leftrightarrow \vec{v}=\vec{c^{te}}} \tag{9.3.7}$$

The punctual body is obviously dimensionless. It is a creation of the mind, a model representing a physical object that is animated as a translational motion (no rotation on itself because it is dimensionless!). We assume here that our physical space is three dimensional to which we add time that is not a spatial dimension in the context of Classical Mechanics but an immutable and independent parameter!

In other words: Every body at rest or in uniform motion is under pressure of a given number of zero forces or of a sum of forces whose resultant is zero (that is the fundamental principle of statics also named "principle of inertia")!

Corollary: When the trajectory of a body is not a straight line or when the speed of this body is not constant, we can conclude from the Principle of Inertia that the forces acting on this body do not cancel each other out.

Remarks

R1. We have proved this corollary in our study of Noether's theorem in the section of Analytical Mechanics at page 3132.

R2. Some people criticize the principle of inertia by arguing that there are not such possible experimental configuration in the Universe where a body has zero forces (or a zero resultant) on it as there is gravitation everywhere and that latter is a force! But these people forget that Albert Einstein has proved that gravity is NOT a force (as we will prove it during our study of General Relativity on page 5720.

In this corollary (and also before), comes to us in full light the word "force $\vec{F}$". Let us questioning this word for which everyday language is full of different meanings: wrist force, soul's force, think force... Also, the force can be visible or not, measurable or not depending on the case... Anyway, it has the "power" to change the path (the movement) and shape (geometry) of things. Without ignoring this halo that surrounds the word that has puzzled more than a physicist before him, Newton gives the force a very precise meaning, that stands out from the intuitive idea of a physical effort.

---

[11] Energy isn't conserved in an expanding or contracting space as we will prove it during our study of Noether theorem (see page 3136).

Let us give some intuitive properties of a force:

P1. The force is a vector quantity (see section Vector Calculus page 1797) with corresponding mathematical properties.

P2. The effect of a force, does not change if we slide the force on his line of action.

P3. The force is proportional to the mass.

Caution! Strictly speaking, force is not a vector. Like momentum, it is a covector or one-form, and covariant. You can see this in several ways:

- From the principle of virtual work: force is a linear function mapping infinitesimal displacements $\delta\vec{x}$ (a vector) to infinitesimal changes in energy $F\delta\vec{x}$ (a scalar) and hence a covector by definition.
- From Newton's second law $\vec{F}=m\vec{a}$ we see that the acceleration is a vector, which is "index-lowered" by the mass to give the covector that is the force.
- Conservative forces arise from the differential of potential energy $F=-\mathrm{d}U$, and the differential of a function is a one-form (covariant).

The difference between a vector and covector may not make sense if you're just starting to learn about physics, and for now, knowing that forces can be "added tip to tail" like vectors may be enough for practical calculations. But it is something you should start to pay attention to as your understanding matures: like dimensional analysis, carefully keeping track of what your physical objects are, mathematically, is helpful both for building deeper understanding, and catching errors.

A force is therefore a physical quantity manifested by its effects:

E1. "Dynamic effect": a force is capable of producing a cause or alter the movement of a body.

E2. "Static effect: a force is a cause capable of producing a deformation of the shape (geometry) of a body.

Any force can be represented by a vector whose four properties are at least:

P1. "Direction": the line in that the action takes place (this include the angle).

P2. "Orientation": The way the line in which the action takes place is followed.

P3. "Application point": the point where the action is applied on the body.

P4. "Intensity": the amplitude (norm) of the force

The photo below is an example of Newton's first law (an object in motion or at rest tends to stay in motion or at rest). The object in this picture is the man, and even though his bike stopped, he kept moving forward (...):

It is possible to classify most of the forces by families such as:

F1. The "forces of reaction": each body applies a force on another body that is in contact with himself. For example, if an object is putted on a table, this table applied (most of time...) an equal and opposite force on the object (so that it does not sink into the table - that are quantum mechanisms that are responsible for this reaction force). This force is always vertical to the point of contact.

F2. The "frictional forces" the frictional force exists when two bodies are in contact. It always opposes to the movement. The friction force which opposes to the movement has not only has a negative effect, it is also essential to ensure contact between two surfaces (e.g. contact of tires with the road, brake, etc.).

F3. The "tension forces": it is a force that pulls on an element of a body such as the tension exerted by a thread or a spring (see section Mechanical Engineering page 3416).

F4. The "action-at-a-distance forces": these are the forces that act through vector fields such as electric field, magnetic field or gravitational field (types of forces that result even when the two interacting objects are not in physical contact with each other, yet are able to exert a push or pull despite their physical separation). This last type of common force has the particularity, if the field is isotropic, to be reduced to the study of the body's center of gravity (we will prove it further below during our study of static forces).

Remark

As far as we know the are no official conventions for a finite number of properties for forces and for categories of forces. In some books the authors will tell you that there are only two type of forces: Contact Forces (frictional forces, tension forces, normal forces, air resistance forces, applied forces, spring forces, etc.) and Action-at-a-Distance Forces (gravitational force, electric force, magnetic force).

9.3.1.2 Newton's second law (Fundamental Principle of Dynamics)

Definition (#9.3.426): The change in motion is proportional to the "hard driving force", and is carried along the line through which this force is printed. Or more precisely: The acceleration of an object as produced by a net force is directly proportional to the magnitude of the net force, in the same direction as the net force, and inversely proportional to the mass of the object.

A force, we know it, is in the language of Newton what causes the "change of the movement" and not something else...! But, supplement to the program, the words "change of motion" of the law hide a mathematical meaning, different from the intuition "variation in speed". For Newton, we saw that a body at rest was characterized by its quantity of matter, its mass. Inspired by some predecessors, Newton put that a body in motion "carries a certain amount", simply named at his time: the "linear momentum". This is actually this amount which, under the simple word "movement", is contained in the statement of the second law. The amount of movement is the measure that we derive from both speed (concept which we will define later in our study of the kinematics) and quantity of matter, that is, by definition, the product of its mass by its speed:

$$\boxed{\vec{p}=m\vec{v}} \tag{9.3.8}$$

The reader may have noticed that linear momentum is as for the force, a convector and not a vector!

Caution! The linear momentum relation $p=mv$ doesn't apply to particles without mass. However such particles can transfer momentum and we will explain and prove that during our study of Special Relativity (see page 5627).

Using modern mathematical symbols, the first part of this second law can then be reformulated:

The force is equal to the variation with time of the amount of movement or in a non-relativistic framework:

$$\vec{F}=\frac{\mathrm{d}\vec{p}}{\mathrm{d}t}=\frac{\mathrm{d}(m\vec{v})}{\mathrm{d}t}\cong m\frac{\mathrm{d}(\vec{v})}{\mathrm{d}t}=m\vec{a} \tag{9.3.9}$$

This latter relation is valid until the speed is much lower than that of light as we will see in our study of Special Relativistic much later, as Newton supposed that the mass did not vary (or do not seem to vary...) as a function of speed. Thus, the "fundamental relation of dynamics (FRD)" is also given by:

$$\boxed{\vec{F}=m\vec{a}} \tag{9.3.10}$$

and can be stated as follows: Given a constant mass m of a body, the acceleration experienced by a body in an inertial frame is proportional to the net force it undergoes, and inversely proportional to its mass m in a non relativistic framework. The law addresses the cause and effect relationship between force and motion and the classical sense (as far as we know, in this early 121st century - holocene calendar -, in many Quantum Physics effects, causality doesn't exist as we will prove it during our study of the subject later). So it may be useful that we define now these both concepts in the context of our modern physical comprehension of the observable Universe.

Remark

Notice the interesting following relationship with the delta Dirac function (see section Differential and Integral Calculus page 1569):

$$\Delta\int\limits_{-\infty}^{+\infty} F(t)\mathrm{d}t=\int_{-\infty}^{+\infty} mv\delta(t)\mathrm{d}t \tag{9.3.11}$$

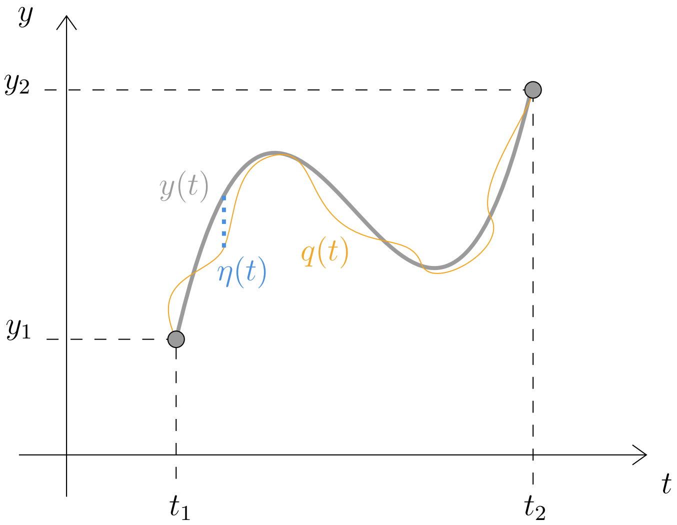
Typical apparatus (PASCO® scientific) used in high schools to verify Newton's second law with a dynamic system and a smart cart:

PASCO wireless smart cart

Let us see now that we can prove $F=ma$ using the Maupertuis principle (i.e. principle of least action) as introduced in the section of Analytical Mechanics at page 3152.

For this we imagine a body travelling a path that can be describe by a function of time $y(t)$. We add at every moment t a small perturbation $\eta(t)$, let us note this new perturbated path:

$$q(t)=y(t)+\eta(t) \tag{9.3.12}$$



And since the variations are small, the difference in action between these two paths is 0, i.e.:

$$\delta S = S[q(t)] - S[y(t)] = 0 \tag{9.3.13}$$

Our next task is to solve this equation. So we compute the action for each path. For this, we need the kinetic and potential energy for each, and we write them as a function of y and η.

We have for that path $q(t)$:

$$\begin{aligned} T(q) &= \frac{1}{2}mv^2 & V &= V(q) \\ &= \frac{1}{2}m\left(\frac{\mathrm{d}q}{\mathrm{d}t}\right)^2 & V(q) &= V(y+\eta) \\ &= \frac{1}{2}m\left(\frac{\mathrm{d}}{\mathrm{d}t}(y+\eta)\right)^2 & V(q) &= V(y)+\eta V'(y)+\eta^2V''(y)+\ldots \\ &= \frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2+m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}+\frac{1}{2}m\left(\frac{\mathrm{d}\eta}{\mathrm{d}t}\right)^2 & V(q) &\cong V(y)+\eta V'(y) \\ &\cong \frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2+m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t} \end{aligned} \tag{9.3.14}$$

and for the path $y(t)$:

$$\begin{aligned} T(y) &= \frac{1}{2}mv^2 & V = V(y) \\ &= \frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2 \end{aligned} \tag{9.3.15}$$

Therefore for the path $q(t)$ we have:

$$\begin{aligned}S[q(t)]&=\int\limits_{t_1}^{t_2}(T(q)-V(q))\mathrm{d}t\\&=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2+m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}-V(y)-\eta V'(y)\right)\mathrm{d}t\\&=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2-V(y)\right)\mathrm{d}t+\int\limits_{t_1}^{t_2}\left(m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}-\eta V'(y)\right)\mathrm{d}t\end{aligned} \tag{9.3.16}$$

and for the path $y(t)$:

$$S[y(t)]=\int\limits_{t_1}^{t_2}(T-V)\mathrm{d}t=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2-V(y)\right)\mathrm{d}t \tag{9.3.17}$$

Hence:

$$\begin{aligned}&\delta S=S[q(t)]-S[y(t)]\\&=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2-V(y)\right)\mathrm{d}t+\int\limits_{t_1}^{t_2}\left(m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}-\eta V'(y)\right)\mathrm{d}t-\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}y}{\mathrm{d}t}\right)^2-V(y)\right)\mathrm{d}t\\&\int\limits_{t_1}^{t_2}\left(m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}-\eta V'(y)\right)\mathrm{d}t=0\end{aligned} \tag{9.3.18}$$

We can rewrite the first term in the parenthesis this further by using integration by parts:

$$\int\limits_{t_1}^{t_2}m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}\mathrm{d}t=m\frac{\mathrm{d}y}{\mathrm{d}t}\eta\Bigg|_{t_1}^{t_2}-\int\limits_{t_1}^{t_2}m\frac{\mathrm{d}^2y}{\mathrm{d}t^2}\eta\mathrm{d}t \tag{9.3.19}$$

The first right hand term cancel as at the starting point t_1 we have η that is zero and same for the final point t_2 where η is zero. Therefore:

$$\int\limits_{t_1}^{t_2}m\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\eta}{\mathrm{d}t}\mathrm{d}t=-\int\limits_{t_1}^{t_2}m\frac{\mathrm{d}^2y}{\mathrm{d}t^2}\eta\mathrm{d}t \tag{9.3.20}$$

Therefore:

$$\delta S=S[q(t)]-S[y(t)]=\int\limits_{t_1}^{t_2}\left(\left[-m\frac{\mathrm{d}^2y}{\mathrm{d}t^2}-V'(y)\right]\eta\right)\mathrm{d}t=0 \tag{9.3.21}$$

But since η can be just about anything, this can only be true if the parenthesis is zero:

$$-m\frac{\mathrm{d}^2y}{\mathrm{d}t^2}-V'(y)=0 \tag{9.3.22}$$

So what we found is that the action is minimal for the path that satisfies this curious differential equation. Now it might look complicated, but it's not.

Now it might look complicated, but it's not! Minus the derivative of the potential is just the force. And the second derivative of height? Well, that's just acceleration. Such that:

$$-ma+F(y)=0 \tag{9.3.23}$$

So if we rearrange this, we find that the path that satisfies the principle of least action is the one that obeys:

$$F=ma \tag{9.3.24}$$

In other words, the principle of least action is equivalent to Newton's second law!

Definitions (#9.3.427):

D1. A "cause" (also referred to as "causation", "causality", or "cause and effect[12]") is the influence by which one event, process or state (a cause) contributes to the production of another event, process or state (an effect) where the cause is totally or partly responsible for the effect, and the effect is totally or partly dependent on the cause.

D2. An "effect" is a change which is a result or consequence of an action, a physical cause or of an immaterial probability[13].

Caution! Newton's second law of motion is at the heart of Classical Mechanics. Like other stuffs, it is insubstantial. Yet clearly Newton's second law is full of meaning, by the highest standard: It proves itself useful in demanding situations. Splendid, unlikely looking bridges, like the Erasmus Bridge (known as the Swan of Rotterdam), do bear their loads; spacecraft do reach Saturn. The paradox deepens when we consider force from the perspective of modern physics. In fact, the concept of force is conspicuously absent from our most advanced formulations of the basic laws as we will prove it in the next chapters. It doesn't appear in the Schrödinger's equation, or in any reasonable formulation of Quantum Field Theory, or in the foundations of general relativity...

Remember that the "mass" is a measure for the quantity of material contained in a body (see section Principia page 3087). The mass is a quantity independent of where it is located (S.I.

---

[12] *Post hoc ergo propter hoc* (latin of "after this, therefore because of this:) is an informal fallacy that states: "Since event Y followed event X, event Y must have been caused by event X." It is often shortened simply to *post hoc fallacy*. A logical fallacy of the questionable cause variety, it is subtly different from the fallacy *cum hoc ergo propter hoc* ("with this, therefore because of this"), in which two events occur simultaneously or the chronological ordering is insignificant or unknown. Post hoc is a logical fallacy in which an event says to be the cause of a later event because it occurred earlier!

[13] All speculative Quantum Causal Models created so far until year 12017 (holocene calendar) have failed to find a deterministic causality to some Quantum effects that have well explained probabilistic behaviours! Thus it follows that the Kalâm cosmological argument fails because its first premise fails (but it also fails for the reason as we have already seen during our study of Logic that if in case there is a premise, either implicit or explicit, that is logically equivalent to the conclusion then the reasoning is said to be "circular". In many cases, circularity is a problem and we name such circularity a "vicious circularity".

unit kilogram: [kg]). The "weight" (the oldest trace differentiating mass and weight seems to date from the early 117st century by Newton), corresponds to the force (S.I. unit Newton: [N]) that an object applied on another one through an action (or field). The latter depends on where we are located (see below the equation of the gravitational force of Newton).

We will see (prove) that in the context of a body falling in a gravitational field with a spherical symmetry, we have see section Astronomy page 5255):

$$\vec{F}=m\vec{a}=m\left(\frac{GM}{R^2}\frac{\vec{R}}{\|\vec{R}\|}\right) \tag{9.3.25}$$

as part of our good old Earth, we have the habit to write:

$$\|\vec{a}\|=g \tag{9.3.26}$$

In an Eulerian system in Cartesian coordinates, a given quantity φ of a continuous medium will have a distribution based on four independent variables x, y, z, t. For small changes $\mathrm{d}x$, $\mathrm{d}y$, $\mathrm{d}z$ and $\mathrm{d}t$, the total variation φ being expressed by (see section Differential and Integral Calculus page 1466):

$$\mathrm{d}\varphi=\frac{\partial\varphi}{\partial x}\mathrm{d}x+\frac{\partial\varphi}{\partial y}\mathrm{d}y+\frac{\partial\varphi}{\partial z}\mathrm{d}z+\frac{\partial\varphi}{\partial t}\mathrm{d}t \tag{9.3.27}$$

By following a particle in its motion, we observe during a time $\mathrm{d}t$ displacements $\mathrm{d}x$, $\mathrm{d}y$, $\mathrm{d}z$. We can therefore express from the previous relation of the total variation of φ for the time $\mathrm{d}t$. We obtain therefore the expression of a very important derivative in theoretical physics named the "particular derivative":

$$\frac{\mathrm{d}\varphi}{\mathrm{d}t}=\frac{\partial\varphi}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial\varphi}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial\varphi}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial\varphi}{\partial t} \tag{9.3.28}$$

In Classical Mechanics we will particularly work with the Newtonian gravitational field. Therefore, the relation linking the force to the acceleration takes a more general form. Let's see how!

Given the particular derivative of the velocity (for the three spatial coordinates):

$$\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\partial\vec{v}}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial t} \tag{9.3.29}$$

Which can also be written:

$$\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\partial\vec{v}}{\partial t}+v_x\frac{\partial\vec{v}}{\partial x}+v_y\frac{\partial\vec{v}}{\partial y}+v_z\frac{\partial\vec{v}}{\partial z} \tag{9.3.30}$$

Which can also be written in condensed form:

$$\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\partial\vec{v}}{\partial t}+(\vec{v}\circ\vec{\nabla})\vec{v}=\left(\frac{\partial}{\partial t}+\vec{v}\circ\vec{\nabla}\right)\vec{v} \tag{9.3.31}$$

The Newton's second law is written then in generalized form:

$$\boxed{\vec{F}=m\left(\frac{\partial}{\partial t}+\vec{v}\circ\vec{\nabla}\right)\vec{v}} \tag{9.3.32}$$

where as we will see it during our study of fluid dynamics (see section Continuous Mechanics page 3830):

$$\vec{v} \circ \vec{\nabla} \tag{9.3.33}$$

is the "advection term".

This formulation of Newton's second law is of utmost importance in physics. It makes explicit account of the force experienced by a material point in a vector field depending on the speed and not only of the position. We will use this formulation in the section of Continuum Mechanics in our study of fluids and plasmas (see page 3945), in the section of Electromagnetism and in that of General Relativity (see page 5720)!

We can see that if $\vec{\nabla}(\vec{v}) = \vec{0}$, that is to say if the gradient of the velocity field is zero (i.e. the velocity field is constant or equal to zero - the latter case being typical for any experience outside a force field like a gravitational one for example!), then we fall back on the special case of the simple second Newton law as:

$$\vec{F} = m\left(\frac{\partial}{\partial t} + \vec{v} \circ \vec{\nabla}\right)\vec{v} = m\frac{\partial}{\partial t} + \underbrace{\vec{v} \circ \vec{\nabla}(\vec{v})}_{=0} = m\frac{\partial \vec{v}}{\partial t} = m\vec{a} \tag{9.3.34}$$

As we will prove during our study of Fluid Mechanics, the generalized Newton's second law can be written:

$$\vec{F} = m\frac{\partial \vec{v}}{\partial t} + m\vec{v} \circ (\vec{\nabla}\vec{v}) = m\frac{\partial \vec{v}}{\partial t} + m\frac{1}{2}\vec{\nabla} \cdot v^2 + (\vec{\nabla} \times \vec{v}) \times \vec{v} \tag{9.3.35}$$

In the case of a normal uniform gravitation field the last term vanish ("vorticity" as we will see it again during our study of Fluid Mechanics at page 3837), then it remains:

$$\vec{F} = m\frac{\partial \vec{v}}{\partial t} + m\frac{1}{2}\vec{\nabla} \cdot v^2 \tag{9.3.36}$$

That is to say in the one dimensional case this reduces to:

$$F = ma + \frac{\partial}{\partial x}\left(\frac{1}{2}mv^2\right) \tag{9.3.37}$$

And as we will see later the last term between parenthesis is the Kinetic Energy. Therefore:

$$F = ma + \frac{\partial}{\partial x}E_c \tag{9.3.38}$$

But as variation of the kinetic energy is in absolute value equal to that of the variation of potential energy, denoted E_p and sometimes U, on the same distance as we will prove later then we have:

$$\boxed{F = ma + \frac{\partial}{\partial x}U} \tag{9.3.39}$$

That means once again that if we are far away from any force field (gravitational one for example in Classical Mechanics), the latter relation reduce to the simple Newton's second law again as $U = 0$:

$$F = ma + \frac{\partial}{\partial x}\underbrace{U}_{=0} = ma \tag{9.3.40}$$

so if we see a body that accelerates it can only be due to an impulse (a direct applied force on it).

If there is nobody or nothing entering in collision on with our body or applying an impulse on it but we see that our body accelerates, then it mean that we are in the presence of a force field and the generalized Newton's second law reduced to:

$$F=m\underbrace{a}_{=0}+\frac{\partial}{\partial x}U=\frac{\partial}{\partial x}U \tag{9.3.41}$$

That is implicitly... a force due to a gravitational field (we still omit the case of electric field at this level).

But of course we can have the both terms that are non-zero! That is when a body accelerates because of an impulse plus because of a force field like the gravitation field (typically a rocket entering into orbit in a far away planet).

9.3.1.3 Newton's third law (Law of Action and Reaction)

Definition (#9.3.428): In every two-body static interaction, there is a pair of forces acting on the two interacting objects. The size of the forces on the first object equals the size of the force on the second object. The direction of the force on the first object is opposite to the direction of the force on the second object. Forces always come in pairs - equal and opposite action-reaction force pairs! This third law is most known under the name of "action / reaction principle" and follows from the first Newton law by mathematical through the reasoning that we have already seen during our study of Noether's theorem in the section Principles.

This law can be simply expressed in the following form:

$$\vec{F}_{12}=\vec{F}_{21} \tag{9.3.42}$$

Also sometimes written as:

$$\vec{F}_1=-\vec{F}_2 \qquad \text{or} \qquad \vec{F}_2=-\vec{F}_1 \tag{9.3.43}$$

and in a little bit more general and explicit way as following:

$$\boxed{\sum\vec{F}_{1\to 2}=\sum\vec{F}_{2\to 1}} \tag{9.3.44}$$

Thus, in nature, according to this principle, there is no isolated force, each force has its "opposite", they work in pairs!

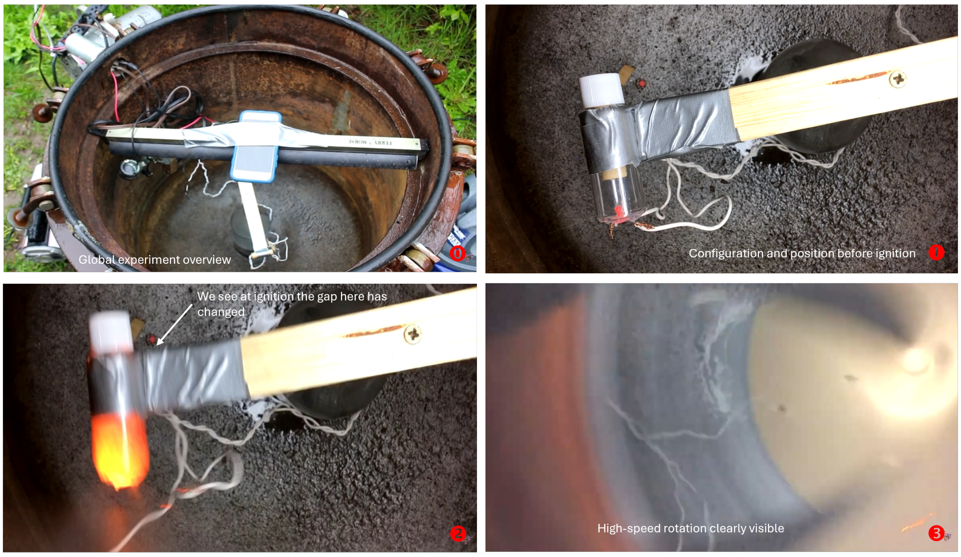
There is also a nice easy experiment (among many others) done by Cody Reeder that profs beyond reasonable doubt that a thruster also works in vacuum. Using his *Leader Iron Works Inc.* 189 [L] (50 gallons) vacuum/pressure vessel:

LEADER IRON WORKS INC.

that once connected to a vacuum pump looks like:

A coarse vacuum is created in the vessel of $-600\,[\text{mmHg}]$ (i.e. of $-0.789474\,[\text{atm}]$) so we have only 22% of the ambient normal pressure (corresponding approximately to the atmosphere pressure at an altitude of $11,000\,[\text{m}]$):

Now attaching an Estes 1/2A3-4T model rocket motor ($13\,[\text{mm}]$ engine) to a wooden board an igniting it we get:



Global experiment overview
⓪
Configuration and position before ignition
①
We see at ignition the gap here has changed
②
High-speed rotation clearly visible
③

and after ignition the coarse vacuum has obviously changed a little bit:

The same kind of experiment is visible in the video here https://www.youtube.com/watch?v=T8MOoUuLnug with a soda can hanged on a small wire instead of a miniature rocket thruster with still a coarse vacuum but however a better one of $-0.9\,[\text{atm}]$ corresponding approximately to an altitude of $16,000\,[\text{m}]$ (and we can see the action/reaction even before the can liquid hits the walls).

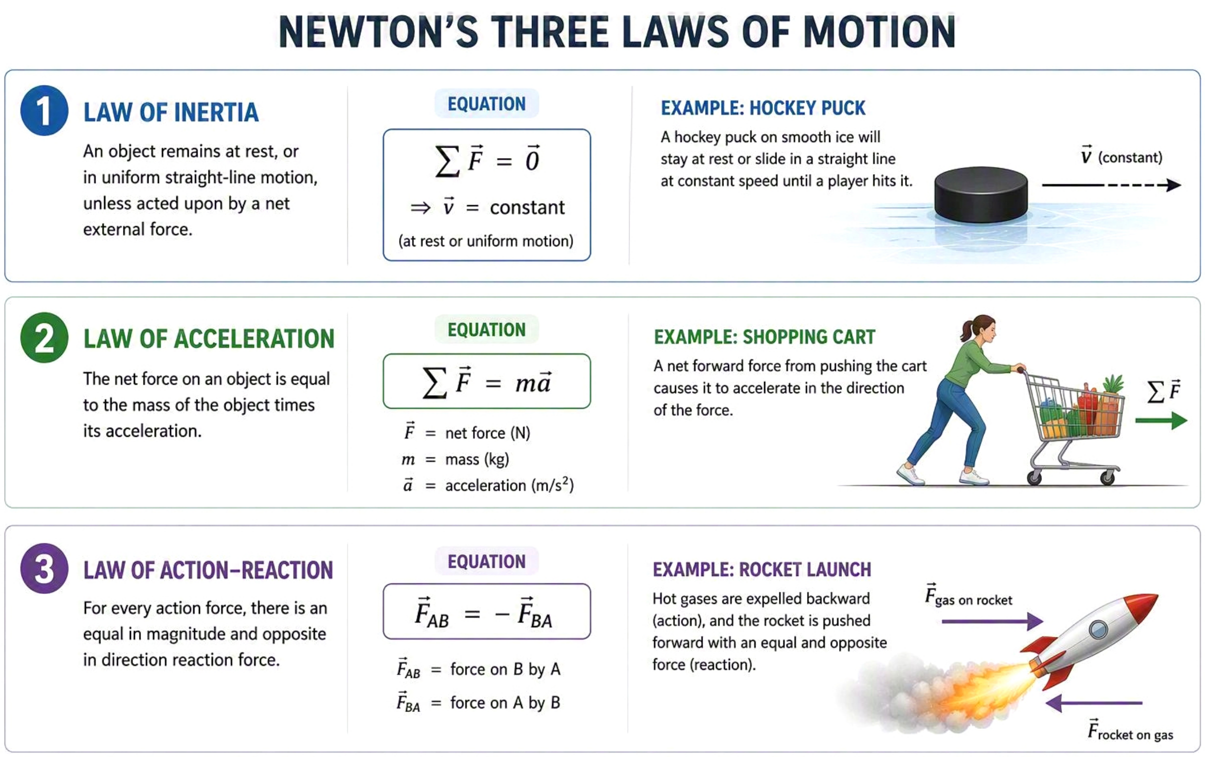
We can also say that two solid points or extended bodies in static contact exert on each other always opposing forces in direction but equal in intensity and direction.

It follows an important property of the third Newton law: For a material point, subject to forces $\vec{F}_1,\vec{F}_2,\ldots,\vec{F}_n$ to be in static equilibrium the resultant of the forces must be equal to zero. That is the material point:

$$\sum_{i=1}^{n}\vec{F}_i=\vec{0} \tag{9.3.45}$$

satisfies the "equilibrium condition".

The previous relation, which thus defines any body in equilibrium, opens the study of huge field of practical applications names "static forces" and that we will develop further below after having introduced the concept of force momentum.



NEWTON'S THREE LAWS OF MOTION

① **LAW OF INERTIA**

An object remains at rest, or in uniform straight-line motion, unless acted upon by a net external force.

EQUATION

$$\sum \vec{F} = \vec{0}$$

$$\Rightarrow \vec{v} = \text{constant}$$

(at rest or uniform motion)

EXAMPLE: HOCKEY PUCK

A hockey puck on smooth ice will stay at rest or slide in a straight line at constant speed until a player hits it.

② **LAW OF ACCELERATION**

The net force on an object is equal to the mass of the object times its acceleration.

EQUATION

$$\sum \vec{F} = m\vec{a}$$

$\vec{F}$ = net force (N)

m = mass (kg)

$\vec{a}$ = acceleration (m/s^2)

EXAMPLE: SHOPPING CART

A net forward force from pushing the cart causes it to accelerate in the direction of the force.

③ **LAW OF ACTION–REACTION**

For every action force, there is an equal in magnitude and opposite in direction reaction force.

EQUATION

$$\vec{F}_{AB} = -\vec{F}_{BA}$$

$\vec{F}_{AB}$ = force on B by A

$\vec{F}_{BA}$ = force on A by B

EXAMPLE: ROCKET LAUNCH

Hot gases are expelled backward (action), and the rocket is pushed forward with an equal and opposite force (reaction).

$\vec{F}_{\text{gas on rocket}}$
$\vec{F}_{\text{rocket on gas}}$

9.3.2 Center of Mass and Reduced Mass

The center of mass is a special case of the barycenter with all its properties that we have already largely developed in the section of Euclidean Geometry (therefore we strongly recommend to reader to refer to it at page 2635) but applied to physics.

We can make no distinction between "center of mass" and "center of gravity" (also named "centroid") if and only if the mass of the body is considered homogeneous.

For those who want a simple but impressive example of the importance of understanding the concept of center of gravity in the context of engineering and business, I recommend searching the Internet for video on the keyword "Steadicam". This is a technique of moving the center of gravity of cameras for image stabilization that has revolutionized the way of filming in the movie industry (and not only!). Or playing with center of mass can also be an art:

Definition (#9.3.429): Let us consider a solid formed of n mass points $m_1, m_2, \ldots, m_n$ and identified by their respective position vectors $\vec{r}_1, \vec{r}_2, \ldots, \vec{r}_n$. We name "center of mass" (or "center of inertia" if there is strict equality between gravitational mass and inertial mass) a point G where we can connect all the mass of the system (and therefore its analysis !!) and such that, the origin being arbitrarily chosen it is given by:

$$\vec{r}_G = \frac{\sum\limits_{i=1}^{n} \vec{r}_i m_i}{\sum\limits_{i=1}^{n} m_i} \tag{9.3.46}$$

Relation that has to be compared by the reader with the one of the barycenter that we get in the section of Euclidean Geometry:

$$\overrightarrow{\text{O}G} = \frac{\sum\limits_{i=1}^{n} \alpha_i \overrightarrow{\text{O}A_i}}{\sum\limits_{i=1}^{n} \alpha_i} \tag{9.3.47}$$

In an identical way, we define the "reduced mass" of the system by:

$$\boxed{\mu = \frac{\prod\limits_{i=1}^{n} m_i}{\sum\limits_{i=1}^{n} m_i}} \tag{9.3.48}$$

The reduced mass is the "effective" inertial mass appearing in the two-body problem of Newtonian Mechanics. It is a quantity which allows the two-body problem to be solved as if it were a one-body problem.

Theorem 9.2. Given two bodies, one with mass m_1 and the other with mass m_2, the equivalent one-body problem, with the position of one body with respect to the other as the unknown, is that of a single body of mass:

$$\mu=\frac{1}{\dfrac{1}{m_1}+\dfrac{1}{m_2}}=\frac{m_1m_2}{m_1m_2} \tag{9.3.49}$$

Proof 9.2.1. This relation can be derived using Newton's second law, i.e. the force exerted by body 2 on body 1:

$$\vec{F}_{12}=m_1\vec{a}_1 \tag{9.3.50}$$

and the force exerted by body 2 on body 1 is:

$$\vec{F}_{21}=m_2\vec{a}_2 \tag{9.3.51}$$

According to Newton's third law, the force that body 2 exerts on body 1 is equal and opposite to the force that body 1 exerts on body 2:

$$\vec{F}_{12}=\vec{F}_{21} \tag{9.3.52}$$

Therefore:

$$m_1\vec{a}_1=-m_2\vec{a}_2 \tag{9.3.53}$$

and:

$$\vec{a}_2=-\frac{m_1}{m_2}\vec{a}_1 \tag{9.3.54}$$

The relative acceleration $\vec{a}_{\text{rel}}$ between the two bodies is given by:

$$\vec{a}_{\text{rel}}=\vec{a}_1-\vec{a}_2=\left(1+\frac{m_1}{m_2}\right)\vec{a}_1=\frac{m_2+m_1}{m_1m_2}m_1\vec{a}_1=\frac{\vec{F}_{12}}{m_{\text{red}}} \tag{9.3.55}$$

So we conclude that body 1 moves with respect to the position of body 2 as a body of mass equal to the reduced mass.

■ Q.E.D.

If we consider the solid as continuous (true only at the microscopic scale in a first approximation) therefore it comes:

$$\vec{r}_G=\frac{\displaystyle\int_V \vec{r}\mathrm{d}m}{\displaystyle\int_V \mathrm{d}m} \tag{9.3.56}$$

Where the integrals are extended to whole solid volume.

Furthermore, if the solid is homogeneous (special case), of volumetric mass ρ, then $\mathrm{d}m = \rho \mathrm{d}V$, $\mathrm{d}V$ being the volume element. The equation can then be written (the notation of the triple integral is reduced to only one integral by for clarity purpose):

$$\boxed{\vec{r}_G = \frac{\displaystyle\int_V \vec{r}\mathrm{d}V}{\displaystyle\int_V \mathrm{d}V}} \tag{9.3.57}$$

That is to say in components:

$$x_G = \frac{\displaystyle\int x\mathrm{d}V}{V} \qquad y_G = \frac{\displaystyle\int y\mathrm{d}V}{V} \qquad z_G = \frac{\displaystyle\int z\mathrm{d}V}{V} \tag{9.3.58}$$

Properties:

P1. If the solid has an axis of symmetry, then G is on that axis.

P2. If the solid has a plane of symmetry, then G is on this plane.

P3. If the solid has several axes of symmetry, then G is at their intersection.

Remark

The center of mass M may be out of the solid (eg: a stool, a boomerang, etc.).

It is not always obvious to calculate the center of mass of a relatively simple given body. It's not that the mathematical tools to handle are complex (simple integral, Pythagoras theorem and some multiplication and integration by parts) but we must approach the problem in an elegant way and if we do not immediately the right approach we will fail very quick. We advise the teachers that address this topic and the related exercises to do it with their students (i.e. in class) but by leaving them to discuss how the teacher must attack the problem on the blackboard (it works very well).

9.3.2.1 Center of Mass Theorem

Under the action of external forces $\vec{F}_1, \ldots, \vec{F}_i, \ldots, \vec{F}_n$, acting at each point of a solid, each of these points takes an acceleration equal to the applied force $\vec{F}_i$. Using Newton's second law for each point and summing the effects we have (in a non-relativistic case):

$$\vec{F}_{\text{ext}} = \sum_{i=1}^{n} F_i = \sum_{i=1}^{n} F_i = \sum_{i=1}^{n} m_i \frac{\mathrm{d}^2\vec{r}_i}{\mathrm{d}^2 t} = \frac{\mathrm{d}^2}{\mathrm{d}t^2} \sum_{i=1}^{n} m_i \vec{r}_i \tag{9.3.59}$$

by the position of the center of mass given by the relation:

$$\vec{r}_G = \frac{\displaystyle\sum_{i=1}^{n} \vec{r}_i m_i}{\displaystyle\sum_{i=1}^{n} m_i} \tag{9.3.60}$$

In the special case of a binary system (used a lot in Astronomy and Corpuscular Quantum physics as we will see it) we have:

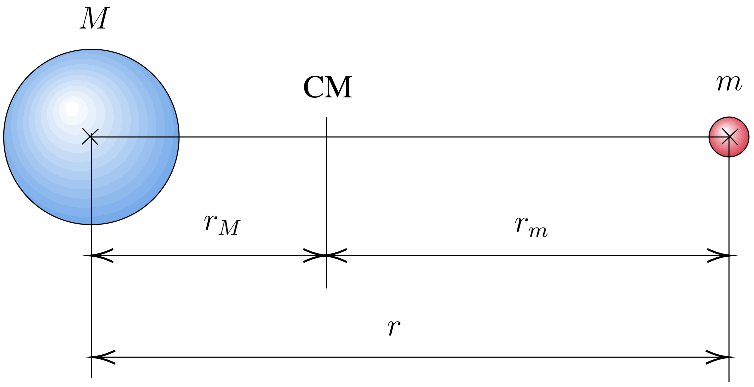


Figure 9.21: **Binary system center of mass (profile view)**

Where:

$$\vec{r}_G=\frac{M\vec{r}_M+m\vec{r}_m}{M+m} \tag{9.3.61}$$

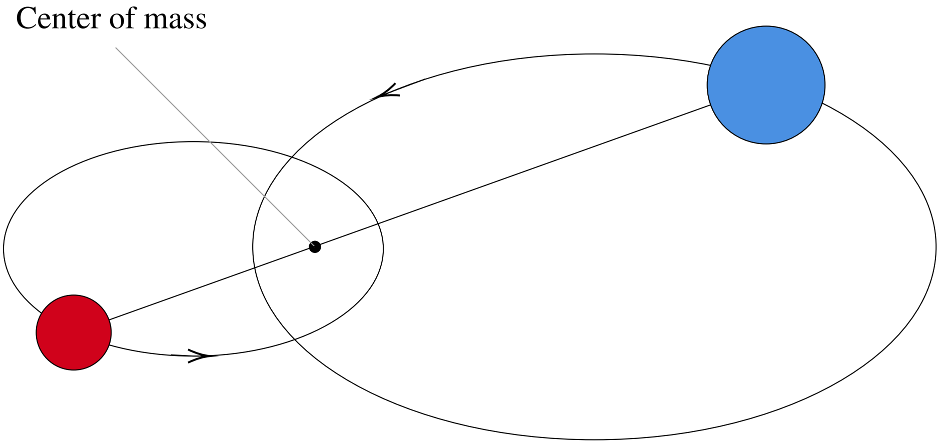

Figure 9.22: **Binary system center of mass when in motion**

In the special case where $M=m$ we have obviously:

$$\vec{r}_G=\frac{m\vec{r}_M+m\vec{r}_m}{2m}=\frac{\vec{r}_M+\vec{r}_m}{2} \tag{9.3.62}$$

Therefore the center of mass (CM) is indeed at the middle point!

If we set the position of the center of mass at the origin ($\vec{r}_G=\vec{0}$). Then we have in the case where $M\neq m$:

$$M\vec{r}_M+m\vec{r}_m=\vec{0} \tag{9.3.63}$$

and then we have taking the norm:

$$\frac{M}{m}=-\frac{r_m}{r_M} \tag{9.3.64}$$

In other words, the distances r_M and r_M can change, but the ratio r_m/r_M is fixed. Also, the center of mass always lies on the line connecting the two stars.

To come back to the general case, it comes if the repository is placed on the center of mass:

$$\vec{F}_{\text{ext}}=\frac{\mathrm{d}^2\vec{r}_G}{\mathrm{d}t^2}\sum_{i=1}^{n}m_i \tag{9.3.65}$$

where:

$$\sum_{i=1}^{n}m_i=M \tag{9.3.66}$$

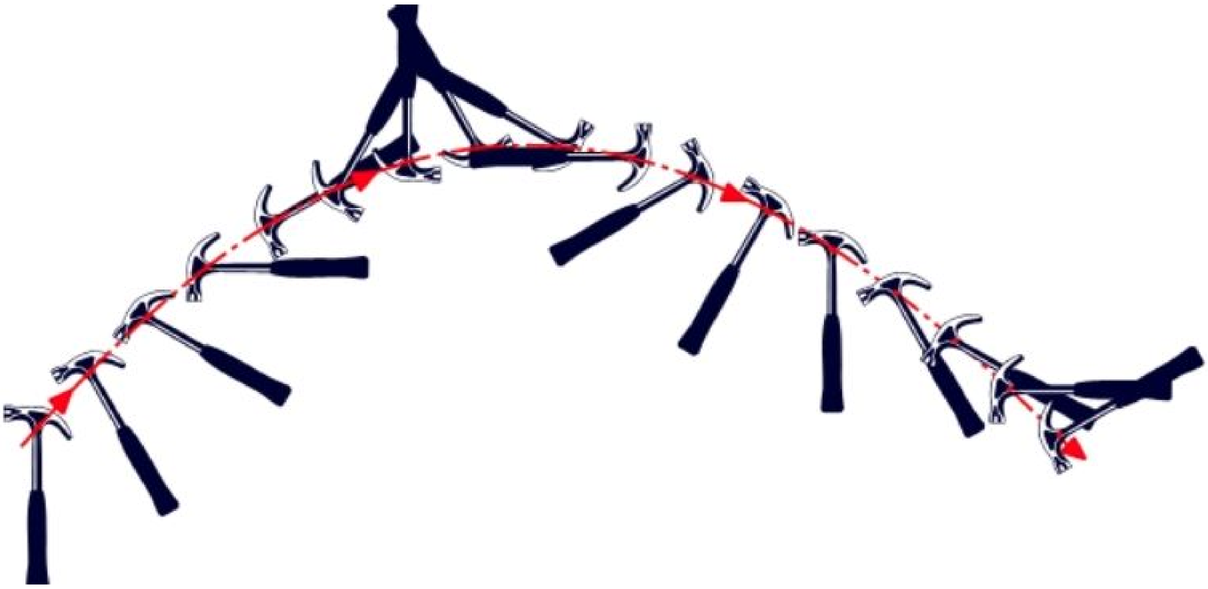
therefore:

$$\boxed{\vec{F}_{\text{ext}}=M\frac{\mathrm{d}\vec{r}_G}{\mathrm{d}t}=M\vec{a}_G} \tag{9.3.67}$$

This is the theorem of the center of mass that we can state as follows:

The center of mass of a solid moves as a material point of mass equal to that of the solid and on which would be applied the sum of external forces. A simple example is that of an explosive projectile in absence of gravity describing a curved path. If the projectile explodes and breaks, the shards of the center of mass continues to describe the curved path he had started.

Or another famous example:



Remark

In the particular case of a solid (set of points) subjected to the field of gravity, $\vec{F}_{\text{ext}}$ is the weight of the solid and then G is named the "center of gravity" (hence the origin of this name).

Let us come back on the relation:

$$\vec{r}_G=\frac{\sum\limits_{i=1}^{n}\vec{r}_i m_i}{\sum\limits_{i=1}^{n} m_i} \tag{9.3.68}$$

giving the position of center of mass. Its speed is:

$$\vec{v}_G=\frac{\mathrm{d}\vec{r}_G}{\mathrm{d}t}=\frac{1}{M}\sum_i\frac{\mathrm{d}\vec{r}_i}{\mathrm{d}t}=\frac{1}{M}\sum_i m_i\vec{v}_i=\frac{1}{M}\sum_i\vec{p}_i \tag{9.3.69}$$

By denoting:

$$\vec{P}=\sum_i\vec{p}_i \tag{9.3.70}$$

where $\vec{P}$ is the linear momentum of the system, it comes:

$$\vec{P}=M\vec{v}_G \tag{9.3.71}$$

This relation shows that if the sum of the external forces is zero then:

$$\vec{F}_{\text{ext}}=\frac{\mathrm{d}\vec{P}}{\mathrm{d}t}=\vec{0}\Rightarrow\vec{P}=\vec{c}^{te}\Rightarrow\vec{v_G}=\vec{c}^{te} \tag{9.3.72}$$

Thus the amount of movement of the entire system is conserved and movement of the system center of mass is unaltered. This justifies the remarks made during the study of the conservation of momentum.

In the study of interactions between particles, it is often convenient to use a reference frame linked to the center of mass of all particles. This center of mass is at rest in that frame, its speed is zero and also the total linear momentum, as shown by the above equations. This property is the powerful benefit of this description.

Remark

In mechanics, the use of the center of mass (material point) is particularly easy because the system of forces is only governed by the Newton's law. With electric charged particles, it is quite different. Electromagnetic effects are dominant in their acceleration, which induces interactive wave phenomena significantly more complex. That is why we will never see a study in this textbook of "charge center" when we will get in the section of Electrostatic or Electrodynamics...

✍**Example:**

We want to determine how far the center of mass of the Earth-Moon system is from the center of Earth by ignoring the other objects in our Solar System.

We define the origin of the coordinate system as the center of Earth. Then, with just two objects, then the center of mass theorem will be written:

$$r_G=\frac{\sum\limits_{i=1}^{2} r_i m_i}{\sum\limits_{i=1}^{2} m_i}=\frac{M_{\text{Earth}} r_{\text{Earth}}+M_{\text{Moon}} r_{\text{Moon}}}{r_{\text{Earth}}+r_{\text{Moon}}} \tag{9.3.73}$$

But as we choose the center of Earth as the origin, we then have $r_{\text{Earth}}=0$ [m]. Inserting this into the equation for r_G gives:

$$r_G=\frac{M_{\text{Moon}} r_{\text{Moon}}}{r_{\text{Earth}}+r_{\text{Moon}}} \cong \frac{7.36 \cdot 10^{22} \cdot 3.82 \cdot 10^5}{5.97 \cdot 10^{24}+7.36 \cdot 10^{22}} \cong 4.64 \cdot 10^6 \text{ [m]} \tag{9.3.74}$$

The radius of Earth is $6.37 \cdot 10^6$ [m] , so the center of mass of the Earth-Moon system is approximately $1,730$ [km] below the surface of Earth.

9.3.2.2 Guldin's Theorem

The "Guldin's Theorems" or also named "Pappus's Centroid Theorem" gives the possibility in some cases to simplify the calculation of the center of mass of some bodies (or reciprocally the volume or surface when the coordinates of the center of mass is known).

1. First Theorem:

   Theorem 9.3. The volume V of a solid of revolution generated by rotating a plane figure F about an external axis is equal to the product of the area S of F and the distance d travelled by its geometric centroid.

   Proof 9.3.1. Given a flat plate, homogeneous, of constant thickness e, of volumetric density ρ placed in a Cartesian plane $x\text{O}y$. We know that we have compared to the y-axis:

$$y_G=\frac{\displaystyle\int \mathrm{d}m}{\displaystyle\int m}=\frac{\displaystyle\int y\mathrm{d}m}{M}=\frac{e\rho\displaystyle\int y\mathrm{d}S}{e\rho S}=\frac{\displaystyle\int \mathrm{d}S}{S} \tag{9.3.75}$$

   Therefore:

$$y_G\cdot S=\int \mathrm{d}S \tag{9.3.76}$$

   Let us consider now the following figure:

   Let us consider a rotation of $2\pi y$ around the x axis of small surface located on y following the vertical axis. The element of volume described by a surface element $\mathrm{d}S$ during this rotation is obviously equal to:

$$\mathrm{d}V=2\pi y\mathrm{d}S \tag{9.3.77}$$

and therefore, the total volume described by the complete surface S is using the previous relation:

$$V=\int \mathrm{d}V=2\pi\int \mathrm{d}S=2\pi y_G S \tag{9.3.78}$$

Thus, by doing the same for x_G, we finally get:

$$y_G=\frac{V}{2\pi S} \qquad x_G=\frac{V}{2\pi S} \tag{9.3.79}$$

■ Q.E.D.

✍**Example:**

For example, the volume of the torus (see section Geometric Shapes page 2848) with minor radius r and major radius R is:

$$V=(\pi r^2)(2\pi R)=2\pi^2 Rr^2 \tag{9.3.80}$$

2. Second Theorem (or first depends on the point of view...):

Theorem 9.4. The surface area S of a surface of revolution generated by rotating a plane curve C about an axis external to C and on the same plane is equal to the product of the arc length L of C and the distance d travelled by its geometric centroid.

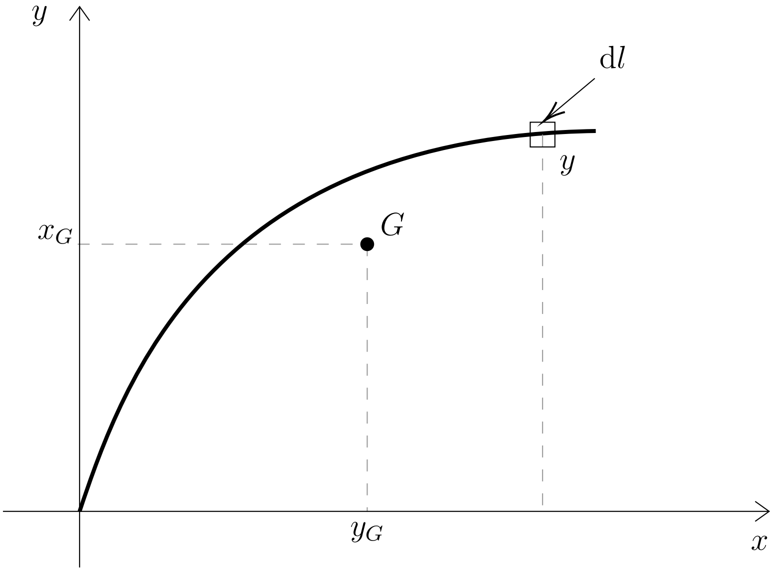
Proof 9.4.1. Let us consider a curved path or string, homogeneous, of length L, of constant section and of linear mass density ρ_l. We know that we have compared to the y-axis:

$$y_G=\frac{\displaystyle\int y\mathrm{d}m}{\displaystyle\int \mathrm{d}m}=\frac{\rho_l\displaystyle\int y\mathrm{d}l}{\rho_l L}=\frac{\displaystyle\int y\mathrm{d}l}{L} \tag{9.3.81}$$

and therefore:

$$y_G L=\int y\mathrm{d}l \tag{9.3.82}$$

Let us consider now the following figure:



Let us consider a rotation around the x axis. The surface described by an element of length $\mathrm{d}l$ during this rotation is equal to:

$$\mathrm{d}V=2\pi\mathrm{d}l \tag{9.3.83}$$

and therefore the total area described by the string of length L is:

$$S=\int\mathrm{d}S=2\pi\int y\mathrm{d}l=2\pi y_G L \tag{9.3.84}$$

Thus, by doing the same for x_G, we finally get:

$$y_G=\frac{S}{2\pi L}\qquad x_G=\frac{S}{2\pi L} \tag{9.3.85}$$

■ Q.E.D.

✍**Example:**

For example, the surface area of the torus (see section Geometric Shapes page 2848) with minor radius r and major radius R is:

$$A=(2\pi r)(2\pi R)=4\pi^2 Rr \tag{9.3.86}$$

9.3.3 Kinematics of Rectilinear Motion

If a phenomenon is evolving, by observing it, we see a shift from the concrete value of one or more characteristic variables. These values are obviously not constant but variable. An evolution implies that there is a beginning, an infinite number of intermediate states and an end.

Definition (#9.3.430): A "state" is the description of a snapshot of an evolving phenomenon (not necessarily in the temporal sense).

The functional relation between variables for a given state can be described by an equation. For an evolutionary phenomenon, there may be an infinite number of states that we can describe by as many equations. In this form, it has no interest. We are looking for a single equation that relates the different quantities verifying all the states that the evolutionary phenomenon may admit. By this equation, we can then calculate any state of the evolutionary phenomenon studied: this is the "equation of state" (a concept taken from the section of Thermodynamics).

Therefore kinematics is the branch of Classical Mechanics which describes the motion of points (alternatively "particles"), bodies (objects), and systems of bodies without consideration of the masses of those objects nor the forces that may have caused the motion.

Kinematics begins with a description of the geometry of the system and the initial conditions of known values of the position, velocity and or acceleration of various points that are a part of the system, then from geometrical arguments it can determine the position, the velocity and the acceleration of any part of the system. The study of the influence of forces acting on masses falls within the purview of kinetics.

Kinematics is obviously used in wide range of fields like astrophysics to describe the motion of celestial bodies and collections of such bodies. In mechanical engineering, robotics, and biomechanics kinematics is used to describe the motion of systems composed of joined parts (multi-link systems) such as an engine, a robotic arm or the skeleton of the human body.

We consider mainly three sub-domains of kinematics:

1. "Rectilinear kinematics" or "Translation kinematics" investigates laws of motion of objects along straight line without any reference to forces that cause the motion to change.
2. "Curvilinear kinematics" investigates lows of motion of objects in space in two and three directions without any reference to forces that cause the motion to change.
3. "Rotational kinematics" investigates lows of motion of objects along circular path without any reference to forces that cause the motion to change.

9.3.3.1 Position

Definition (#9.3.431): The "position" of an object is defined by its position vector which in the particular case of a three-dimensional space is given by:

$$\vec{r}=(x,y,z) \tag{9.3.87}$$

Obviously each coordinate of a moving object may vary in function of time as:

$$\vec{r}=(x(t),y(t),z(t)) \tag{9.3.88}$$

Rather than this notation rather heavy with parentheses ... physicists frequently note the position vector (or vector space) in the form of a vector of 4 dimensions (three spatial components and one time component) and then we write:

$$\vec{r}=(x,y,z,t) \tag{9.3.89}$$

or simply denoted by:

$$\vec{r}(x,y,z,t) \tag{9.3.90}$$

and we then name it a "space-time four-vector" whose components are the generalized coordinates of the system.

9.3.3.2 Velocity and speed

Definition (#9.3.432): The "scalar velocity", also named "speed", denoted v, is defined as the distance travelled by an object during a given amount of time:

$$v=\frac{d}{t} \tag{9.3.91}$$

The SI unit for speed is obviously meter per second: $[\text{m}\cdot\text{s}^{-1}]$.

The latter must not be confused with the "velocity" that is the vectorial version of the speed defined as the displacement travelled by an object during a given amount of time:

$$\vec{v}=\frac{\vec{r}}{t} \tag{9.3.92}$$

✍**Example:**

A vehicle start its journey from a city A to go to a city B at a speed of $60\,[\text{km}\cdot\text{h}^{-1}]$ during one hour and comes back following the same way during the same duration of one hour. Therefore its average speed is:

$$\vec{v}=\frac{\Delta x}{\Delta t}=\frac{\text{total distance}}{\text{elapsed time}}=\frac{120}{2}=60\,[\text{km}\cdot\text{h}^{-1}] \tag{9.3.93}$$

and the average velocity is:

$$v=\frac{\vec{x}_{\text{final}}-\vec{x}_{\text{initial}}}{\Delta t}=\frac{\vec{0}-\vec{0}}{2}=0\,[\text{km}\cdot\text{h}^{-1}] \tag{9.3.94}$$

When a body is in uniform motion, that is to say, it travels a given distance following a dimension x_i with $i=\{1,2,3\}$ in a time always equal, the previous ratio is constant in time:

$$v_i=\frac{x_i}{t}=c^{te} \tag{9.3.95}$$

The "arithmetic average speed" or "average linear speed" is defined as the ratio of the distance between a given starting point $x_{i,0}$ at instant t_0 and an end point $x_{i,f}$ at a time t_f:

$$\bar{v}_i=\frac{x_{i,f}-x_{i,0}}{t_f-t_0}=\frac{x_i(t_f)-x_i(t_0)}{t_f-t_0}=\frac{\Delta x}{\Delta t}=c^{te} \tag{9.3.96}$$

Remark

You must take care when calculation the average speeds of as there are several types of averages in mathematics... (see section Statistics page 546)! For example, it is common to use the harmonic mean speed as we prove it in the section Statistics.

This represents an average (because we are not interested to know how the path between $x_{i,f}$ and $x_{i,0}$ has been travelled) but not the instantaneous speed of the vehicle at any given time.

If we want to know the speed named "instantaneous speed" of the vehicle at a point of its trajectory must take the limit of the delta time Δt to a differential element $\mathrm{d}t$ (see section Differential and Integral Calculus page 1464) as:

$$\mathrm{d}t=t_f-t_0=(t_0+\varepsilon)-t_0 \tag{9.3.97}$$

with $\varepsilon\to 0$.

Mathematically, we note this correctly as follows:

$$\mathrm{d}t=\lim_{\varepsilon\to 0}(t_0+\varepsilon)-t_0 \tag{9.3.98}$$

Thus, during an infinitely small time difference, the distance difference will also be infinitesimal. So we have:

$$\mathrm{d}x_i=\lim_{\varepsilon\to 0}(x_{i,0}+\varepsilon)-x_{i,0} \tag{9.3.99}$$

and finally:

$$\boxed{v_i=\frac{\mathrm{d}x_i}{\mathrm{d}t}=\dot{x}} \tag{9.3.100}$$

The junior engineer or scientist must be careful when calculating the average velocity. Indeed as we have prove it in the section of Statistics, the harmonic average has to be used and not the arithmetic average!!!

If the studied body is not in linear motion in three-dimensional Cartesian coordinate then its position will be given by the vector (x,y,z) and we will denote its velocity by:

$$\vec{v}=\left(\frac{\mathrm{d}x}{\mathrm{d}t},\frac{\mathrm{d}y}{\mathrm{d}t},\frac{\mathrm{d}z}{\mathrm{d}t}\right)=(v_x,v_y,v_z)=(\dot{x},\dot{y},\dot{z}) \tag{9.3.101}$$

Remark

If all the parts of a body moving at the same speed and in the same direction, then we have a "translation movement". By cons, in a "rotational movement", the speeds of the various body parts are not the same, in amplitude and in direction (we will see it further below in details), and may vary over time.

Caution! A movement can only be described scientifically with respect to a documented fixed reference point: the absolute motion does not exist. Galileo had already understood that: "*The movement is as nothing.*" The movement does not exist in itself, but in relation to something else.

Here is a non-exhaustive list of some typical speed magnitudes (the years are given relatively to the holocene calendar):

Magnitude $[\mathrm{m}\cdot\mathrm{s}^{-1}]$	**Magnitude** $[\mathrm{km}\cdot\mathrm{h}^{-1}]$	**Description**
$2.2\cdot 10^{-18}$	$7.8\cdot 10^{-18}$	Expansion rate between two points in free space 1 meter apart under Hubble's law
$1.4\cdot 10^{-14}$	$5\cdot 10^{-14}$	Cave of the Crystals gypsum crystals' growth rate
$1\cdot 10^{-13}$	$3\cdot 10^{-13}$	Rate of erosion of bedrock
$4.12\cdot 10^{-12}$	$1.48\cdot 10^{-11}$	Average growth rate of a limestone stalactite
$9.8\cdot 10^{-11}$	$3.5\cdot 10^{-10}$	Rate of global sea level rise in between 11993–12003 (approx. 3.1 $[\mathrm{mm}\cdot\mathrm{year}^{-1}]$)
$8\cdot 10^{-9}$	$5\cdot 10^{-8}$	Typical magnitude speed of continental drift
$1.3\cdot 10^{-9}$	$4.7\cdot 10^{-8}$	Average rate of the Moon receding from the Earth (approx. 38 $[\mathrm{mm}\cdot\mathrm{year}^{-1}]$)
$4.8\cdot 10^{-9}$	$1.7\cdot 10^{-8}$	Human hair growth (approx. 1.24 $[\mathrm{cm}\cdot\mathrm{month}^{-1}]$)
$1.4\cdot 10^{-5}$	$5\cdot 10^{-5}$	Average growth rate of bamboo (approx. 1.2 $[\mathrm{cm}\cdot\mathrm{day}^{-1}]$)
$6\cdot 10^{-4}$	$2.2\cdot 10^{-3}$	Typical speed of Thiovulum majus, the fastest-swimming known bacterium
1-5	3.6-5.4	Average walking human speed
2.39	8.53	World record time 50m freestyle swim
5.78	20.81	World record time marathon
6-7	20-25	Comfortable bicycling speed
10.438	37.578	Average speed of Jamaican athlete Usain Bolt while setting the 100m world record in Berlin on 16 August 12009
30	120	Typical speed of car (freeway)
33.67	121.21	Fastest sail boat Vestas Sailrocket 2
40	140	Typical peak speed of a local service train (or intercity on lower standard tracks)

54	195	Maximum speed an average human can attain during a face-down free-fall in standard conditions
67	240	The top speed of the world's fastest roller coaster, Formula Rossa
90	320	Diving peregrine falcon-fastest bird
91	328	Fastest recorded ball (a golf ball) in sports
113.88	410	Maximum speed of a sport car Bugatti Veyron Super Sport
119.44	430	Maximum speed of a street reglemented motorcycle Suzuki Hayabusa
126-143	452-517	The fastest wind speed ever recorded on Earth, caused by the 11999 Bridge Creek-Moore tornado
167.5	603	Top speed of Japanese L0 Series Maglev train in 12015
250	900	Typical cruising speed of a modern jet airliner, e.g. an Airbus A380
320	$1,200$	The speed of a typical .22 LR bullet
340.3	$1,225$	Speed of sound in standard atmosphere (15 [°C] and 1 [atm])
344.66	$1,240.77$	Max speed reached by the jet-propelled car ThrustSSC in 11997 - Land speed record
373	$1,342.8$	Highest speed recorded during a free fall set by Felix Baumgartner
464	$1,670$	Speed of Earth's rotation at the equator
603	$2,170.8$	Speed of the Concorde airliner
981	$3,532$	SR-71 Blackbird, the fastest aircraft driven by a mechanical jet engine
$1,022$	$3,679$	Average orbital velocity of the Moon around Earth
$1,400$	$5,040$	Speed of the Space Shuttle when the solid rocket boosters separate
$1,500$	$5,400$	Speed of sound in water
$1,789$	$6,443$	Speed of BrahMos II hypersonic cruise missile
$2,000$	$7,200$	Estimated speed of a thermal neutron
$2,375$	$8,550$	Escape velocity from Moon
$3,373$	$12,144$	Speed of the unmanned X-43 rocket/scramjet plane
$7,700$	$27,700$	Speed of International Space Station
$11,107$	$39,985.2$	Speed of Apollo 10 – high speed record for human-crewed vehicle
$11,200$	$40,320$	Average approx. escape velocity from Earth

$17,000$	$61,000$	The approximate speed of the Voyager 1 probe relative to the Sun, when it exited our Solar System
$29,800$	$107,280$	Actual average speed of the Earth in orbit around the Sun
$47,800$	$172,100$	Atmospheric entry speed of the Galileo atmospheric probe inside Jupiter
$192,000$	$690,000$	Top speed of the Parker Solar Probe
$200,000$	$700,000$	Average approx. orbital speed of our Solar System in the Milky Way galaxy
$308,571$	$1,080,000$	Actual approaching velocity of Andromeda Galaxy to our Galaxy
$450,000$	$1,600,000$	Typical speed of a particle of the solar wind, relative to the Sun
$617,700$	$2,224,000$	Escape velocity from the surface of the Sun
$1,610,000$	$5,800,000$	Speed of hypervelocity star PSR B2224+65, which currently seems to be leaving the Milky Way
$14,000,000$	$50,000,000$	Typical speed of a fast neutron
$30,000,000$	$100,000,000$	Typical speed of an electron in a cathode-ray tube
$100,000,000$	$360,000,000$	Typical speed of the return stroke of lightning
$150,000,000$	$540,000,000$	The theoretical escape velocity of a neutron star
$200,000,000$	$720,000,000$	Speed of a signal in an optical fiber
$299,792,455$	$1,079,252,838$	Maximal speed of a proton in LHC accelerator at CERN
$299,792,458$	$1,079,252,848.8$	Speed of light or other electromagnetic radiation in a vacuum or massless particles

Table 9.16: **Some common speed scales**

9.3.3.2.1 Motion parallax

Definition (#9.3.433): "Motion parallax" is a monocular depth cue arising from the relative velocities of objects moving across the retinae of a moving person. The term parallax refers to a change in position. Thus, motion parallax is a change in position caused by the movement of the viewer. Motion parallax arises from the motion of the observer in the environment.

It is perhaps easier to think of what motion parallax is by imagining yourself as a passenger in a car looking out the side window. The car is moving very fast down the highway. The objects very close to the window, such as the small trees planted by the highway, seem to rush by. Beyond the small trees, you can see a distant farmhouse. The farmhouse appears to move more slowly relative to you in the car. You know that the trees and the farmhouse are standing still; you are the object that is moving!

There are some famous videos on Internet highlighting this effect. One such clip of is a moving train with different apparent speeds at the same time has left netizens bamboozled. In this viral clip, a train appears to be moving at very different speeds when looking outside from different windows. In the first scene, the train can be seen moving at a high speed when looking outside from the left window where there is a wall, however, in the next part, the passing visuals on the other side of the window where there is also a wall show the speed of the train to be significantly slower. This is simply due to the fact that the two walls are at very different distance outside from the windows.

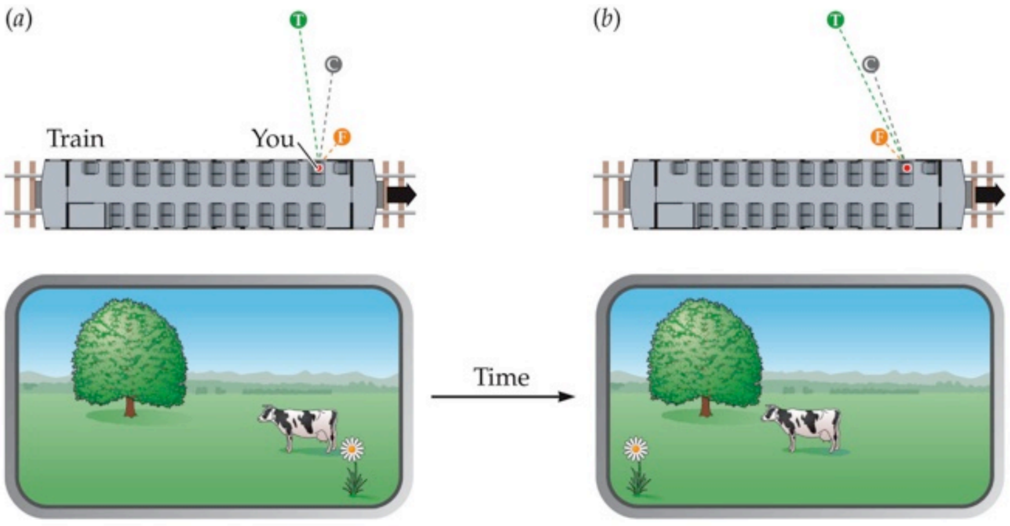


Figure 9.23: **Motion parallax**

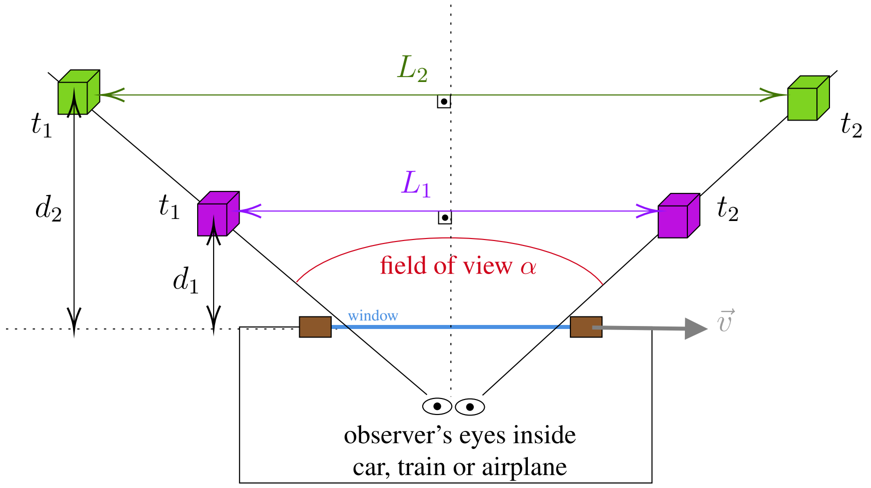
Another famous video is the one of the Professor of psychology at Japan's Ritsumeikan University, Dr. Akiyoshi Kitaoka, who filmed from the front of a train and zoomed in on the tracks ahead. The bizarre clip tricks the brain into thinking the train is travelling slower when the footage is zoomed in.

This is completely a result of vector mathematics and relativity. Normally, velocity is not a scalar quantity! Speed is vectorial. In order to perceive velocity perfectly, the velocity vector must be perpendicular to our viewing angle. That is, the reason why we see a vehicle coming towards us from a distance as if it is moving slower. Because we perceive as speed perfectly only the perpendicular component of the speed vector to our viewing angle. This component is smaller than the absolute speed. As the vehicle approaches, we shift our perspective towards the vehicle. The velocity vector begins to be perpendicular to our field of view. When the vehicle is right next to us, this vector is almost perpendicular to our field of view. But this event is momentary. So normally it is quite difficult for us to predict the absolute velocity. For this reason, when the vehicle is right next to us, we notice a speed close to the actual speed of the vehicle. If we narrow our field of view by zooming the camera, the velocity vector of vehicle entering our field of view will be less perpendicular to our view angle, due to the narrowing of our field of view. For this reason, it will be more difficult to perceive the absolute speed of objects and we will see objects as moving more slowly.

This is one of the reasons why it is not recommended to walk or cross a motorway or railway tracks! Because the perception of speed of vehicles moving parallel to the point of view is highly biased and very likely leads to deadly decisions if not all necessary precautions are taken!

Let us formalize the concept mathematically now! Consider the figure below:



We see that for two different objects being in the same line of sight at time t_1 the distance they need to travel to disappear from the line of sight at time t_2 is obviously not the same as $L_2 > L_1$!

We see that the time while an object is in the field view is obviously given by (we neglect the distance between the observer's eyes and the window):

$$\Delta t_i = \frac{L_i}{v} = \frac{2d_i \tan\left(\dfrac{\alpha}{2}\right)}{v} \tag{9.3.102}$$

So we see that the time motion parallax is directly proportional do the distance from the observer. In other words, if an object is two times further away from a reference object observer it will take twice the time to disappear from the field of view! That's why the further is an object from the observer, the slower it looks like as it takes more time to disappear from the field of view!

9.3.3.3 Acceleration

Definition (#9.3.434): The "scalar acceleration", also known simply "acceleration", denoted "a", is by definition, the variation of the scalar speed during a given amount of time as (we go straight to the limit otherwise we speak of "average linear acceleration"):

$$\boxed{a_i = \frac{\mathrm{d}v_i}{\mathrm{d}t} = \frac{\mathrm{d}^2 x_i}{\mathrm{d}t^2} = \dot{v}} \tag{9.3.103}$$

or in other words: the speed at which the speed change...

The SI unit for acceleration is obviously meter per second squared: $[\mathrm{m}\cdot\mathrm{s}^{-2}]$.

For example, when a car starts from a standstill (zero relative velocity) and travels in a straight line at increasing speeds, it is accelerating in the direction of travel. If the car turns, there is an acceleration toward the new direction. In this example, we can name the forward acceleration of the car a "linear acceleration", which passengers in the car might experience as a force pushing them back into their seats. When changing direction, we might name this "non-linear acceleration", which passengers might experience as a sideways force. If the speed of the car decreases, this is an acceleration in the opposite direction from the direction of the vehicle, sometimes named "deceleration". Passengers may experience deceleration as a force lifting them forwards. Mathematically, there is no separate formula for deceleration: both are changes in velocity. Each of these accelerations (linear, non-linear, deceleration) might be felt by passengers until their velocity (speed and direction) matches that of the car.

Again, if the body is not in uniform motion we have:

$$\vec{a}=\left(\frac{\mathrm{d}v_x}{\mathrm{d}t},\frac{\mathrm{d}v_y}{\mathrm{d}t},\frac{\mathrm{d}v_z}{\mathrm{d}t}\right)=(a_x,a_y,a_z)=(\dot{v}_x,\dot{v}_y,\dot{v}_y) \tag{9.3.104}$$

If the body is in uniform rectilinear motion (we can always generalize to non-rectilinear movement as we will see further below) then we have:

$$\begin{gathered}v_i=\frac{\mathrm{d}x_i}{\mathrm{d}t}\Leftrightarrow v_i\mathrm{d}t=\mathrm{d}x_i\\ \Rightarrow\int\limits_{t_0}^{t}v_i\mathrm{d}t=\int\limits_{t_0}^{t}\mathrm{d}x_i\Rightarrow v_it|_{t_0}^{t}+c_1^{te}=x_i|_{t_0}^{t}+c_2^{te}\\ \Rightarrow x_i(t)-x_i(t_0)=c^{te}+v_it-v_it_0\Rightarrow\Delta x_i=c^{te}+v_i\Delta t\end{gathered} \tag{9.3.105}$$

The constant is to be determined depending on the initial conditions. If the initial position at time zero is zero constant will be zero. If not we write:

$$\boxed{\Delta x_i=x_{i,0}+v_i\Delta t} \tag{9.3.106}$$

which gives us the distance travelled by a body during a given period of time.

If the body is in rectilinear motion and constantly accelerates then we have:

$$\begin{gathered}a_i=\frac{\mathrm{d}v_i}{\mathrm{d}t}\Leftrightarrow a_i\mathrm{d}t=\mathrm{d}v_i\\ \Rightarrow\int\limits_{t_0}^{t}a_i\mathrm{d}t=\int\limits_{t_0}^{t}\mathrm{d}v_i\Rightarrow a_it|_{t_0}^{t}+c_1^{te}=v_i|_{t_0}^{t}+c_2^{te}\\ \Rightarrow v_i(t)-v_i(t_0)=c^{te}+a_it-a_it_0\Rightarrow\Delta v_i=c^{te}+a_i\Delta t\end{gathered} \tag{9.3.107}$$

The constant is to be determined depending on the initial conditions. If the initial velocity at time zero is zero, the constant will be zero. Otherwise we write:

$$\Delta v_i=v_{i,0}+a_i\Delta t \tag{9.3.108}$$

We see this relation more frequently in the form:

$$v_i(t)=v_{i,0}+a_it \tag{9.3.109}$$

or predominantly in the form:

$$\boxed{v=v_0+at} \tag{9.3.110}$$

but we have:

$$v=\frac{\mathrm{d}x}{\mathrm{d}t}=v_0+at\Rightarrow \mathrm{d}x=v_0\mathrm{d}t+at\mathrm{d}t \tag{9.3.111}$$

and if we integrate this relation, we get:

$$\int\limits_{t_0}^{t}\mathrm{d}x=\int\limits_{t_0}^{t}v_0\mathrm{d}t+\int\limits_{t_0}^{t}\mathrm{d}at\mathrm{d}t\Rightarrow \Delta x=x_0+v_0\Delta t+\frac{1}{2}a\Delta t^2 \tag{9.3.112}$$

that we find in the schools most frequently in the form:

$$\boxed{x=x_0+v_0t+\frac{1}{2}at^2} \tag{9.3.113}$$

where the acceleration a can be obviously negative when the object decelerate.

This relation gives the position of a mobile in rectilinear and uniformly accelerated motion (in the majority of physical problems we consider the acceleration as constant). Of the latter, we deduce a large quantity of other useful mathematical relations that are very interesting in physics as well considering ideals cases (frictionless) or real cases. Indeed, rearranging it (elementary algebra), it is possible to obtain acceleration when the time to reach a given speed is known. We can also calculate the distance it takes for a mobile (always in rectilinear movement) with a given acceleration to reach a certain speed.

The first case that we will consider and the best known, is the constant speed acceleration of a falling body in an environment free from any friction (case further treated in our study of tribology).

As we have already proved above, we have when the initial velocity is zero:

$$v=at\Leftrightarrow t=\frac{v}{a}\quad\text{and}\quad x=\frac{1}{2}at^2 \tag{9.3.114}$$

The two combined relations give (according to the tradition of use in schools, we replaced x by h to indicate that the position is often assimilated in practice at a height):

$$x=\frac{1}{2}a\left(\frac{v}{a}\right)^2=\frac{1}{2}\frac{v^2}{a}\Rightarrow v=\sqrt{2ah} \tag{9.3.115}$$

We can take out from this relation the escape velocity of body (useful relation when we will study Astrophysics - see corresponding section - and interesting for comparison when for when we will study General Relativity).

Suppose we already know that two bodies attract each other with an acceleration following classical Newton's model (that we will prove later at page 5255):

$$a=g=\frac{Gm}{R^2} \tag{9.3.116}$$

Placed in the relation $v=\sqrt{2ah}$ of a falling body, we get:

$$v=\sqrt{2\frac{Gm}{R^2}h} \tag{9.3.117}$$

So at the surface of the main attractor body we have the "escape velocity":

$$v_e=\sqrt{\frac{2Gm}{R^2}R}=\sqrt{\frac{2Gm}{R}} \tag{9.3.118}$$

We can answer from this relation, the question of why some solar system planets have atmospheres and others do not (obviously we must take normally into account the molecular agitation ...) as we will discussed ii more in details in the section Astronomy.

What is also interesting in this relation is that we can calculate what should be the radius R of a body of mass m so that to its escape velocity is equal to that of light (referring to Black Holes as we will study them in the section of General Relativity page 5720).

Therefore we have:

$$c=\sqrt{\frac{2Gm}{R}}\Rightarrow R=\frac{2G}{c^2}m \tag{9.3.119}$$

We will see in the section of General Relativity after relatively long calculations in an isotropic gravitational field (Schwarzschild metric) that we will fall back on that relation.

However...! This relation is not directly associated to Black Holes but to a hypothetical "dark star" that is a theoretical object compatible with Newtonian Mechanics that, due to its large mass, has a surface escape velocity that equals or exceeds the speed of light. Whether light is affected by gravity under Newtonian Mechanics is unclear but if it were accelerated the same way as projectiles, any light emitted at the surface of a dark star would be trapped by the star's gravity, rendering it dark, hence the name. Dark stars are only analogous to Black Holes in General Relativity.

Remark

The limits of acceleration that can be perceived by humans were studied by Nesti et al (see [412]) who summarized the results of several experiments. The conclusion is that the lowest acceleration we can perceive is $0.02\,[\mathrm{m\cdot s^{-2}}]$. The variation of acceleration of the Earth on its orbit is as we will prove it in the section of Astronomy (see page 5237) is of the order of $10^{-6}\,[\mathrm{m\cdot s^{-2}}]$ and the variation of acceleration on Earth's due to its rotation when we change of 1° of latitude is of the order of $10^{-4}\,[\mathrm{m\cdot s^{-2}}]$ as we will prove it during our study of centrifugal force later. This explains why the humans cannot detect such small variations. This is why scientists use instruments like accelerometers because as always ... all human senses are very poor to investigate the surrounding world with precision.

Here are some typical acceleration scales (the years are given relatively to the holocene calendar):

Magnitude $[\mathrm{m\cdot s^{-2}}]$	**Magnitude g**	**Description**

$5 \cdot 10^{-14}$	$5 \cdot 10^{-15}g$	Smallest acceleration in a scientific experiment
$1 \cdot 10^{-10}$	$5 \cdot 10^{-11}g$	Typical gravitational acceleration of stars in the Milky Way
$5.93 \cdot 10^{-3}$	$6.04 \cdot 10^{-4}g$	Acceleration of Earth toward the Sun due to Sun's gravitational attraction
1.62	$0.1654g$	Standing on the Moon at its equator
4.3	$0.44g$	Car acceleration 0-100 $[\text{km} \cdot \text{h}^{-1}]$ in 6.4 $[\text{s}]$ with a Saab 9-5 Hirsch
9.80665	$1g$	Standard gravity, the gravity acceleration on Earth at sea level standard
11.2	$1.14g$	Saturn V Moon rocket just after launch
15.2	$1.55g$	Bugatti Veyron from 0 to 100 $[\text{km} \cdot \text{h}^{-1}]$ in 2.4 s
29	$3g$	Space Shuttle, maximum during launch and reentry
29	$3g$	Sustainable for >25 seconds, for an untrained average human
34-39	3.5-$5g$	High-G roller coasters
41	$4.2g$	Top Fuel drag racing world record of 4.4 $[\text{s}]$
49	$5g$	Causes disorientation, dizziness and fainting for most humans (formula One car, maximum under heavy braking)
59	$6g$	Parachutist peak during normal opening of parachute
70.6	$7.19g$	Apollo 16 on reentry
79	$8g$	F-16 aircraft pulling out of dive
88	$9g$	Maximum for a fit, trained person with G-suit to keep consciousness, avoiding G-LOC
88-118	9-$12g$	Typical maximum turn acceleration in an aerobatic plane or fighter jet
147	$15g$	Explosive seat ejection from aircraft
177	$18g$	Physical damage in humans like broken capillaries
209	$21.3g$	Peak acceleration experienced by cosmonauts during the Soyuz 18a abort
333	$34g$	Peak deceleration of the Stardust Sample Return Capsule on reentry to Earth
454	$46.2g$	Maximum acceleration a human has survived on a rocket sled
>491	$>50g$	Death or serious injury likely
982	$100g$	Sprint missile, automobile crash (100 $[\text{km} \cdot \text{h}^{-1}]$ into wall)
$1,540$	$157g$	Peak acceleration of fastest rocket sled run
$2,256$	$230g$	Peak acceleration experience by the Galileo probe during descent into Jupiter's atmosphere

$2,490$	$254g$	Peak deceleration experienced by Jules Bianchi in crash of Marussia MR03, 2014 Japanese Grand Prix
$3,200$	$320g$	A jumping human flea
$3,800$	$380g$	A jumping click beetle
$4,944$	$504g$	Clothes on washing machine, during dry spinning (46 [cm] drum / $1,400$ rpm)
$29,460$	$3,000g$	Baseball struck by bat
$33,000$	$3,400g$	Standard requirement for decelerative crashworthiness in certified flight recorders (such as a Boeing 737 'black box')
$>49,100$	$>5,000g$	Shock capability of mechanical wrist watches
$84,450$	$8,600g$	Current Formula One engines, maximum piston acceleration (up to $10,000g$ before rev limits)
$102,000$	$10,400g$	A mantis shrimp punch
$196,400$	$20,000g$	Spore acceleration of the Pilobolus fungi
$1,000,000$	$100,000g$	Closing jaws of a trap-jaw ant
$1,865,000$	$190,000g$	9×19 [mm] Parabellum handgun bullet, peak

9.3.3.3.1 Osculator Plane

For this subject the reader should first absolutely refer to the section Differential Geometry of the chapter Geometry and especially the part concerning the Frenet frame (see page 2863) that is a prerequisite to understand what will follow.

The vectors speed $\vec{v}$ and acceleration $\vec{a}$ associated with a point P moving form, at every moment t a plane named "osculating plane" of the path (usually curvilinear otherwise the plane is reduced to a straight line in the case of a rectilinear motion).

It is often useful to split the acceleration vector in the osculating plane respectively along the tangent and the normal to the trajectory:

$$\boxed{\vec{a}=\vec{a}_{\text{tg}}+\vec{a}_{\text{n}}} \tag{9.3.120}$$

where the first term of the right part is a vector parallel to the velocity and the second term a vector perpendicular to the velocity and located on the concave side of the path.

Let us express these two vectors explicitly (a more general example is given in the section of Differential Geometry as already mentioned!).

We can write:

$$\vec{v}=\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}=\frac{\mathrm{d}\vec{r}}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}t}=\vec{T}v \tag{9.3.121}$$

where $\mathrm{d}s$ is an element of the curve (curvilinear abscissa) from the path Λ and $\vec{T}$ a unit vector tangent to the path and linked to the point P.

The acceleration is then written:

$$\vec{a}=\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\mathrm{d}(\vec{T}v)}{\mathrm{d}t}=\vec{T}\frac{\mathrm{d}v}{\mathrm{d}t}+v\frac{\mathrm{d}\vec{T}}{\mathrm{d}t} \tag{9.3.122}$$

The first term on the right of the equality is the tangential acceleration and for the second term, even if the speed is constant it appears in the expression of the acceleration to express the change of direction of the speed vector.

Let us decompose the vector $\vec{T}$ in the orthonormal Euclidean base $\mathbb{R}^2$ generated by the family of vector $\vec{i},\vec{j}$:

$$\vec{T}=T_x\vec{i}+T_y\vec{j}=\|\vec{T}\|\cos(\alpha)\vec{i}+\|\vec{T}\|\sin(\alpha)\vec{j}=\cos(\alpha)\vec{i}+\sin(\alpha)\vec{j} \tag{9.3.123}$$

After by derivating in respect to time:

$$\begin{aligned}\frac{\mathrm{d}\vec{T}}{\mathrm{d}t}&=-\sin(\alpha)\frac{\mathrm{d}\alpha}{\mathrm{d}t}\vec{i}+\cos(\alpha)\frac{\mathrm{d}\alpha}{\mathrm{d}t}=(-\sin(\alpha)\vec{i}+\cos(\alpha)\vec{j})\frac{\mathrm{d}\alpha}{\mathrm{d}t}\\&=\left[\cos\left(\alpha+\frac{\pi}{2}\right)\vec{e}_i+\sin\left(\alpha+\frac{\pi}{2}\right)\vec{e}_j\right]\frac{\mathrm{d}\alpha}{\mathrm{d}t}\end{aligned} \tag{9.3.124}$$

By comparing with the initial expression of the vector $\vec{T}$, we see that the terms in brackets above are the components of a new unit vector $\vec{n}$ perpendicular to the vector $\vec{T}$, thus perpendicular to the path and directed toward the center of curvature (see section Differential Geometry page 2863).

Moreover by the definition of the radian (see section Trigonometry page 2503), we have:

$$\frac{\mathrm{d}\alpha}{\mathrm{d}t}=\frac{\mathrm{d}s}{R}\frac{1}{\mathrm{d}t}=\frac{1}{R}\frac{\mathrm{d}s}{\mathrm{d}t}=\frac{v}{R} \tag{9.3.125}$$

where R is the instantaneous (local) radius of curvature of the trajectory.

The expression $\mathrm{d}\vec{T}/\mathrm{d}T$ then becomes:

$$\frac{\mathrm{d}\vec{T}}{\mathrm{d}t}=\frac{v}{R}\vec{n} \tag{9.3.126}$$

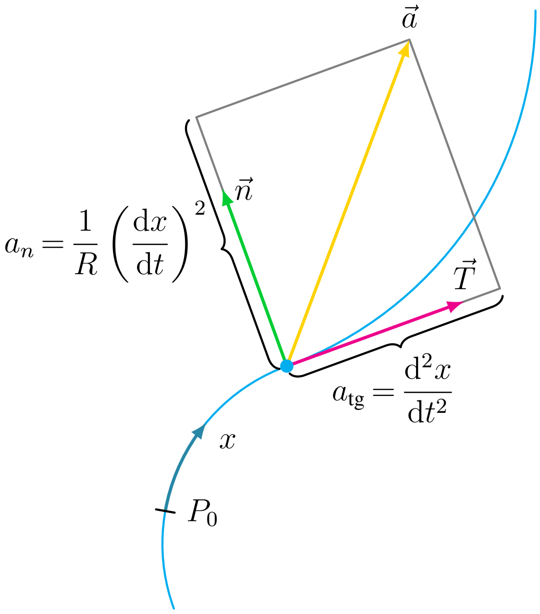
and the second term of the general expression of the acceleration then becomes:

$$v\frac{\mathrm{d}\vec{T}}{\mathrm{d}t}=\frac{v^2}{R}\vec{n} \tag{9.3.127}$$

So we have finally (relation proved with another approach in the section of Differential Geometry):

$$\boxed{\vec{a}=\frac{\mathrm{d}v}{\mathrm{d}t}\vec{T}+\frac{v^2}{R}\vec{n}=\vec{a}_{\text{tg}}+\vec{a}_{\text{n}}} \tag{9.3.128}$$

where once again $\vec{a}_{\text{tg}}$ is the tangential acceleration that express the variation of speed on the trajectory of the body (or point) P and where $\vec{a}_{\text{n}}$ is a term that express the change of direction of the body (point) P without that the latter see its speed change! Commonly the normal acceleration is assimilated, when multiplied by the body (point) mass, to the "centrifugal (fictional) force" (centrifugal meaning: that go away from the center). We will come back more in the details on this force further below.



$\vec{a}$
$\vec{n}$
$a_n=\frac{1}{R}\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2$
$\vec{T}$
$a_{\text{tg}}=\frac{\mathrm{d}^2x}{\mathrm{d}t^2}$
x
P_0

Figure 9.24: Tangential and Normal acceleration

Caution! The centrifugal force is considered in physics as a fictitious force because in fact this is not a force that tends to move the body (particle) away from a center of rotation but it is just that there is a force which is not sufficient (the friction force in the case of carousel or the gravity force in case of planets or satellites) to prevent us from following a straight course by simple inertia. This is why when we are ejected from a carousel we leave tangentially to the rotation and not perpendicularly thereto.

We immediately see that if $\vec{a}_\text{n}=\vec{0}$ the movement can be at least necessarily linear but surely uniform, accelerated or not, while if $\vec{a}_\text{n}\neq\vec{0}$ the trajectory is necessarily curved.

Indeed, as we just say the acceleration is basically rate of change of velocity. In a rotational motion, there are two components of the net acceleration: one Normal(along the radius) and one Tangential (along the circumference). The Normal acceleration serves the purpose of causing the motion to be circular, whereas the tangential one can make the rotation faster or slower. Since a uniform motion itself defines to be a constant velocity motion (i.e. the rotation is going on at a constant speed), the tangential component of acceleration is zero. If the rotation is non-uniform, that means the speed of rotation is changing, thus inevitably leading to the conclusion that the tangential component of the net acceleration is non-zero.

9.3.3.4 Galilean Relativity Principle

Definition (#9.3.435): As far as we know it is impossible for a lively observer in uniform motion to know if he moves relatively to its environment or conversely if the environment is moving relative to him (we can not distinguish the rest and motion at constant speed and direction). Therefore, there can be no absolute reference frame (or privileged reference frame) that can be considered fixed vis-à-vis all other Galileans referential frame which clearly means that all Galilean reference frame must enjoy the same status in Mechanics as they can not be distinguished from each other. This principle is named the "principle of Galilean relativity" or "Galilean invariance".

Specifically, the term "Galilean invariance" today usually refers to this principle as applied to Newtonian Mechanics, that is, Newton's laws hold in all frames related to one another by a Galilean transformation. In other words, all frames related to one another by such a transformation is inertial (meaning, Newton's equation of motion is valid in this frame). In this context it is sometimes named "Newtonian relativity".

So for example, the two observers depicted below, the one on the ground in the reference frame S and the one in unform motion in a vehicle in the reference frame S' will observe exactly the same trajectory of the ball they throw from their point of view and will conclude to the same laws of physics (!):

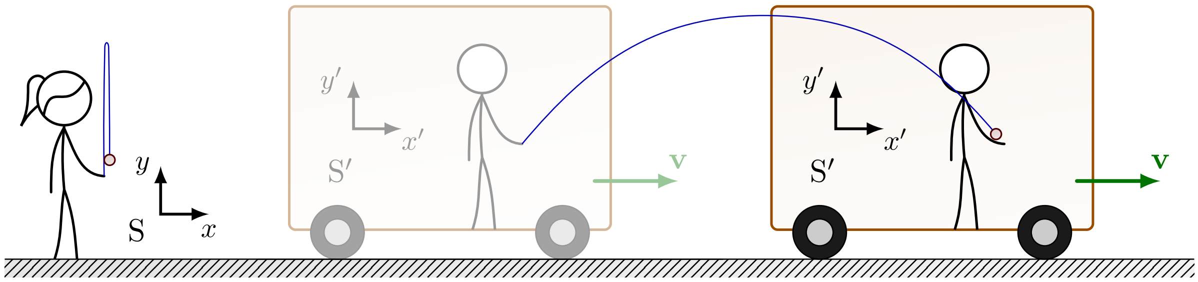


Figure 9.25: **The principle of Galilean relativity illustrated (author: Izaak Neutelings)**

Hence uniform motion (constant velocity) in a vacuum is undetectable! This is a core principle of relativity, stating that no physical measurement can distinguish between inertial frames of reference in uniform motion.

This principle (not to be confused with the principle of Special Relativity because the assumptions differ a little bit ...) follows directly from the study of what we name the "Galilean transformation" that we will study below for Kinematics and for which we will give a more in-deep example in the section of Special Relativity with the Galilean Transformation of a wave equation.

Definition (#9.3.436): A "Galilean transformation" is a sequence of mathematical operations on a physical law that determines the properties of one or more "observable" (speed, strength, momentum, etc.) when we move during the study of a physical phenomenon from one repository to another repository: one supposed to rest (relatively to the second), and the other in uniform motion (or vice versa).

The question at the historical origin was to answer if it was more legitimate to study a phenomenon in a repository or another one. More exactly, we want to determine whether the form of physical laws keep the same algebraic form regardless of the repository in which we study them.

Let us have a more closer look at this:

Given two repositories in movement relative to each other at a constant speed $\vec{u}(u_x, u_y, u_z)$. For a given Cartesian reference frame $(\vec{x}, \vec{y}, \vec{z})$ at rest (or supposed such) we will put for the second repository $(\vec{x}', \vec{y}', \vec{z}')$ so that it is aligned with the x-axis of the first repository to simplify calculations with $\vec{u}(u_x, 0, 0)$:

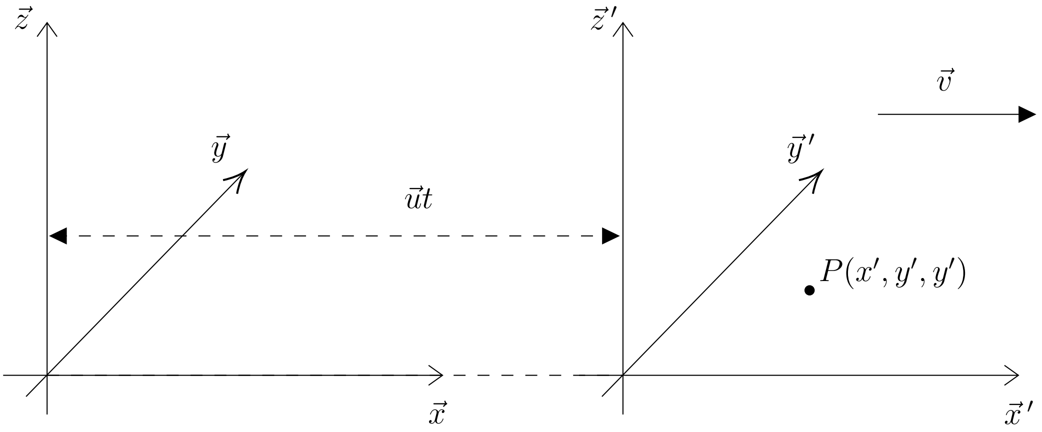

Figure 9.26: **Example repositories in uniform relative motion with respect to each other**

We will also put in the second frame of reference, a material point P of coordinates $\vec{P}(x',y',z')$.

Remark

We assume known the concept of "linear momentum" p defined further below rigorously. Let us just recall here that the linear momentum of the animated point P of mass m', with a speed v (norm) in $(\vec{x}',\vec{y}',\vec{z}')$ is given by:

$$p' = m'v' \tag{9.3.129}$$

We then have by applying the conventional relations of rectilinear kinematics:

$$x' = x - u_x t \qquad y' = y \qquad z' = z \tag{9.3.130}$$

$$t' = t \qquad m' = m \tag{9.3.131}$$

Remark

Note that the last equation expresses the assumption of a universal time and mass independent of the relative motion of different observers. This has to be compared with our future study of Special Relativity (see the section with the corresponding name page 5627).

We get:

$$\begin{aligned} p'_x &= mv'_x = m\frac{\mathrm{d}x'}{\mathrm{d}t'} = m\frac{\mathrm{d}(x-u_x t)}{\mathrm{d}t} = m\left(\frac{\mathrm{d}x}{\mathrm{d}t} - \frac{\mathrm{d}u_x}{\mathrm{d}t}t - \frac{\mathrm{d}t}{\mathrm{d}t}u_x\right) = m\left(\frac{\mathrm{d}x}{\mathrm{d}t} - 0\cdot t - 1\cdot u_x\right) \\ &= m\left(\frac{\mathrm{d}x}{\mathrm{d}t} - u_x\right) = m(v_x - u_x) \end{aligned} \tag{9.3.132}$$

hence $v'_v = v_x - u_x$ and therefore we get for the force (we will study further below what links linear momentum and force together):

$$F_x = \frac{\mathrm{d}p_x}{\mathrm{d}t} = \frac{\mathrm{d}m(v_x-u)}{\mathrm{d}t} = 0 = F'_x = \frac{\mathrm{d}p'_x}{\mathrm{d}t'} = 0 \tag{9.3.133}$$

The result is interesting since Newton's second law keeps exactly the same shape and the same value in the two repositories (we better understand the name of "Newton relativity"). The fact that we were moving or not has therefore no impact on our vision of the world that remains exactly the same (in this model because when we will study Special Relativity we will see that this is not satisfied anymore!!!).

Consequence: Since the forces are the same, no mechanical experience can determine whether a Galilean is the absolute coordinate system (i.e. two observers in two different Galilean frames, cannot with mechanical experience determine which moves relative to the other one).

So in Classical Mechanics, there is no absolute Galilean reference frame!

Notice, however, that this is achieved by assuming that:

$$\frac{\mathrm{d}mu}{\mathrm{d}t}=\frac{\mathrm{d}mv_x}{\mathrm{d}t}=\frac{\mathrm{d}mv'_x}{\mathrm{d}t'}=0 \tag{9.3.134}$$

that is to say, we require that the relative velocity is uniform (constant), the mass is also constant and especially that $t=t'$.

But in fact, this transformation is fundamentally wrong as discussed in more detail in our study of Special Relativity (see the section with the corresponding name page 5627). Indeed, the easiest way to see it that is more experimental than theoretical (we keep the theoretical one for the section of Special Relativity) is to consider an object moving along the axis with a speed v measured in the apostrophed reference frame:

$$x'=vt' \tag{9.3.135}$$

then what will be its velocity w in the apostrophed reference frame? If the Galilean transformation is fundamentally true, it would be enough to replace in the above relation x' and t' by their expressions in function of t:

$$x-ut=vt \qquad \text{or} \qquad x=(u+v)t \tag{9.3.136}$$

thus (velocity addition law):

$$w=\frac{\mathrm{d}x}{\mathrm{d}t}=u+v \tag{9.3.137}$$

But there was a problem ... an experiment involving light rays (electromagnetic waves) was conducted at the beginning of the 120th century (holocene calendar), and showed that this addition law was false. This experiment named "Michelson-Morley experiment" (see [390]) and later the "de Sitter double star experiment" (see [133]) changed forever our vision of the world ... and brought Albert Einstein to develop the theory of Special Relativity by requiring that the speed of light to be constant regardless of the movement of the reference frame (see section Special Relativity page 5627):

$$\boxed{c:=v_{\text{light}}=c^{te}} \tag{9.3.138}$$

If we measure the speed and other vector quantities, we find that the results of measurements of the components x', y', z', t' are not identical to those obtained on x, y, z, t. In physics, the "principle of covariance" emphasizes the formulation of physical laws using only certain physical quantities such that their measurements in different frames of reference can be unambiguously correlated. Mathematically, the physical quantities must transform "covariantly", that is, under a certain representation of the group of coordinate transformations between admissible frames of reference of the physical theory. The corresponding group is the referred to as the "covariance group". The covariance principle states that the laws of physics should transform from one frame to another covariantly, that is, according to a representation of the covariance group (Lorentz matrices in Special Relativity and in General Relativity the covariance group consists of all arbitrary invertible and differentiable coordinate transformations).

As we know, laws (formulas) are relations between observable (terms), relations deduced from many observations. The research of laws is governed by what we might name the "principle of simplicity": laws in the smallest possible number, expression the simple as possible between terms and in minimum quantity. But the characteristic of a good law is also the covariance during a change of reference frame. The Physics (in the sense of the theory that describes the sensitive reality) will no longer be linked to the observer nor his associated Galilean space-time.

However, let us give an important counterexample in Classical Mechanics: the force between two stationary electric charges in a referential frame use in this reference frame only electrostatic theory. If the same system is observed from a moving reference frame relative to the first, it will have to be described by the electromagnetism theory (as we will see in the section of Electrodynamics an electric charge in movement produces a magnetic field). This can be explained only thanks to the covariance group of Special Relativity[14].

By construction Classical Mechanics is being covariant by Galilean transformation (change of Galilean reference frame): the dynamic postulate (force) takes the same form in the different Galilean frames as we have just seen!

---

[14] See our study of the Joules-Bernoulli equations in the section of Special Relativity at page 5696

9.3.4 Angular Momentum

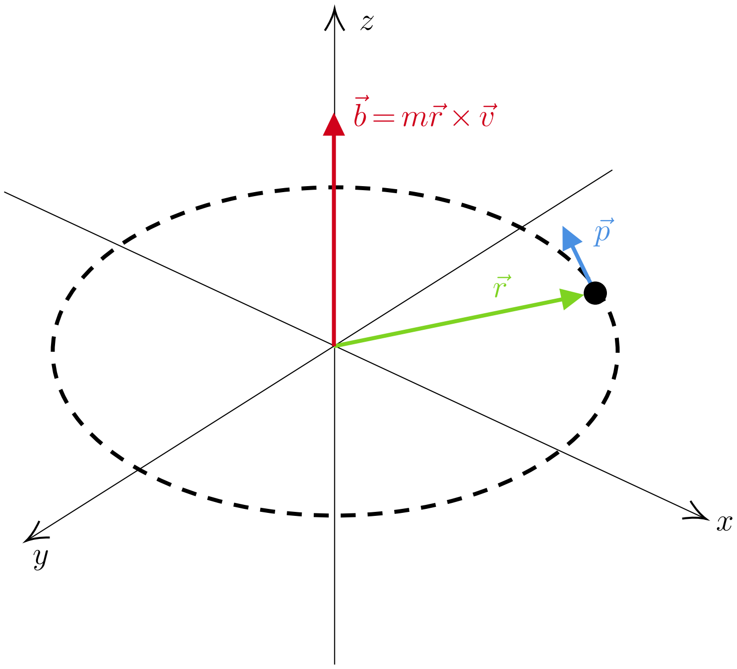
Definition (#9.3.437): The "angular momentum" (rarely "moment of momentum" or "rotational momentum" or commonly named "orbital angular momentum" in astronomy) $\vec{b}$ with respect to a point O of a particle of mass m moving at the speed $\vec{v}$ on $\vec{r}$ is defined by:

$$\boxed{\vec{b}=\vec{r}\times\vec{p}} \tag{9.3.139}$$

with $\vec{p}$ being the linear momentum (see definition during the Newton's second law statement) given by:

$$\vec{p}=m\vec{v} \tag{9.3.140}$$

By definition, the angular momentum is a vector perpendicular to the plane containing the vectors $\vec{r}$ and $\vec{p}$ and if the particle moves in a plane, the direction of $\vec{b}$ is constant but not necessarily in the same direction depending or the rotating sense of the particle.



A special but important case in Astronomy and Mechanics is to calculate the angular momentum of a circular plane motion of radius r. In this situation, the "radius vector" $\vec{r}$ is then always perpendicular to the direction of the velocity vector $\vec{v}$ and therefore:

$$\boxed{\vec{b}=m\vec{r}\times\vec{v}\Rightarrow\|\vec{b}\|=mvr=m\omega r^2\Rightarrow mr^2\vec{\omega}} \tag{9.3.141}$$

We see here appear the definition of the "rotation vector $\vec{\omega}$" also sometimes denoted by $\vec{\Omega}$.

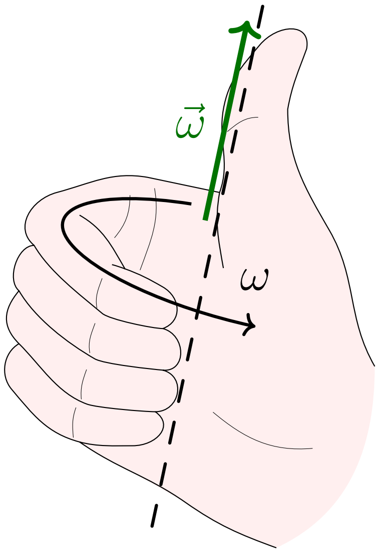


Figure 9.27: **Angular momentum right-handed rule (author: Izaak Neutelings)**

For a non rectilinear motion path (a conical for example), we introduce the normal and tangential velocity components (we will in-deep this further below):

$$\vec{v}=\vec{v}_n+\vec{v}_{\text{tg}} \tag{9.3.142}$$

But as the velocity is the change in position over time the velocity is (by definition) tangent to the curve. So we get:

$$\vec{b}=m\vec{r}\times(\vec{v}_n+\vec{v}_{\text{tg}})=m\vec{r}\times\vec{v}_{\text{tg}} \tag{9.3.143}$$

If we take a differentiable vector function $\vec{v}(t)$ (a velocity vector). If its speed is such that $\vec{v}(t)=c^{te}$ then at any point which $\mathrm{d}\vec{v}/\mathrm{d}t$ is non zero, $\mathrm{d}\vec{v}/\mathrm{d}t$ is perpendicular to $\vec{v}(t)$.

The shortest way to prove this assertion is to remember that:

$$\|\vec{v}\|^2=v^2=\vec{v}\circ\vec{v} \tag{9.3.144}$$

After differentiating:

$$2v\frac{\mathrm{d}v}{\mathrm{d}t}=\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}\circ\vec{v}+\vec{v}\circ\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=2\vec{v}\circ\frac{\mathrm{d}\vec{v}}{\mathrm{d}t} \tag{9.3.145}$$

and since its speed is constant:

$$2v\cdot 0=2\vec{v}\circ\frac{\mathrm{d}\vec{v}}{\mathrm{d}t} \tag{9.3.146}$$

Since $\vec{v}\neq 0$ and $\mathrm{d}\vec{v}/\mathrm{d}t\neq 0$ then they have to be perpendicular!

So, coming back to:

$$\vec{b}=\vec{r}\times\vec{v}_{\text{tg}} \tag{9.3.147}$$

in scalar form this gives:

$$b=mrv_{\text{tg}}=mr^2\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{9.3.148}$$

where r is therefore named the "radius of curvature" of the trajectory as we already know (see section Differential Geometry page 2865).

Let us now study the derivative of the angular momentum:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\frac{\mathrm{d}(\vec{r}\times\vec{p})}{\mathrm{d}t}=\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\times\vec{p}+\vec{r}\times\frac{\mathrm{d}\vec{p}}{\mathrm{d}t} \tag{9.3.149}$$

In the right-hand side, we have by the definition of the vector product:

$$\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}\times\vec{p}=\vec{v}\times m\vec{v}=\vec{0} \tag{9.3.150}$$

and also:

$$\vec{r}\times\frac{\mathrm{d}\vec{p}}{\mathrm{d}t}=\vec{r}\times\vec{F}=\vec{M} \tag{9.3.151}$$

Which gives finally:

$$\boxed{\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\vec{r}\times\vec{R}=\vec{M}} \tag{9.3.152}$$

The derivative with respect to time of the angular momentum of a moving point is equal to what we define as the "moment of force $\vec{M}$" which will also be discussed further below and whose units are that of energy and is a vector perpendicular to the plane defined by $\vec{r}$ and by $\vec{F}$ (by construction of the cross product as seen in the section of Vector Calculus!).

Remark

This latter relation makes that we sometimes name the angular momentum as "moment of linear momentum"...

What is highly impressive in this result (instantaneous change of angular momentum), is that any body having a non-zero angular momentum and subject to no moment of force, maintains the direction and norm of $\vec{b}$ in space and time.

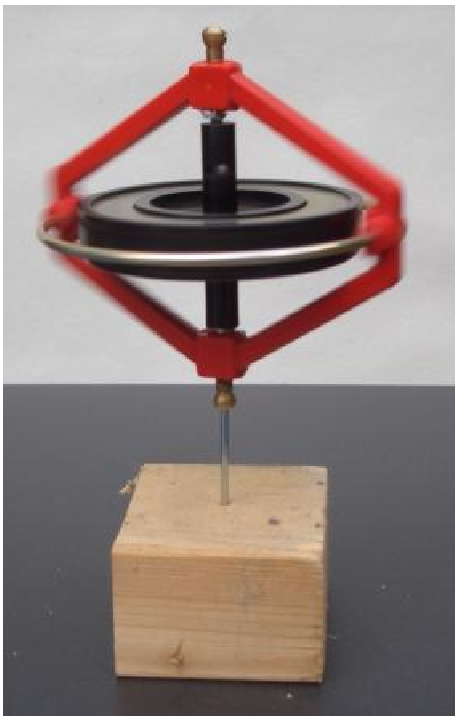

Figure 9.28: Gyroscope remaining upright while spinning owing to the conservation of its angular momentum (source: Wikipedia)

This result will allow us to study the dynamic of the gyroscope and all other bodies having similar properties (such as the Earth rotating on itself and that points approximately to the North Star, i.e. Polaris nowadays, which is a major cause of origin of the seasons!). We will study further below the gyroscope and its properties, because their behaviour is fascinating and the theoretical results arising find applications in astrophysics, atomic physics and even in philosophy. Indeed, the conservation of the orientation of the angular momentum vector leads to the conclusion that even if the space was completely empty of its contents in the whole Universe and contained an object with an angular momentum, the empty space has however a property which allows the object in question where it oriented it angular momentum... which is quite disturbing! So the empty space is not nothing otherwise relatively to what turns the object into space? It rotates relative to the space itself!

We also have:

$$\vec{b}=\int_{t_1}^{t_2}\vec{M}\mathrm{d}t \qquad (9.3.153)$$

where the integral is named "angular impulsion" and the previous relation sometimes is named "theorem of angular momentum" (we'll see a generalization of this theorem in the proof of König's theorem later). It is stated as following: The angular impulsion provided by a moment of force between the moments t_1 and t_2 is equal to the variation of the angular momentum during this time interval.

In the study of solid dynamic this theorem plays a fundamental role, similar to the dynamic Newton equation $\vec{F}=m\vec{a}$.

The use of angular momentum makes it easy to prove the Kepler law of areas (Kepler's second law), which plays an important role in the understanding of planetary motion (see section

Astronomy page 5233) or to prove that in an isolated Earth-Moon system, the total angular momentum is conserved, so if the Earth slows its rotation and the Moon keep it constant, it forces the Moon to increase its distance from Earth!!!

Let us see this last statement:

Imagine a particle moving under the action of a force $\vec{F}$ constant and parallel to $\vec{r}$. We say that this force is a "central force" if its direction constantly goes through the same fixed point, named the "center of force". The magnitude of the force only depends on the distance r of the object from the origin and is directed along the line joining them (in the case of a force field):

$$\boxed{\vec{F}=\vec{F}(\vec{r})=F(\|\vec{r}\|)\vec{r}} \tag{9.3.154}$$

Therefore:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\vec{r}\times\vec{R}=\vec{0} \tag{9.3.155}$$

as in central force problems $\vec{F}$ is parallel to $\vec{r}$.

Therefore the angular momentum relative to the center of force is constant if the force is central! The converse is also true: if the angular momentum is constant, its derivative with respect to time is zero and the direction of the force is always collinear to $\vec{r}$ so the force is central.

For example, in the motion of a planet around the Sun (actually a G2V-type star, aka yellow dwarf) or an electron around the nucleus of the atom (in the Bohr model...) the momentum of this force relatively to the center because is obviously zero as no outside element acts on the system, that is to say based on the figure below:

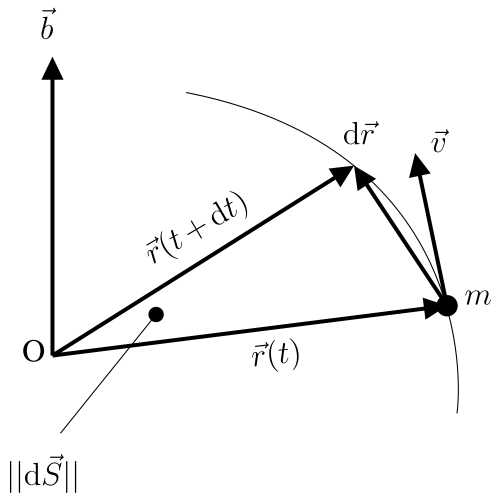

Figure 9.29: **Illustration of momentum**

Then we have:

$$\vec{M}=\vec{r}\times\vec{F}=\vec{0}\Leftrightarrow\vec{M}=\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\vec{0} \tag{9.3.156}$$

Therefore:

$$\vec{b}=\vec{r}\times m\vec{v}=\vec{c}^{te} \tag{9.3.157}$$

On the other hand, the element surface $\mathrm{d}\vec{S}$ described by the motion of the radius $\vec{r}$ is (according to the figure above and the properties of the vector product): therefore:

$$\dfrac{\mathrm{d}\vec{S}}{\mathrm{d}t}=\dfrac{1}{2}\left(\vec{r}\times\dfrac{\mathrm{d}\vec{r}}{\mathrm{d}t}\right)=\dfrac{1}{2}(\vec{r}\times\vec{v}) \tag{9.3.158}$$

Using the relation $\vec{b}=\vec{r}\times m\vec{v}=\vec{c}^{te}$ we get:

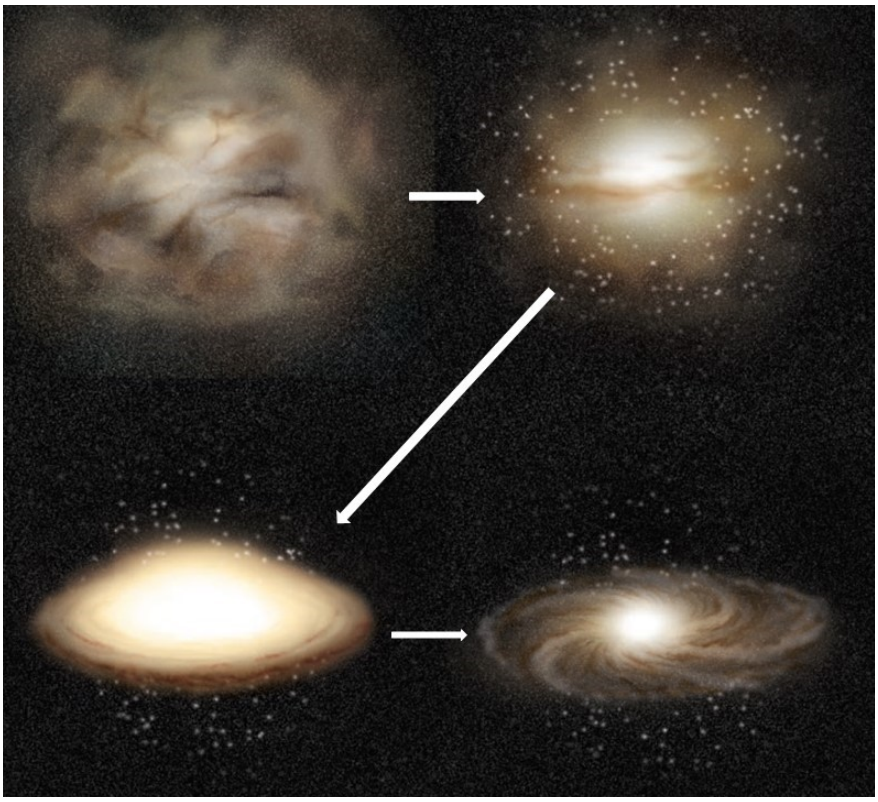
$$\boxed{\dfrac{\mathrm{d}\vec{S}}{\mathrm{d}t}=\dfrac{1}{2m}(\vec{r}\times m\vec{v})=\vec{c}^{te}} \tag{9.3.159}$$

Consequences:

1. The areal velocity is constant in a central force problem, that is to say that the areas scanned in equal times are equal. It is the Kepler areas law (see section Astronomy page 5234)!
2. The plane $\vec{r},\vec{v}$ is fixed because $\vec{r}\times m\vec{v}=\vec{c}^{te}$. Thus the trajectory of a planet in a ideal case is viewed as moving in a plane relatively to the reference frame of the force center.

We'll obviously come back on this relation in the section Astronomy to write it in a slightly more traditional form.

We (almost) all know that the Earth, the other planets and their moons all revolve around the Sun in elliptical orbits (from the point of view of the Sun referential otherwise the trajectory is helicoidal...!). However, have you ever stopped to wonder why these celestial objects move around the Sun in such a way that our Solar System appears to be lying on a plane, rather than going every which way and the same observation can also be done for Saturn's rings, galaxies or Black Holes disk accretion?



We can trace the origin of our Solar System to a massive shapeless 'blob' of matter floating through space about 4.6 billion years ago (see [69]).

The particles in this blob gradually began to move closer due to gravity, and whenever there are multiple particles and powerful gravitational forces, there are also collisions and therefore heating and emissions of radiations outside of the cloud. These collisions and the subsequent trajectories of these particles are obviously random, making them almost impossible to predict. Although these objects move randomly, the one thing that remains constant as we just saw is the angular Momentum as the latter does not irradiate anything outside the cloud and to be changed must be influence by an external force!!! The solar system is an isolated system in itself (in first approximation!). The galaxy is also an isolated system (in first approximation), since the gravitational effect of other cosmic objects is negligible.

So an isolated system and therefore without interaction with external objects, the total Angular Momentum has to be conserved!

Remark

A common question is: what is the origin of angular momentum in the early time of our universe? First a thing to know is that for the same reason energy and momentum is not conserved in an expanding universe (violation of space translation), conservation of angular momentum (result of rotation invariance) is also not conserved in curved space-time unless the metric has rotational symmetry. And keep in mind the spin of an object can be compensated by an opposite change in spin in one or more other objects (as angular momentum is a vectorial quantity).

This physical quantity is constant around a fixed axis. This axis is a point in 2-dimensional space, and in our world, which exists in 3 dimensions, this axis turns out to be a line. The system rotates along a plane that is perpendicular to the axis. Therefore, whenever particles collide, they may move in any direction, but all the up and down motion cancels out, always following the rule that the total spin in that plane must be constant. Over time and after countless collisions, these particles lose their freedom in everything except 2-dimensional space, thereby aligning themselves in a plane.

9.3.4.1 Moments

A "moment" (not to be confused with Momentum!) or "torque" is an expression involving the product of a distance and a physical quantity, and in this way they account for how the physical quantity is located or arranged. Moments are usually defined with respect to a fixed reference point; they deal with physical quantities as measured at some distance from that reference point. For example, the moment of force acting on an object, often named "torque", is the product of the force and the distance from a reference point. In principle, any physical quantity can be multiplied by distance to produce a moment; commonly used quantities include forces, masses, and electric charge distributions.

OK let's go! In fact we have seen just above that the "moment of force" was defined by (temporal variation of the angular momentum):

$$\boxed{\vec{M}=\vec{r}\times\vec{F}} \tag{9.3.160}$$

where $\vec{M}$ is the moment (or "torque" also denoted sometimes by the letter τ) of the force $\vec{F}$ relatively to the origin of the vector $\vec{r}$. It is important to note that the force momentum has for units "energy" ([J]) and is also perpendicular to $\vec{r}$ and $\vec{F}$ by construction!

It must be also notice that increasing the radius of force application thereby giving the opportunity to decrease the force necessary to keep a constant force momentum in a mechanical system certainly reduces the effort (force) but in the end not the energy expended since the traveled distance is bigger.

If we express the norm of the force moment $\vec{M}$, by the definition of the cross product, we get:

$$\|\vec{M}\|=\|\vec{F}\|\cdot\|\vec{r}\|\sin(\alpha)=\|\vec{F}\|b \tag{9.3.161}$$

Therefore appears a quantity:

$$b=\|\vec{r}\|\sin(\alpha) \tag{9.3.162}$$

which by definition is the "lever arm" of the force $\vec{F}$ and whose location is given by the axis of rotation of the body due to the resulting moment of force (do not confuse this with the notation $\vec{b}$ of the angular momentum!).

Warning! The principle of the lever arm is thus a great force multiplier but in no case it multiplies the work (energy)!

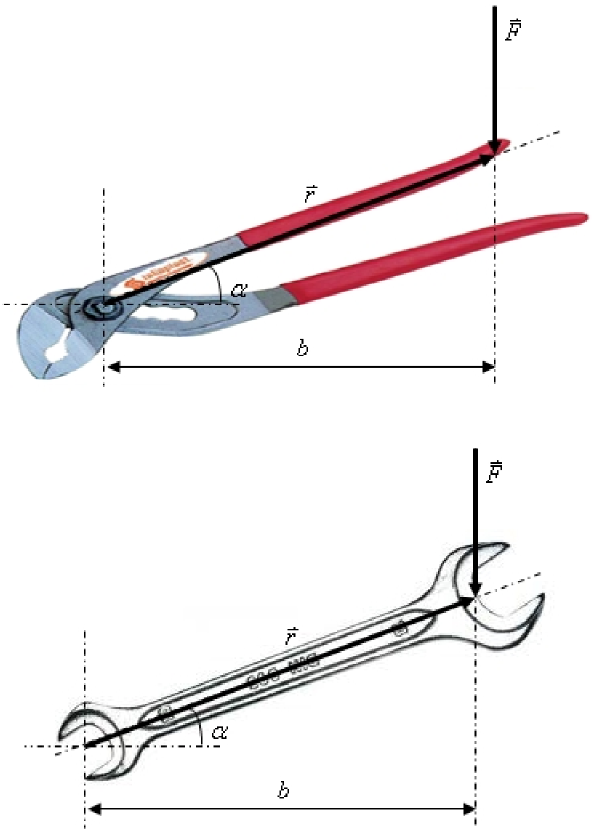


Figure 9.30: **Example of some everyday lever arm**

Remark

The case of application of changes of winter/summer of tourism cars is well known by motorists as it is recommended by most manufacturers to apply a torque of 120 [Nm] for the tightening of the bolts.

For an extended body, subject to forces $\vec{F}_1, \vec{F}_2, \ldots, \vec{F}_n$ to be in total equilibrium, it is not only necessary that the resultant of these forces is zero (no translation) but also the resulting force moments is zero too (no rotation). That is to say:

$$\sum_{i=1}^{n} \vec{F}_i = \vec{0} \quad \text{and} \quad \sum_{i=1}^{n} \vec{M}_i = \vec{0} \tag{9.3.163}$$

Thus more explicitly:

$$\boxed{\begin{aligned} &\sum_{i=1}^{n} F_{i,x} = \sum_{i=1}^{n} F_i \cos(\alpha_i) = 0 \\ &\sum_{i=1}^{n} F_{i,y} = \sum_{i=1}^{n} F_i \sin(\alpha_i) = 0 \\ &\sum_{i=1}^{n} M_i = \sum_{i=1}^{n} (x_i F_{i,y} - y_i F_{i,x}) = \sum_{i=1}^{n} F_i (x_i \sin(\alpha_i) - y_i \cos(\alpha_i)) = 0 \end{aligned}} \tag{9.3.164}$$

When the components of a system that meets the two above relations are known, then we speak of sometimes of "isostatic system".

By definition, a "couple of force" or simply "couple" is defined as a set of two forces of equal magnitude but opposite direction, acting along two parallel lines on the same extended body. The resultant of course no forces indicates that the couple produces no translation effect. But the sum of the moments is not zero, the body undergoes a rotation such that:

$$\vec{M}=\vec{r}_1\times\vec{F}_1+\vec{r}_2\times\vec{F}_2=\vec{r}_1\times\vec{F}_1-\vec{r}_2\times\vec{F}_1=(\vec{r}_1-\vec{r}_2)\times\vec{F}_1=\vec{b}\times\vec{F} \tag{9.3.165}$$

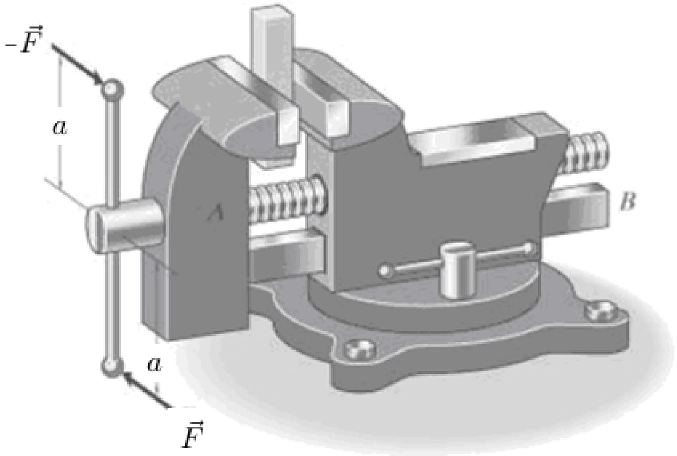

Figure 9.31: **Example of couple of force**

To avoid any confusion here is a small refresh:

- A Moment is equivalent to a force multiplied by the length of the line passing through the point of reaction and that is perpendicular to the force.
- Torque is a moment that is applied in such a way that it tends to rotate a body around its axis. The usual example being a torsional moment on a shaft.
- A Couple is the moment that is the resultant of two forces of the same magnitude, acting in opposite direction at the same distance from the reaction point. Therefore, this force system is statically equivalent to a pure moment (no resultant force).

Let us also mention the composition of force moments with the following ultra-classic case of balanced moment:

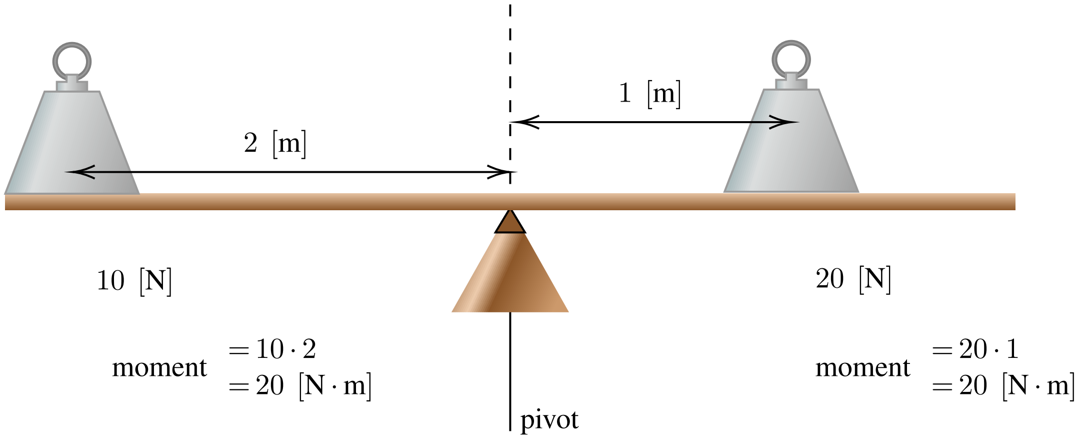

Figure 9.32: **Balanced moment example**

And also the analysis of the typical well known situation involving two moments of force:

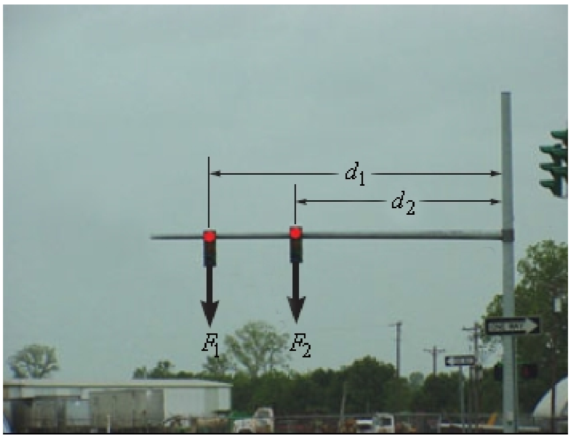

Figure 9.33: **Composition of force moments**

for which it is quite obvious that the force of the resulting moment of force has magnitude the sum of the two elementary forces:

$$F_R = F_1 + F_2 \tag{9.3.166}$$

To calculate the corresponding resultant distance, we will use the theorem of the center of mass, which as we have prove above and in the section of Euclidean Geometry is given in the general case by:

$$\overrightarrow{OG} = \frac{\sum\limits_{i=1}^{n} \alpha \overrightarrow{OA_i}}{\sum\limits_{i=1}^{n} \alpha_i} \tag{9.3.167}$$

and that in the present case is reduced to:

$$d = \frac{\sum\limits_{i=1}^{n} F_i d_i}{\sum\limits_{i=1}^{n} F_i} = \frac{F_1 d_1 + F_2 d_2}{F_1 + F_2} \tag{9.3.168}$$

We thus have the resulting final moment which is:

$$M_R = F_r d = (F_1+F_2)\frac{F_1 d_1 + F_2 d_2}{F_1+F_2} = F_1 d_1 + F_2 d_2 = M_1 + M_2 \tag{9.3.169}$$

Thus, the resultant moment of force is the simple sum of the elementary moment of forces of forces.

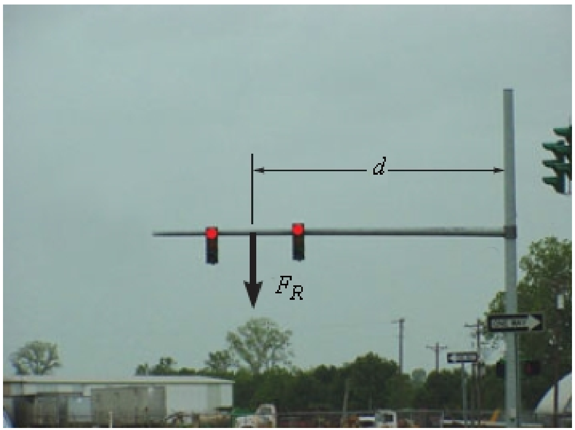

Figure 9.34: **Resulting composition of force moments**

Now that we have quite properly defined what was a force and moment of force, we can immediately begin the study of static forces:

9.3.5 Static Forces

The study field of static forces is a quite difficulty domain to generalize when the target students discover the concept of forces and momentum. Most books use many examples (like pulley systems, levers, balances, friction, truss, etc.) to get the reader to assimilate the method of analysis needed to resolve problems in this field of Classical Mechanics. Far from being against this method, we do not want to restrict ourselves or dwell (following viewpoints) to specific examples, but we have preferred to propose a method of analysis that would work without fail in any case.

Definitions (#9.3.438):

D1. The "static forces" is the field of physics that studies the effect of the resulting forces (or moments of force) that are constant over time, applied on a punctual or extended body.

D2. When the sum of all vector forces and moments of force is zero, there is no movement for a body initially not moving. We then speak of "static equilibrium" (but the forces still exist within the system) such that the forces and moments of forces cancel each other:

$$\sum_{i=1}^{n} \vec{F}_i = \vec{0} \quad \text{or} \quad \sum_{i=1}^{n} \vec{M}_i = \vec{0} \tag{9.3.170}$$

More generally an object is in equilibrium if the linear momentum of its center of mass is constant and if its angular momentum about its center of mass is constant.

Remark

The previous relations show us that it is not because a system is in static equilibrium that is not subject to any force (the vector sum of forces can cancel but the forces are non-zero)!

We have then the following corollaries:

C1. When analysing a static forces system, we must always (!!!) work with vector components of forces and moments of forces (by the first Newton's law!).

C2. We must therefore impose a reference frame in which all forces components will be expressed:

- In the case of punctual body (particle point) on which forces are applied, we must assimilate the origin of the coordinate to the position of that point.
- If the extension lines of all forces applied on an extended body are all converging at a given point, the system can be considered as an isolated body reduced at this point of convergence.
- If the extended body is plunged into an isotropic, coplanar and constant over time field of forces (gravitational, electrostatic, magnetic ...) then all applied forces can be reported to the center of gravity.

Proof 9.4.2. We have seen during our study of the section of Vector Calculus that the sum of vectors of a same set, put extremity by extremity (at the pictorial representation level) or algebraically added constitute what we name the "resultant" of the system of forces or momentum forces (torques):

$$\vec{R}_{\vec{F}}=\sum_{i=1} n\vec{F}_i \quad \text{and/or} \quad \vec{R}_{\vec{M}}=\sum_{i=1}^{n}\vec{M}_i \tag{9.3.171}$$

It is clear that a material point is therefore defined in a static state if the resultant of the competing forces is equal to zero. Thus, a punctual body is at rest (constant speed equal to zero) if the quantity $\vec{R}_{\vec{F}}$ is zero.

This condition is however not sufficient for an extended body (non-punctual): the latter can not move (no translation movement), but can turn on itself by the application forces outside its barycenter (the forces are then momentum forces- torques - acting on points of the body in question).

Now let us imagine a set of forces $\vec{F}_i$, each of them applied at a point of position-vector $\vec{r}_i$ of an extended mobile and all parallel to a given common direction, indicated by a unit vector $\vec{u}$. The resultant of these forces is then:

$$\vec{R}_{\vec{F}}=\sum_{i=1}^{n}\vec{F}_i=\sum_{i=1}^{n}F_i\vec{u}=\left(\sum_{i=1}^{n}F_i\right)\vec{u} \tag{9.3.172}$$

The resulting norm is then obviously:

$$\|\vec{R}_{\vec{F}}\|=\sum_{i=1}^{n}F_i \tag{9.3.173}$$

Similarly, the vector sum of the parallel corresponding moment of forces (torques) are written:

$$\vec{R}_{\vec{M}}=\sum_{i=1}^{n}\vec{r}_i\times\vec{F}_i=\sum_{i=1}^{n}\vec{r}_i\times(F_i\vec{u})=\left(\sum_{i=1}^{n}\vec{r}_iF_i\right)\times\vec{u} \tag{9.3.174}$$

Let us now search the vector position $\vec{r}_C$ of a fictive point C, named the "center of force" such as the moment of the resultant $\vec{R}_{\vec{F}}$ applied at point C is equal to the total torque $\vec{R}_{\vec{M}}$. In other words, $\vec{r}_C$ must be the solution of the vector equation:

$$\vec{R}_{\vec{M}}=\vec{r}_C\times\vec{R}_{\vec{F}} \tag{9.3.175}$$

If it is possible to find such a point C, so we do not longer need, in principle, to calculate the individual force momentum of each force and make the vector sum. Rather it is enough to determine the resultant $\vec{R}_{\vec{F}}$ and evaluate its resultant momentum force (torque) applied to the fictive point C.

Combining the above relations, we have:

$$\vec{R}_{\vec{M}}=\vec{r}_C\times\vec{R}_{\vec{F}}=\vec{r}_C\times\left(\sum_{i=1}^{n}F_i\vec{u}\right)=\left(\sum_{i=1}^{n}F_i\right)\vec{r}_C\times\vec{u}=\left(\sum_{i=1}^{n}F_i\vec{r}_C\right)\times\vec{u} \tag{9.3.176}$$

But we showed just before that:

$$\vec{R}_{\vec{M}}=\left(\sum_{i=1}^{n}\vec{r}_iF_i\right)\times\vec{u} \tag{9.3.177}$$

thus by equating:

$$\left(\sum_{i=1}^{n}F_i\vec{r}_C\right)\times\vec{u}=\left(\sum_{i=1}^{n}\vec{r}_iF_i\right)\times\vec{u} \tag{9.3.178}$$

It follows:

$$\sum_{i=1}^{n}F_i\vec{r}_C=\sum_{i=1}^{n}\vec{r}_iF_i \tag{9.3.179}$$

From which we finally draw:

$$\boxed{\vec{r}_C=\frac{\displaystyle\sum_{i=1}^{n}\vec{r}_iF_i}{\displaystyle\sum_{i=1}^{n}F_i}} \tag{9.3.180}$$

as $F_i=m_ia_i$ (Newton's second law) let us now assume (special case but well known in astronomy when we deal with gravitational force at almost constant distance) that $\forall i,j:a_i=a_j$ we can then write this very important result:

$$\vec{r}_C=\frac{\cancel{a_i}\displaystyle\sum_{i=1}^{n}\vec{r}_im_i}{\cancel{a_i}\displaystyle\sum_{i=1}^{n}m_i}=\frac{\displaystyle\sum_{i=1}^{n}\vec{r}_im_i}{\displaystyle\sum_{i=1}^{n}m_i} \tag{9.3.181}$$

We recognize in the last expression the center of mass that we have studied earlier above:

$$\boxed{\vec{r}_G=\frac{\displaystyle\sum_{i=1}^{n}\vec{r}_im_i}{\displaystyle\sum_{i=1}^{n}m_i}} \tag{9.3.182}$$

■ Q.E.D.

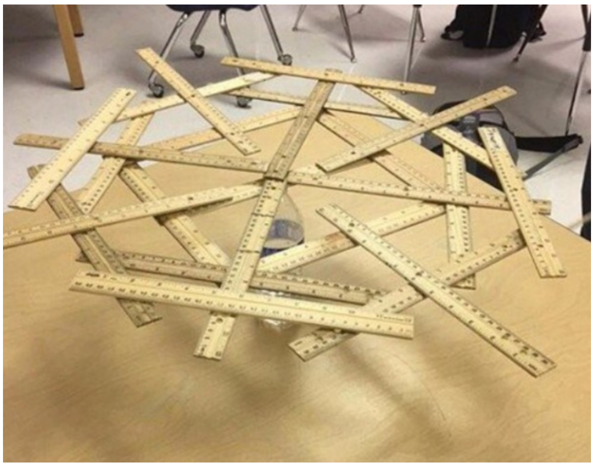

Figure 9.35: **Funny application example of what we have just proved**

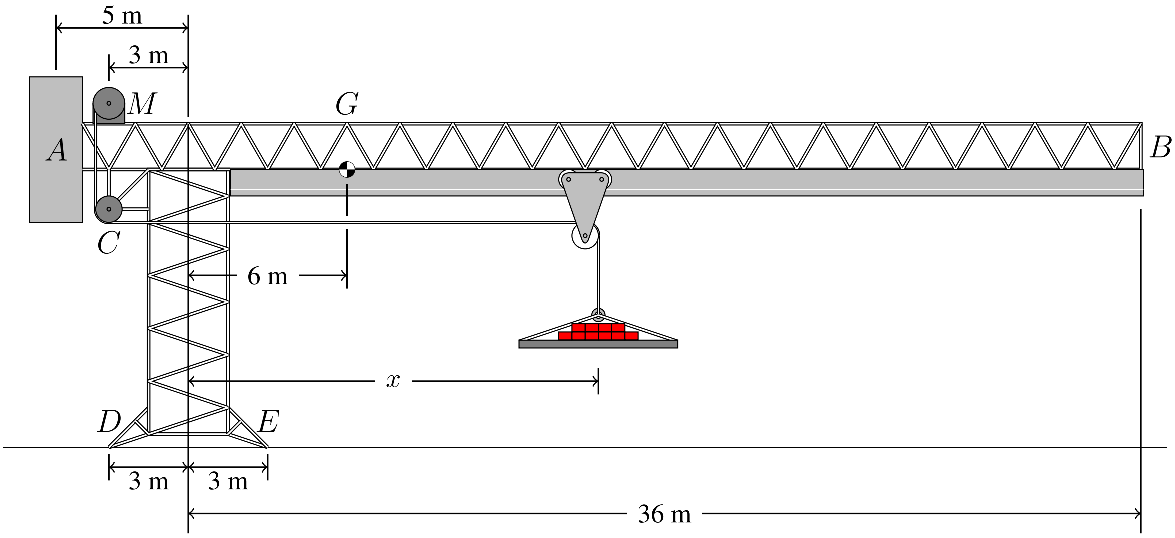
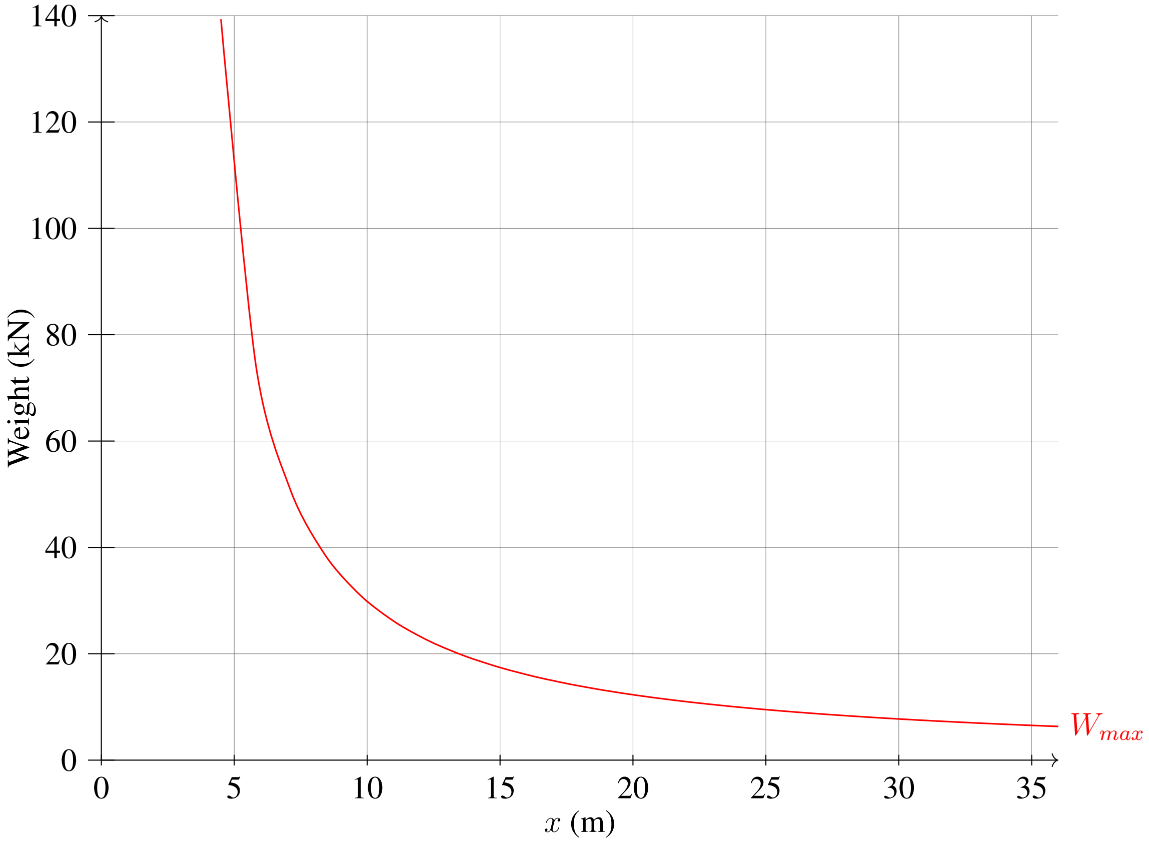
C3. By the third Newton's law, any rigid solid body in stable equilibrium in contact with a set of rigid solids also in stable equilibrium, suffer all of the same equal force at each point of contact (identically distributed) but opposed by these latest (and assimilated through their center of gravity when it is an isotropic and constant vector field that is causing the contact). Therefore:

- The application points of action/reaction forces must be placed on the various points of contact when it is a countable amount of forces that are behind and that are not parallel.
- The application points of action/reaction forces can be places at the center of mass or gravity if the forces causing the contact (verbatim: acceleration) are the source of a gravitational vector field, respectively electrostatic / magnetic (meaning the forces are in a first approximation all parallels).

For example a typical problem in the analysis of the static of forces is to find the maximum weight that a crane could carry as a function of distance before it would tip over (the supports at D and E aren't bolted to the ground).

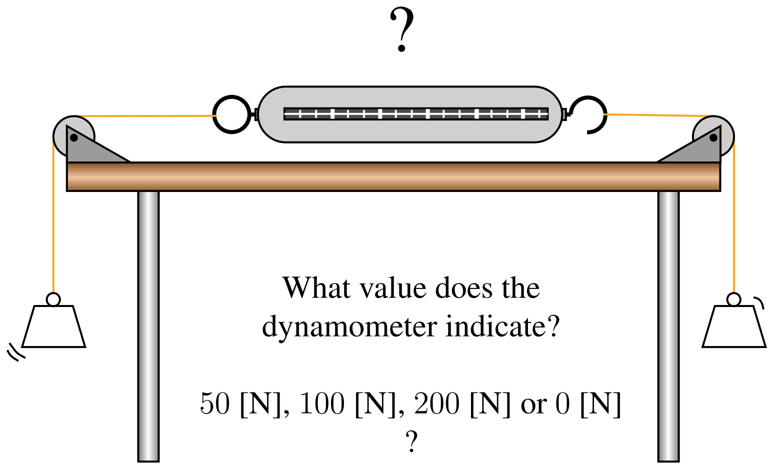




Below, the reader can see a photo of the biggest crane in the world in the early 121st century (Sarens SGC-250, $5,000$ Tonne lifting capacity, 250 [m] tall):

Figure 9.36: **Sarens SGC-250**

A simple example to check if someone masters the basics of static is to show the figure below and ask for an answer:



?
What value does the dynamometer indicate?
50 [N], 100 [N], 200 [N] or 0 [N] ?

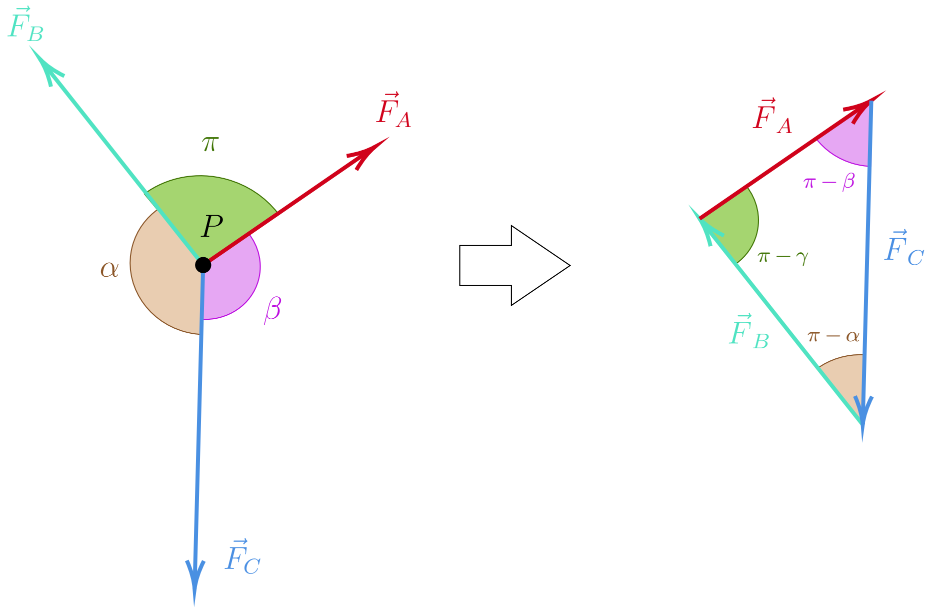
For information the correct answer is 100 [N].

9.3.5.1 Lami's theorem

"Lami's theorem" states that when three coplanar, concurrent, non-collinear forces keep a body in static equilibrium, each force is proportional to the sine of the angle between the other two forces. In formula form, this is expressed as :

$$\frac{F_A}{\sin(\alpha)}=\frac{F_B}{\sin(\beta)}=\frac{F_C}{\sin(\gamma)} \tag{9.3.183}$$

This relationship arises because the three force vectors must form a closed triangle when placed tip-to-tail, and the law of sines (see section Trigonometry page 2528) then applies to that triangle.



$\vec{F}_B$
$\vec{F}_A$
π
P
α
β
$\vec{F}_C$
$\vec{F}_A$
$\pi-\beta$
$\vec{F}_C$
$\pi-\gamma$
$\vec{F}_B$
$\pi-\alpha$

Figure 9.37: Lami's theorem illustrated

Proof 9.4.3. As the vectors must balance $\vec{F}_A+\vec{F}_B+\vec{F}_C=\vec{0}$, hence by making all the vectors touch its tip and tail the result is a triangle with sides F_A, F_B, F_C and angles $180°-\alpha, 180°-\beta, 180°-\gamma$ where α,β,γ are the exterior angles.

By the law of sines then:

$$\frac{F_A}{\sin(180°-\alpha)}=\frac{F_B}{\sin(180°-\beta)}=\frac{F_C}{\sin(180°-\gamma)} \tag{9.3.184}$$

Then by applying that for any angle $\theta, \sin(180°-\theta)=\sin\theta$ (supplementary angles have the same sine), and the result is:

$$\frac{F_A}{\sin(\alpha)}=\frac{F_B}{\sin(\beta)}=\frac{F_C}{\sin(\gamma)} \tag{9.3.185}$$

■ Q.E.D.

Lami's theorem is widely used in statics, mechanical engineering, and structural engineering, especially for analyzing systems where exactly three forces act at a point. Typical applications include trusses, frames, bridges, cranes, and other structures where loads meet at joints or nodes. It is particularly useful for solving equilibrium problems quickly when only three forces are involved and the geometry is known.

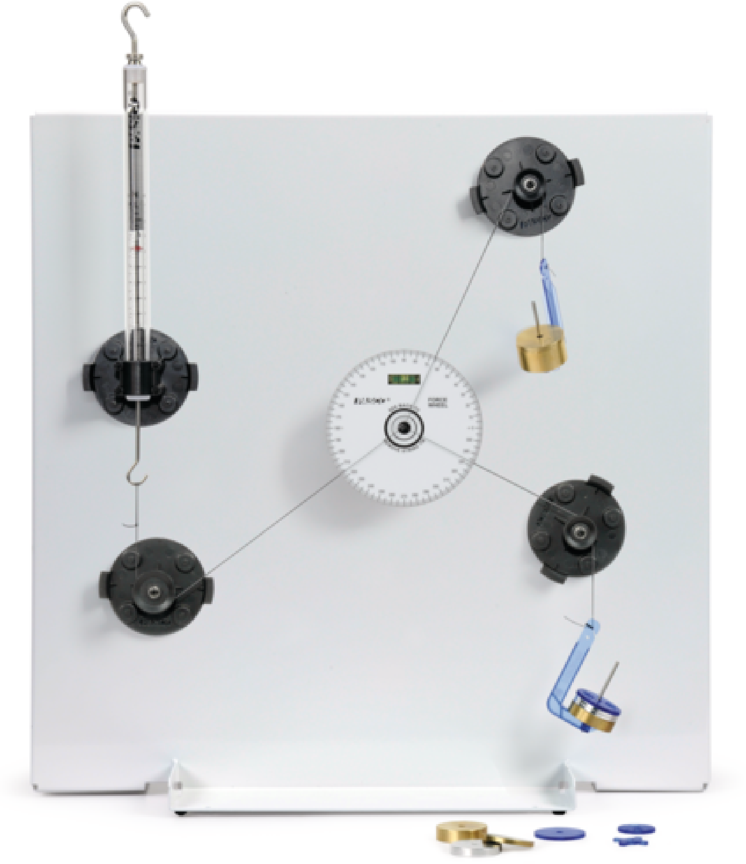


Figure 9.38: **PASCO® scientific static system to check Lami's theorem in schools**

9.3.6 Ballistics

Definition (#9.3.439): "Ballistics" is the science or study of the motion path of a body having an initial velocity through a given medium in space immersed in a given (most of time: constant) field (gravitational, magnetic or electrostatic).

> Remark
>
> We have hesitate, and still do, to write this subject in the section of Spatial Engineering. So it is not impossible that in a near of or far future this subject moves in another section.

We will prove now thanks to our knowledge in kinematics that the parabolic movement is the natural (approximative) movement of a mobile body in the field of gravity in empty space animated (without friction or where friction can be neglected) by a travel speed $\vec{v}_0$ not necessarily parallel to the acceleration of gravity $\vec{g}$ (in general this is therefore a curvilinear motion). For example, a projectile having an initial velocity $\vec{v}_0$ inclined from an angle β from the horizontal:

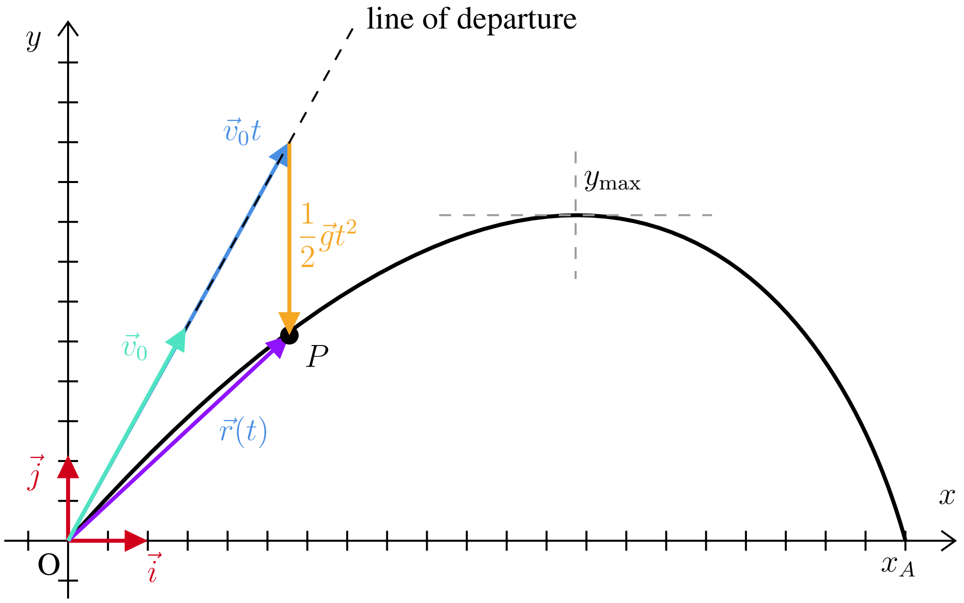

Figure 9.39: **Ballistics configuration study**

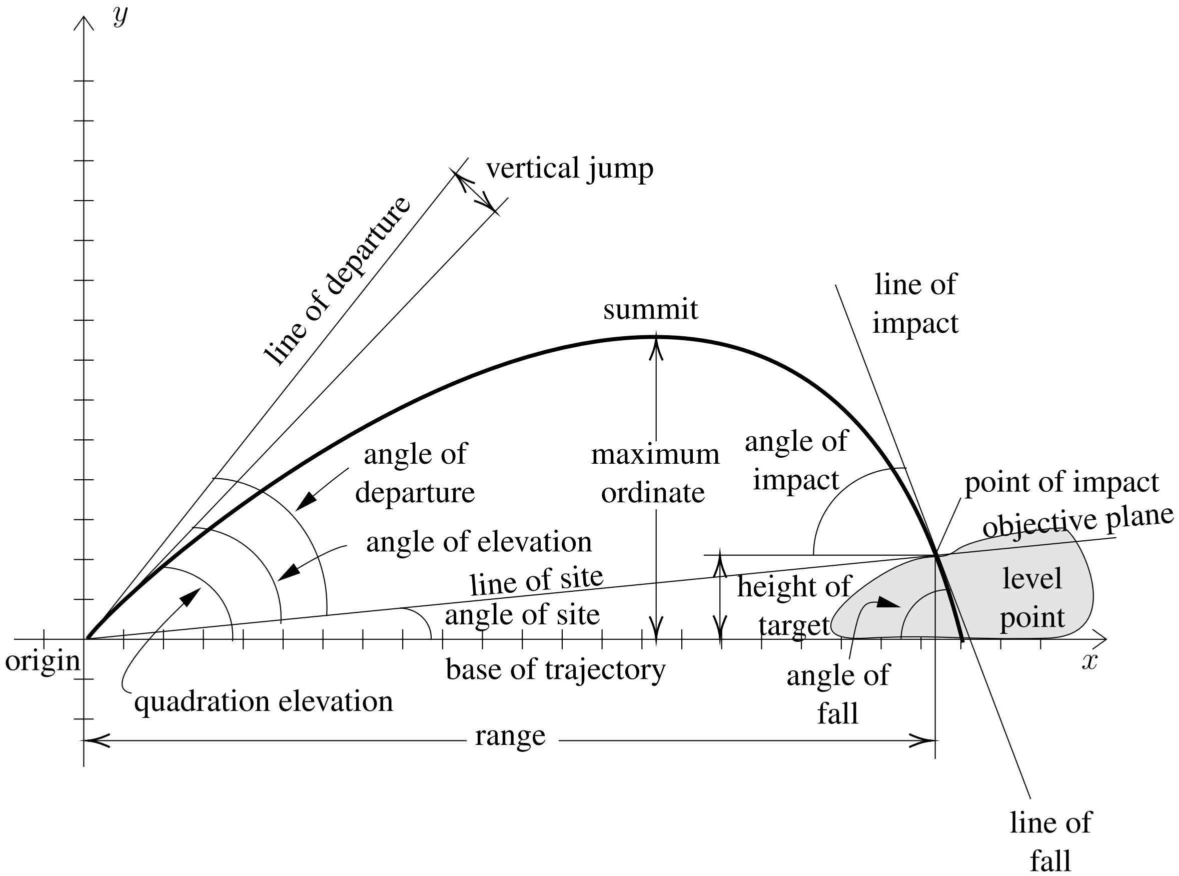
And with some vocabulary stuff associated:



y
vertical jump
line of departure
summit
line of
impact
angle of
departure
maximum
ordinate
angle of
impact
point of impact
objective plane
angle of elevation
line of site
angle of site
height of
target
level
point
origin
base of trajectory
quadration elevation
angle of
fall
x
range
line of
fall

Figure 9.40: **Typical Artillery vocabulary in ballistics**

Obviously the reader can ask himself if the study of ballistics is useful outside artillery?! In fact even if does not apply to rocket launch as their velocity is not constant (boosters) and the application to golf is not quite interesting for engineers we have some practical situation where such calculations are useful. A contemporary one is the "ice ballistic problem" for the security radius around wind turbine to avoid people or houses to receive blocks of ice (in winter) that detach from the pales in rotation at a given rotation speed ω and for sure the trajectories if these ice blocks are ballistic trajectories!!!

For pedagogical reasons we will first do the developments assuming wrongly a flat Earth...

Before we start let us give a definition!

Definition (#9.3.440): An "elevation angle" is the angular measurement between the reference plane tangent to the observer (instrument) position and a line of sight directed toward an object located above that tangent plane.

9.3.6.1 Ballistic equation without friction

In the absence of gravity and friction the mobile P would follow the straight departure line indefinitely. The action of the gravity is to take it down, at time t, of the well known value to us $\dfrac{1}{2}gt^2$.

We put the projection on the axes:

$$\vec{r}(t)=v_0\cos(\beta)t\vec{i}+\left(v_0\sin(\beta)t-\frac{1}{2}gt^2\right)\vec{j} \tag{9.3.186}$$

combination of smooth movement along the x-axes and a falling motion with initial velocity v_{0y} along the y-axes. Which corresponds to the following equations:

$$\begin{aligned}x(t)&=v_0\cos(\beta)t\\ y(t)&=v_0\sin(\beta)t-\frac{1}{2}gt^2\end{aligned} \tag{9.3.187}$$

eliminating the time between these two equations we get the "parabolic trajectory equation (without friction)":

$$\boxed{y=x\tan(\beta)-\frac{g}{2v_0^2\cos^2(\beta)}x^2} \tag{9.3.188}$$

which had already been obtained by Galileo in the early 117th century (holocene calendar).

Remark

Notice that the same relation applies wit the Electric force (in non-relativistic speed) where the acceleration g must simply be replaced by qE/m (see section Electrostatics page 3968).

We calculate also the target range $x_{\max}$ of the projectile by putting $y=0$ in the above equation and we get easily :

$$\boxed{x_{\max}=\frac{v_0^2}{g}\sin(2\beta)} \tag{9.3.189}$$

the solution $x=0$ have no interest.

The maximum height $y_{\max}$ can be calculated by cancelling the derivative of the equation of the trajectory. So we get easily:

$$\boxed{y_{\max}=\frac{v_0^2}{2g}\sin^2(\beta)} \tag{9.3.190}$$

We notice that for the maximum range for a given initial speed we have two typical cases to consider:

1. We give ourselves and unreachable target range $x_{\max}$ as it is not possible that $\sin(\beta)>1$.

2. As we have $\sin(2\beta)$ in the expression of $x_{\max}$ it is obvious that it is $\beta = \pi/4$ ($45°$) that gives the maximum range for a given initial speed.

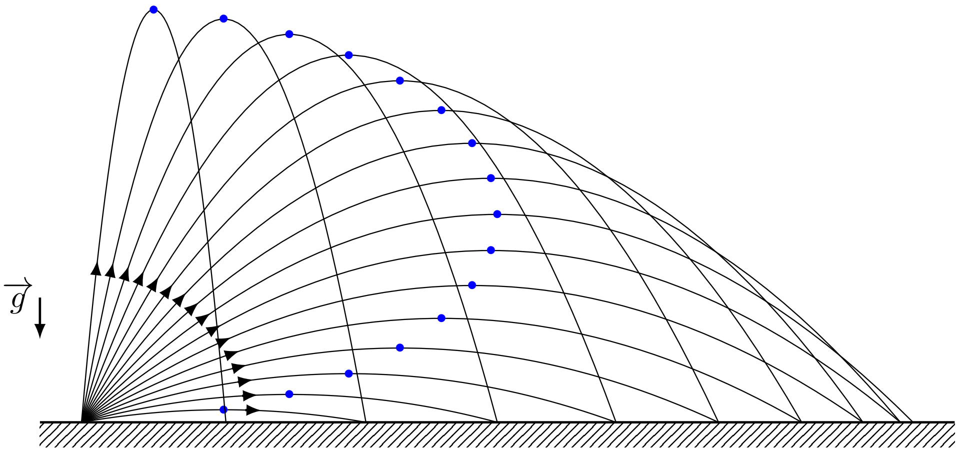


Figure 9.41: **Influence of the angle β on the trajectory (source: Femtophysique)**

The curve enveloping all parables, plotted for a given initial speed v_0 in all possible directions, is still a parable named "safety parabola". Its rotation about the y-axis creates a paraboloid which circumscribes (contains) the region of the space accessible only to projectiles.

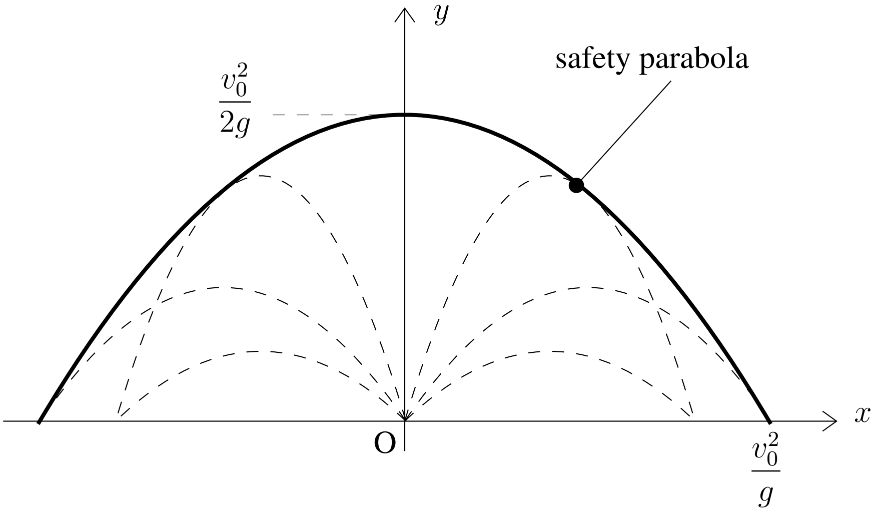

Figure 9.42: **Ballistic safety parabola**

Thus, it is not too difficult to find the equation of this safety parabola !

The vertically shot ($\beta = \pi/4$) is known to us and is given by:

$$v_0 = \sqrt{2gy_{\max}} \Leftrightarrow y_{\max} = \frac{v_0^2}{2g} \tag{9.3.191}$$

The maximal range is as we know given by:

$$x_{\max} = \frac{v_0^2}{g} \tag{9.3.192}$$

So when $x = x_{\max} \Rightarrow y = 0$ such that:

$$y_{\text{safety}} = \frac{v_0^2}{2g} - \frac{g}{2v_0^2}x^2 \tag{9.3.193}$$

which is the equation of the safety parabola.

The time of flight is the time it takes for the projectile to finish its trajectory. As we have for the vertical component:

$$y(t) = v_0 \sin(\beta)t - \frac{1}{2}gt^2 \tag{9.3.194}$$

and the "time of flight" is given when $y = 0$, it comes therefore:

$$v_0 \sin(\beta)t = \frac{1}{2}gt^2 \tag{9.3.195}$$

That is to say:

$$\boxed{t_{\text{flight}} = 2v_0\frac{\sin(\theta)}{g}} \tag{9.3.196}$$

The "angle of reach" is the angle β at which a projectile must be launched in order to go a distance $x_{\max}$, given the initial velocity v_0. So from:

$$x_{\max} = \frac{v_0^2}{g}\sin(2\beta) \tag{9.3.197}$$

We get:

$$\boxed{\beta_{\text{reach}} = \frac{1}{2}\arcsin\left(\frac{x_{\max}g}{v_0^2}\right)} \tag{9.3.198}$$

Ok now much more interesting... To hit a target at range x_T and altitude y_T when fired from $(0,0)$ and with initial speed v_0 the required angle(s) of launch θ are:

$$\theta = \arctan\left(\frac{v_0^2 \pm \sqrt{v^4 - g(gx_T^2 + 2y_Tv_0^2)}}{gx_T}\right) \tag{9.3.199}$$

The two roots of the equation correspond to the two possible launch angles, so long as they aren't imaginary, in which case the initial speed is not great enough to reach the point (x,y) selected.

Proof 9.4.4. First, let us recall that:

$$\begin{aligned} x_T(t) &= v_0\cos(\beta)t \\ y_T(t) &= v_0\sin(\beta)t - \frac{1}{2}gt^2 \end{aligned} \tag{9.3.200}$$

Solving the first for t and substituting this expression in the second gives (using the trigonometric identities proved in the section of Trigonometry):

$$y_T = x_T\tan(\beta) - \frac{gx_T^2}{2v_0^2\cos^2(\beta)} = x\tan(\beta) - \frac{gx_T^2}{2v_0^2}(1+\tan^2(\beta)) \tag{9.3.201}$$

After a small rearrangement:

$$\frac{-gx_T^2}{2v_0^2}\tan^2(\beta)+x\tan(\beta)-\frac{gx_T^2}{2v_T^2}-y_T=0 \tag{9.3.202}$$

Let us put $\Gamma=\tan(\beta)$:

$$\frac{-gx_T^2}{2v_T^2}\Gamma^2+x\Gamma-\frac{gx_T^2}{2v_0^2}-y_T=0 \tag{9.3.203}$$

Solving this second order polynomial as we learned to do it in the section Calculus we have for discriminant (see page 1383) :

$$\Gamma=\frac{-x_T\pm\sqrt{x_T^2-4\left(\frac{-gx_T^2}{2v_0^2}\right)\left(\frac{-gx_T^2}{2v_0^2}-y_T\right)}}{2\left(\frac{-gx_T^2}{2v_0^2}\right)} \tag{9.3.204}$$

So we get after simplifications:

$$\tan(\beta)=\frac{v_0^2\pm\sqrt{v_0^4-g(gx_T^2+2y_Tv_0^2)}}{gx_T} \tag{9.3.205}$$

Hence:

$$\boxed{\beta=\tan^{-1}\left(\frac{v_0^2\pm\sqrt{v_0^4-g(gx_T^2+2y_Tv_0=^2)}}{gx_T}\right)} \tag{9.3.206}$$

If instead of a coordinate (x,y) it is required to hit a target at distance r and angle of elevation θ (polar coordinates), we use the relations $x_T=r_T\cos(\theta_T)$, $y_T=r_T\sin(\theta_T)$ and substitute to get:

$$\beta=\tan^{-1}\left(\frac{v_0^2\pm\sqrt{v_0^4-g(gr_T^2\cos^2(\theta_T)+2v_0^2r_T\sin(\theta_T))}}{gr_T\cos(\theta_T)}\right) \tag{9.3.207}$$

■ Q.E.D.

Remark

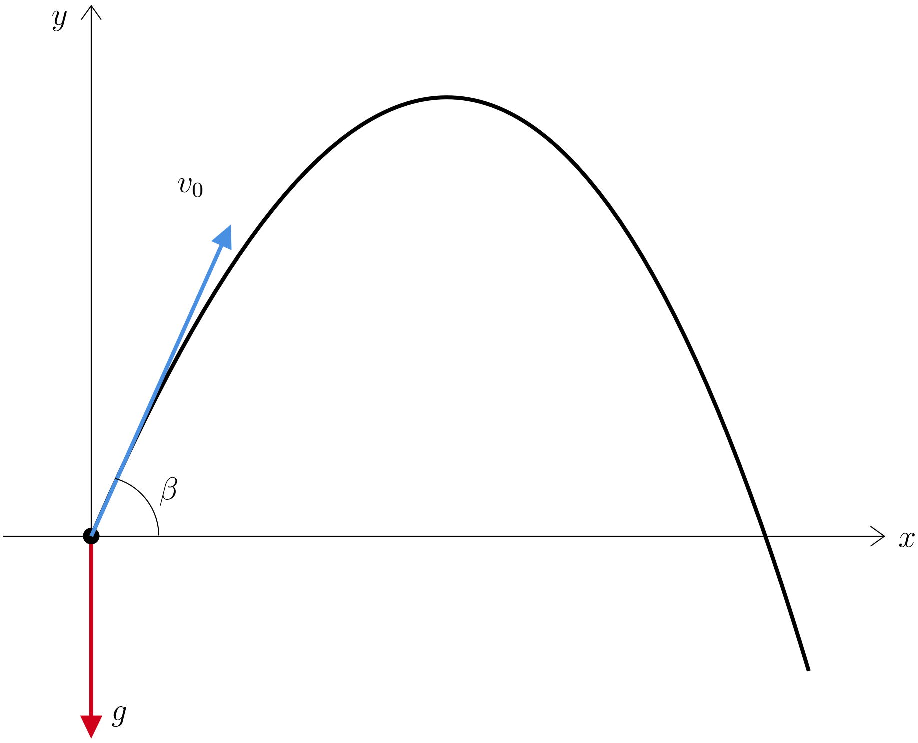
Keep in mind that if what interest you is the horizontal distance traveled by an item with an initial angle $\beta=0$ and initial speed v_0 under gravity g and without friction (in vacuum) from a height h, then we have:

$$x_{\max}=x_0+v_0t+\frac{1}{2}at^2=v_0t=v_0\sqrt{\frac{2h}{g}} \tag{9.3.208}$$

Therefore from a height of $h=1.70$ [m], we have $x_{\max}\cong v_0\cdot 0.58$. So as a breath is estimated at $v_0\cong 1\,[\text{m}\cdot\text{s}^{-1}]$, and sneeze germs at $v_0\cong 40\,[\text{m}\cdot\text{s}^{-1}]$, and a cough at $v_0\cong 10\,[\text{m}\cdot\text{s}^{-1}]$ just do the maths...

9.3.6.2 Ballistic equation with friction

Suppose that a projectile of mass m is launched, at $t=0$, from ground level (in a flat plain), making an angle β to the horizontal. Suppose, further, that, in addition to the force of gravity, the projectile is subject to an air resistance force which acts in the opposite direction to its instantaneous direction of motion, and whose magnitude is directly proportional to its instantaneous speed. This is not a particularly accurate model of the drag force (see section Fluid Mechanics page 3856) due to air resistance (the magnitude of the drag force is typically proportion to the square of the speed), but it does lead to tractable equations of motion...



Consider now the motion of the point mass in the presence of a resistant force proportional to the point velocity, i.e., of the form $-bv$, with $b>0$ denoting a suitable parameter. In this case Newton's law can be cast in the following form:

$$a=g-\frac{1}{\tau}v \tag{9.3.209}$$

Let us denote that:

$$\vec{a}=\vec{g}-\frac{1}{\tau}\vec{v} \tag{9.3.210}$$

where $\vec{v}=(v_x,v_y)$ is the projectile velocity, $\vec{g}=(0,-g)$ the acceleration due to gravity. In component form the above equation becomes:

$$\begin{aligned}\frac{\mathrm{d}v_x}{\mathrm{d}t}&=-g\frac{v_x}{v_T}\\ \frac{\mathrm{d}v_y}{\mathrm{d}t}&=-g\left(1+\frac{v_y}{v_T}\right)\end{aligned} \tag{9.3.211}$$

where $v_T = mg/b$ is named the "terminal velocity" i.e., the velocity at which the drag force balances the gravitational force (for a projectile falling vertically downward).

In component form, the above equation becomes:

$$\begin{aligned}\frac{\mathrm{d}v_x}{\mathrm{d}t} &= -g\frac{v_x}{v_T}\\ \frac{\mathrm{d}v_y}{\mathrm{d}t} &= -g\left(1+\frac{v_y}{v_T}\right)\end{aligned} \tag{9.3.212}$$

Integrating the first equation above we get:

$$\int\limits_{v_{x0}}^{v} \frac{dv_x}{v_x} = -\frac{g}{v_T}t \tag{9.3.213}$$

Here $v_{x0} = v_0\cos(\beta)$ is the initial x-component of the launch velocity. Hence:

$$v_x = v_0\cos(\beta)e^{-gt/v_T} \tag{9.3.214}$$

And integration yields to (this takes into account that the constant of integration must satisfy $x(0) = 0$:

$$x = \frac{v_0 v_T\cos(\beta)}{g}\left(1-e^{-gt/v_T}\right) \tag{9.3.215}$$

In the limit $t \ll v_T/g$, the above relation reduces to:

$$x = v_0\cos(\beta t) \tag{9.3.216}$$

Which is the standard result in the absence of air drag. In the opposite limit, $t \gg v_T/g$, we get:

$$x = \frac{v_0 v_T\cos(\beta)}{g} \tag{9.3.217}$$

The above expression clearly sets an effective upper limit on how far the projectile can travel in the horizontal direction!

Now let us come back to the y component! Remember that:

$$\begin{aligned}\frac{\mathrm{d}v_x}{\mathrm{d}t} &= -g\frac{v_x}{v_T}\\ \frac{\mathrm{d}v_y}{\mathrm{d}t} &= -g\left(1+\frac{v_y}{v_T}\right)\end{aligned} \tag{9.3.218}$$

Integrating the second equation will be written:

$$\int\limits_{v_{y0}}^{v_z} \frac{\mathrm{d}v_y}{v_T+v_y} = -\frac{g}{v_T}t \tag{9.3.219}$$

where $v_{y0} = v_0\sin(\beta)$ is the y-component of the launch velocity. Hence:

$$\ln\left(\frac{v_T+v_y}{v_T+v_{y0}}\right) = -\frac{g}{v_T} \tag{9.3.220}$$

or:

$$v_y = v_0 \sin(\beta) e^{-gt/v_T} - v_T \left(1 - e^{-gt/v_T}\right) \tag{9.3.221}$$

Integration gives:

$$y = \frac{v_T}{g}\left(v_0 \sin(\beta) + v_T\right)\left(1 - e^{-gt/v_T}\right) - v_T t \tag{9.3.222}$$

In the limit $t \ll v_T/g$, this equation reduces to:

$$y = v_0 \sin(\beta) t - \frac{g}{2} t^2 \tag{9.3.223}$$

which is similar to the standard result in the absence of air drag. In the opposite limit, $t \gg v_T/g$, we get:

$$y = \frac{v_T}{g}\left(v_0 \sin(\beta) + v_T\right) - v_T t \tag{9.3.224}$$

So finally:

$$\boxed{\begin{aligned} x &= \frac{v_0 v_T \cos(\beta)}{g}\left(1 - e^{-gt/v_T}\right) \\ y &= \frac{v_T}{g}\left(v_0 \sin(\beta) + v_T\right) - v_T t \end{aligned}} \tag{9.3.225}$$

We know that in the absence of air resistance, the maximum horizontal range is achieved when the launch angle β takes the value $45°$ ($\pi/4$ [rad]).

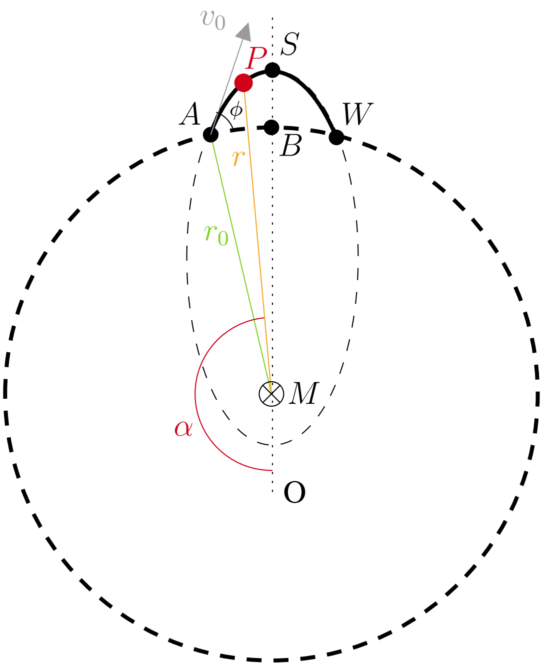
On the other hand in the presence of air resistance, the maximum horizontal range is achieved when β is made as small as possible!

9.3.6.3 Ballistic accounting Earth's curvature

We will focus now on the trajectory in a vacuum, taking into account the decrease of gravity with the height and the convergence of vertical lines from the curvature of the Earth.

The text that follows is almost a simple copy/paste with some improvements of the very good book *Handbook of Ballistics, Volume I.* of Dr C. Cranz, Cpt. K. Becker (11921 according to holocene calendar) from page 22 to 33 (see [156]).

Take the center M of the Earth (as in the figure below) as the pole in a system of polar coordinates; and let any arbitrary point P have the polar coordinates $\overline{MP} =$ radius vector r, and $\angle \text{O}MP =$ polar angle α; the direction OM of the polar axis from which the polar angle α is measured may be left undetermined at first:



At A, the point of departure of the shell, let $r=r_0=$ radius of the Earth, $6,370,300$ [m]; let the initial velocity be v_0, and the angle of departure ϕ.

According to Newton's law of gravitation (see section Astronomy page 5255), the acceleration of gravity is given by:

$$a=g\frac{r_0^2}{r^2}:=\frac{\mu}{r^2} \tag{9.3.226}$$

Moreover by second Kepler's law/area law (see section Astronomy page 5234):

$$r^2\frac{\mathrm{d}\alpha}{\mathrm{d}t} \tag{9.3.227}$$

is a constant, that we will denote here C, along the whole path of flight ; the value of (rearrangement of the previous relation):

$$r\frac{\mathrm{d}\alpha\cdot r}{\mathrm{d}t} \tag{9.3.228}$$

at the point A is given by (tangential velocity):

$$C=r_0v_0\cos(\phi) \tag{9.3.229}$$

since here:

$$r\mathrm{d}\alpha=\cos(\phi)\mathrm{d}s \tag{9.3.230}$$

where $\mathrm{d}s$ is the element of arc, and:

$$\frac{\mathrm{d}s}{\mathrm{d}t}=v_0 \tag{9.3.231}$$

we have:

$$r^2\frac{\mathrm{d}\alpha}{\mathrm{d}t}=C=r_0v_0\cos(\phi) \tag{9.3.232}$$

Further, in the motion of the shell along its path:

$$\frac{\mathrm{d}v}{\mathrm{d}t}=-\frac{\mu}{r^2}\frac{\mathrm{d}r}{\mathrm{d}s} \quad (9.3.233)$$

Or after rearranging:

$$v\frac{\mathrm{d}v}{\mathrm{d}r}=-\frac{\mu}{r^2} \quad (9.3.234)$$

Rearranging:

$$v\mathrm{d}v=-\frac{\mu}{r^2}\mathrm{d}r \quad (9.3.235)$$

and integrating from A to P and rearranging:

$$v^2-v_0^2=-2\mu\int\limits_{r_0}^{r} r^{-2}\mathrm{d}r=2\mu\left(\frac{1}{r}-\frac{1}{r_0}\right) \quad (9.3.236)$$

That we can rewrite:

$$v^2=q+\frac{2\mu}{r} \quad (9.3.237)$$

where:

$$q=v_0^2-\frac{2\mu}{r_0} \quad (9.3.238)$$

Since (see section Vector Calculus page 1865):

$$v^2=\left(\frac{\mathrm{d}s}{\mathrm{d}t}\right)^2=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\alpha}{\mathrm{d}t}\right)^2 \quad (9.3.239)$$

and from:

$$r^2\frac{\mathrm{d}\alpha}{\mathrm{d}t}=C=r_0v_0\cos(\phi) \quad (9.3.240)$$

We have:

$$\frac{\mathrm{d}r}{\mathrm{d}t}=\frac{\mathrm{d}r}{\mathrm{d}\alpha}\frac{\mathrm{d}\alpha}{\mathrm{d}t}=\frac{\mathrm{d}r}{\mathrm{d}\alpha}\frac{C}{r^2} \quad (9.3.241)$$

Therefore:

$$v^2=\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)^2+r^2\left(\frac{\mathrm{d}\alpha}{\mathrm{d}t}\right)^2 \quad (9.3.242)$$

may be written:

$$v^2=q+\frac{2\mu}{r}=\left(\frac{\mathrm{d}r}{\mathrm{d}\alpha}\right)^2\frac{C^2}{r^4}+\frac{C^2}{r^2} \quad (9.3.243)$$

Or after rearranging:

$$\mathrm{d}\alpha=\frac{\dfrac{C}{r^2}\mathrm{d}r}{\sqrt{q+\dfrac{2\mu}{r}-\dfrac{C^2}{r^2}}}=\frac{-\mathrm{d}\dfrac{\dfrac{C}{r}-\dfrac{\mu}{C}}{\sqrt{q+\frac{\mu^2}{C^2}}}}{\sqrt{1-\left[\dfrac{\dfrac{C}{r}-\dfrac{\mu}{C}}{\sqrt{\left(q+\dfrac{\mu^2}{C^2}\right)}}\right]^2}} \tag{9.3.244}$$

This is the differential equation of the path of the shell, with r and α as the two variables. Integration gives (see section Differential and Integral Calculus page 1534):

$$\alpha-\gamma=\cos^{-1}\left(\frac{\dfrac{C}{r}-\dfrac{\mu}{C}}{\sqrt{q+\dfrac{\mu^2}{C^2}}}\right) \tag{9.3.245}$$

Hence after rearranging:

$$r=\frac{C}{\dfrac{\mu}{C}+\sqrt{q+\dfrac{\mu^2}{C^2}}\cos(\alpha-\gamma)} \tag{9.3.246}$$

That can be rewritten as:

$$r=\frac{p}{1+e\cos(\alpha-\gamma)} \tag{9.3.247}$$

if we put:

$$p=\frac{C^2}{\mu},\qquad e=\sqrt{1+\frac{qC^2}{\mu^2}} \tag{9.3.248}$$

We recognize that:

$$r=\frac{p}{1+e\cos(\alpha-\gamma)} \tag{9.3.249}$$

is the conic section equation (see section Analytical Geometry page 2782) in which we have parameter:

$$p=\frac{b^2}{a}=\frac{a^2-d^2}{a}=a-e\cdot d=a-e^2a=a\left(1-e^2\right) \tag{9.3.250}$$

where a and b are the two semi-axes, a the one that contains the focus, d the distance between center and focus of the conic section, e is the eccentricity.

One focus M is here the pole of the system of polar coordinates, and the polar angle α is measured from that vertex O of the major axis that lies nearest to the focus M; with $e<1$ we have an ellipse; with $e=0$, a circle; $e=1$ a parabola; $e>1$ an hyperbola.

When the integration constant γ is zero, the polar axis OM of the polar coordinate system is the line joining the perihelion O to the center of the Earth. We have then:

$$\begin{gathered}r=\frac{p}{1+e\cos(\alpha)}\\ v^2=v_0^2-\frac{2\mu}{r_0}+\frac{2\mu}{r}\end{gathered} \tag{9.3.251}$$

where:

$$p=\frac{C^2}{\mu},\qquad e=\sqrt{1+\frac{qC^2}{\mu^2}} \tag{9.3.252}$$

and:

$$q=v_0^2-\frac{2\mu}{r_0},\qquad \mu=gr_0^2,\qquad C=r_0v_0\cos(\phi),\qquad r_0=6,370,300\,[\text{m}] \tag{9.3.253}$$

Since r_0,ϕ,v_0, are known, and also C,μ,q,e,p, we are in a position to determine for any value of α the corresponding distance r of the shell from the center of the Earth from:

$$r=\frac{p}{1+e\cos(\alpha)} \tag{9.3.254}$$

and from:

$$v^2=v_0^2-\frac{2\mu}{r_0}+\frac{2\mu}{r} \tag{9.3.255}$$

the corresponding velocity v in the trajectory; the time of flight is obtained then from the integration of:

$$\mathrm{d}t=\frac{r^2\mathrm{d}\alpha}{C} \tag{9.3.256}$$

The trajectory is an ellipse when $e<1$, that is when:

$$\sqrt{1+\frac{C^2}{\mu^2}\left(v_0^2-\frac{2\mu}{r_0}\right)}<1,\ \text{or } v_0<\sqrt{\frac{2\mu}{r_0}} \tag{9.3.257}$$

Now:

$$\sqrt{\frac{2\mu}{r_0}}=\sqrt{2\cdot(9.81)\cdot 6,370,300}=11,050\,[\text{m}\cdot\text{s}^{-1}] \tag{9.3.258}$$

so that the path is an ellipse so long as v_0 remains $<11,050\,[\text{m}\cdot\text{s}^{-1}]$.

This elliptic orbit is a circle in the special case when $e=0$, or:

$$\sqrt{1+\frac{r_0^2v_0^2\cos^2(\phi)}{\mu^2}\left(v_0^2-\frac{2\mu}{r_0}\right)}=0 \tag{9.3.259}$$

Let us put:

$$\frac{r_0v_0^2}{\mu}=z \tag{9.3.260}$$

This equation becomes a second order polynomial:

$$z^2-2z+\frac{1}{\cos^2(\phi)}=0 \qquad (9.3.261)$$

Whose roots are (see section Calculus page 1382):

$$z=\frac{r_0{v_0}^2}{\mu}=1\pm\sqrt{1-\frac{1}{\cos^2(\phi)}} \qquad (9.3.262)$$

and this expression is real only when $\cos(\phi)=\pm1, \phi=0$ or π; in that case:

$$\frac{r_0v_0^2}{\mu}=1 \qquad (9.3.263)$$

Therefore:

$$v_0=\sqrt{\frac{\mu}{r_0}}=7,900\,[\mathrm{m}\cdot\mathrm{s}^{-1}] \qquad (9.3.264)$$

Thus under the specified assumptions the trajectory with any ordinary initial velocity v_0 is an ellipse; it is a parabola when $v_0=11,050\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$; with still greater initial velocity it would be an hyperbola.

The trajectory can be a circle only in the special case when the shell is fired horizontally, with an initial velocity of about $7,900\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$.

To calculate the range $\overline{AW}$ and the vertex ordinate $\overline{BS}$ of an elliptic trajectory from A, we should proceed as follows: first calculate the polar angle $\alpha=\angle\mathrm{O}MA$, which corresponds to the point A, from the relation:

$$r_0=\frac{p}{1+e\cos(\alpha_0)} \qquad (9.3.265)$$

which holds if A is to lie on the trajectory.

Twice the supplement of this angle is the polar angle $\angle AMW$; from this and r_0, the range $\overline{AW}$ can be calculated.

Further, the vertex ordinate $\overline{BS}$ of the trajectory $=\overline{MS}-r_0$, in which $\overline{MS}$ denotes the maximum value of r; this is when the denominator in:

$$r=\frac{p}{1+e\cos(\alpha)} \qquad (9.3.266)$$

assumes its least value, that is when $\cos(\alpha)=-1$. C'est-à-dire:

$$r_{\max}=\frac{p}{1-e} \qquad (9.3.267)$$

and:

$$r_{\min}=\frac{p}{1+e}=\overline{M\mathrm{O}} \qquad (9.3.268)$$

and thus the major axis of the ellipse is given by $r_{\max}+r_{\min}$. Thus:

$$\overline{BS}=\frac{p}{1-e}-r_0 \qquad (9.3.269)$$

✍**Example:**

Let us consider:

$$v_0=820\,[\mathrm{m}\cdot\mathrm{s}^{-1}]=2,952\,[\mathrm{km}\cdot\mathrm{h}^{-1}],\qquad \phi=44^\circ,\qquad r_0=6,370,300\,[\mathrm{m}] \tag{9.3.270}$$

Then:

$$e=\sqrt{1+\frac{qC^2}{\mu^2}}=\sqrt{1+\frac{v_0^2\cos^2(\phi)}{g^2r_0^2}\left(v_0^2-2gr_0\right)}=0.99445 \tag{9.3.271}$$

and:

$$\begin{aligned}\alpha_0&=\cos^{-1}\left(\frac{\frac{C}{r_0}-\frac{\mu}{C}}{\sqrt{q+\frac{\mu^2}{C^2}}}\right)=\cos^{-1}\left(\frac{v_0\cos(\phi)-\frac{gr_0}{v_0\cos(\phi)}}{\sqrt{v_0^2-2gr_0+\frac{g^2r_0^2}{v_0^2\cos(\phi)}}}\right)\\&=179^\circ41'23''26\cong 179.68972^\circ\end{aligned} \tag{9.3.272}$$

Hence:

$$\overline{AW}=\frac{2\cdot(180-\alpha_0)}{360^\circ}2\pi r_0\cong 68,995\,[\mathrm{m}] \tag{9.3.273}$$

with vertex height:

$$\overline{BS}=\frac{p}{1-e}=\frac{C^2/\mu}{1-e}\cong 16,620\,[\mathrm{m}] \tag{9.3.274}$$

On the other hand, in the parabolic path with the same v_0 and ϕ, the range will be $68,500\,[\mathrm{m}]$, and the vertex height $16,538\,[\mathrm{m}]$.

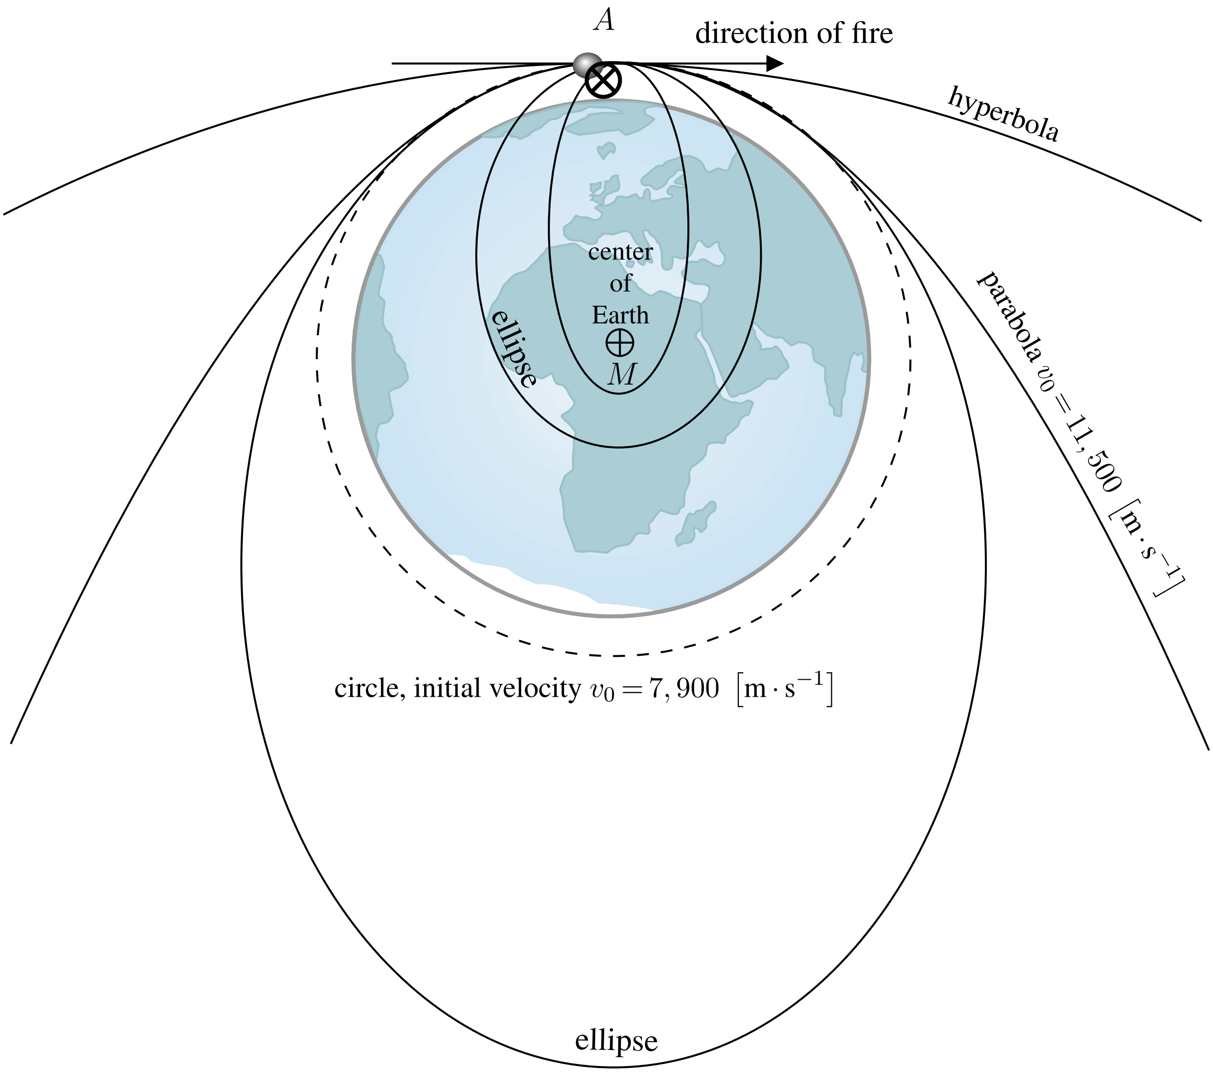
Hence the curvature of the Earth makes an alteration range of:

$$68,995-68,500=495\,[\mathrm{m}] \tag{9.3.275}$$

We therefore understand better why military have to take into account the curvature for long distance missiles!

It is interesting to discuss the trajectories if a shell is fired from the same point always in the same direction, but with increasing initial velocities v_0.

It is assumed in the figure below that shells are fired horizontally from an elevation A in the neighbourhood of the surface of the Earth.



A
direction of fire
hyperbola
parabola $v_0 = 11,500\ \left[\mathrm{m}\cdot\mathrm{s}^{-1}\right]$
center of Earth
M
ellipse
circle, initial velocity $v_0 = 7,900\ \left[\mathrm{m}\cdot\mathrm{s}^{-1}\right]$
ellipse

This is the famous "Newton's cannonball" that was a thought experiment Isaac Newton used to hypothesize that the force of gravity was universal, and it was the key force for planetary motion. It appeared in his posthumously published 11728 (holocene calendar) work *De mundi systemate* (also published in English as *A Treatise of the System of the World*).

As the initial velocity v_0 increases, so the ellipse broadens; the focus moves from A towards M; with $v_0 = 7,900\,\left[\mathrm{m}\cdot\mathrm{s}^{-1}\right]$ the shell describes a circular path round the Earth, in perpetual motion, and the movable focus comes into coincidence with the fixed focus M. In this case the shell flies round always at the same distance from the ground.

When the initial velocity increases still more, the shell at first goes further from the Earth's surface, in an ellipse, but returns again to A the point of departure. At the opposite side of the Earth the shell recedes more and more from the Earth's surface; the movable focus goes back beyond M, on the prolongation of the line AM.

With the velocity $v_0 = 11,050\,[\text{m}\cdot\text{s}^{-1}]$ the shell does not come back to A; the ellipse is changed into a parabola; the movable focus has receded to infinity.

As soon as this initial velocity $11,050\,[\text{m}\cdot\text{s}^{-1}]$ is exceeded, the trajectory is an hyperbola, the branch of which through A approximates more and more to the horizontal direction; the movable focus then approaches A on the line AM produced backward.

This result is of major importance for our study in the section of Aerospace Engineering of gravity assist where all practical cases involve hyperbolics trajectories (the only exception would be a theoretical, ideal case where the spacecraft has exactly the escape velocity, in which case the trajectory would be a parabola)!

9.3.7 Kinematics of Circular Motion (rotational kinematics)

The motion of objects as they translate – move bodily from one place to another – follows a simple set of rules. It turns out that a very similar set of rules describes the motion of objects as the rotate – spin around in place.

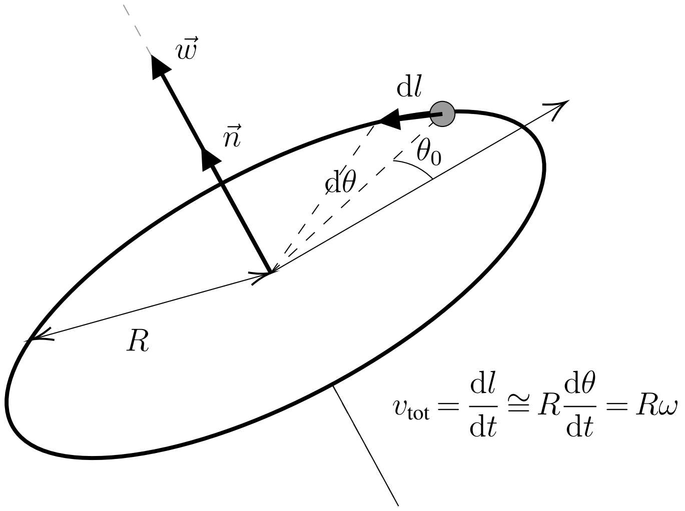
Most situations we have considered so far involve the type of motion named "translation" (pick it up and put it down somewhere else).

But centrifuges, planets, space stations, satellites, molecules, motor engines exhibit a different sort of motion: rotation (spit in place)!

The circular movement, also named "rotation movements", thus describe the rotation of an object around an axis (or a point to make simpler). The usage is to define it with the following information:

- The direction of the axis of rotation plane in space
- The direction of rotation on the constant radius circle around this axis
- The speed v on the circular path.

All this can be summarized in the following figure:



$\vec{w}$
$\mathrm{d}l$
$\vec{n}$
θ_0
$\mathrm{d}\theta$
R
$v_{\text{tot}}=\dfrac{\mathrm{d}l}{\mathrm{d}t}\cong R\dfrac{\mathrm{d}\theta}{\mathrm{d}t}=R\omega$

where for:

$$\boxed{v_{\text{rot}}=\frac{\mathrm{d}l}{\mathrm{d}t}\cong R\frac{\mathrm{d}\theta}{\mathrm{d}t}=R\omega} \tag{9.3.276}$$

we have used the relation proved in the section of Trigonometry (it is just logical by definition if the angle is measured in radians):

$$\mathrm{d}l=R\mathrm{d}\theta \tag{9.3.277}$$

It is therefore absolutely nonsense to express a rotation speed in "distance-per-unit-time" if the radius is not mentioned. A rotation speed of an object must be expressed in radians (or degrees) per unit-time if the dimension of the rotation radius is not explicitly given!

We summarize these three directions by the data given by a vector "instantaneous angular velocity":

$$\vec{\omega}=\omega\vec{n} \tag{9.3.278}$$

The direction of rotation is said to be "positive" when the thumb drawn in the direction of the unit vector $\vec{n}$, we take the axis of the right hand and one sees the object rotate in the direction of the other four fingers ("right hand rule"):

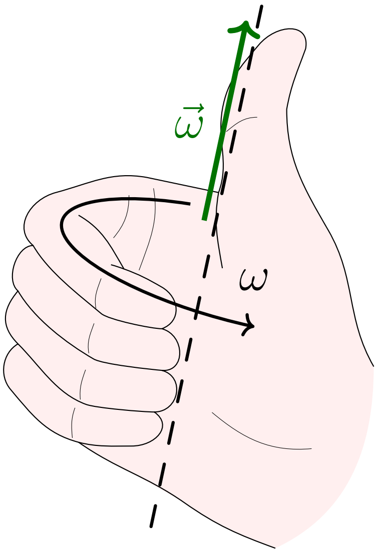


Figure 9.43: **Angular momentum right-handed rule (author: Izaak Neutelings)**

The norm of the instantaneous angular speed, represents obviously the angle traveled per unit of time,by the object that moves in the plane perpendicular to the unit vector $\vec{n}$:

$$\boxed{\omega=\frac{\mathrm{d}\theta}{\mathrm{d}t}} \tag{9.3.279}$$

Of course, it goes without saying that the angular velocity is given in radians per second and not in revolutions per minute or degrees per second!!! We must therefore be careful to always do the right conversion!

Remarks

R1. In the general case of the circular motion, angular velocity of the object studied varies over time: $\omega=\omega(t)$.

R2. When the direction of the rotation axis changes, the components of unit vector $\vec{n}$ are functions of time. This is the case of a motorcycle wheel in a turn for example.

If $\mathrm{d}t$ is the time required for this movement, the curvilinear velocity of the point is therefore:

$$v=\frac{\mathrm{d}l}{\mathrm{d}t}=R\frac{\mathrm{d}\theta}{\mathrm{d}t}=\omega R:=v_{\text{rot}} \tag{9.3.280}$$

then we fall back on the result already given previously.

Now let us do the same that during our study of the rectilinear uniform movement and let us determine the angular position over time. Then we have:

$$\omega=\frac{\mathrm{d}\theta}{\mathrm{d}t}\Rightarrow\mathrm{d}\theta=\omega\mathrm{d}t \tag{9.3.281}$$

Therefore:

$$\int\limits_{\theta_0}^{\theta}\mathrm{d}\theta=\int\limits_{\theta_0}^{t}\omega\mathrm{d}t\Rightarrow\theta-\theta_0=\omega t-\omega t_0 \tag{9.3.282}$$

and if $t_0=0$, then we have:

$$\boxed{\theta=\theta_0+\omega t} \tag{9.3.283}$$

to be compared with the equivalent relation between position and speed obtained during our study of rectilinear kinematics.

Now let us consider the definition of "angular acceleration" (the traditional notation is a bit unfortunate ...):

$$\alpha=\dot{\omega}=\frac{\mathrm{d}\omega}{\mathrm{d}t}=\frac{\mathrm{d}^2\theta}{\mathrm{d}^2}=\ddot{\theta} \tag{9.3.284}$$

Then we have:

$$\alpha=\frac{\mathrm{d}\omega}{\mathrm{d}t}\Rightarrow\mathrm{d}\omega=\alpha\mathrm{d}t \tag{9.3.285}$$

and therefore:

$$\int\limits_{\omega_0}^{\omega}\mathrm{d}\omega=\int\limits_{t_0}^{t}\alpha\mathrm{d}t\Rightarrow\omega-\omega_0=\alpha t-\alpha t_0 \tag{9.3.286}$$

and if $t_0=0$, then we have:

$$\omega=\omega_0+\alpha t \tag{9.3.287}$$

What we can write:

$$\dot{\theta}=\frac{\mathrm{d}\theta}{\mathrm{d}t}=\omega_0+\alpha t \tag{9.3.288}$$

Therefore it comes:

$$\int_{t_0}^{t} \mathrm{d}\theta = \int_{t_0}^{t} (\omega_0 + \alpha t)\mathrm{d}t = \int_{t_0}^{t} \omega_0 \mathrm{d}t + \int_{t_0}^{t} \alpha t \mathrm{d}t \tag{9.3.289}$$

Hence:

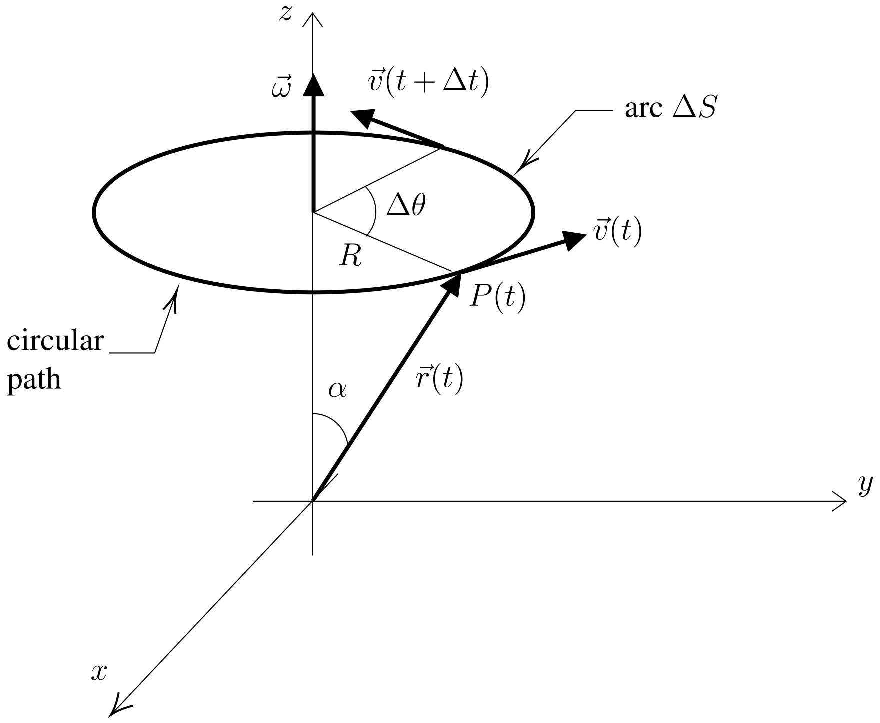
$$\theta(t) - \theta_0 = \omega_0(t - t_0) + \frac{1}{2}\alpha(t^2 - t_0^2) \tag{9.3.290}$$

and if $t_0 = 0$, then we have:

$$\boxed{\theta(t) = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2} \tag{9.3.291}$$

compared with the equivalent relation between position, velocity and acceleration obtained in our study of the kinematics of rectilinear motions.

Let us now look to the vector of circular motion which will be extremely important one step further and also in many other chapters. So given an Euclidean orthonormal basis such as:



We see well from the above figure that:

$$\|\vec{r}(t)\| \sin(\alpha) = R \tag{9.3.292}$$

So finally we have:

$$v = \omega R = \omega \|\vec{r}(t)\| \sin(\alpha) = \|\vec{\omega}\| \cdot \|\vec{r}(t)\| \sin(\alpha) \tag{9.3.293}$$

We see then that we are dealing with a cross product (see section Vector Calculus page 1830) such that:

$$\vec{v} = \vec{\omega} \times \vec{r}(t) \tag{9.3.294}$$

So we have:

$$\vec{a}=\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\mathrm{d}(\vec{\omega}\times\vec{r})}{\mathrm{d}t}=\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}+\vec{\omega}\times\frac{\mathrm{d}\vec{r}}{\mathrm{d}t} \tag{9.3.295}$$

that we also write:

$$\boxed{\vec{a}=\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}+\vec{\omega}\times\frac{\mathrm{d}\vec{r}}{\mathrm{d}t}=\vec{a}_{\text{tg}}+\vec{a}_n} \tag{9.3.296}$$

The acceleration of the circular motion is therefore is formed in the general case, of two terms, the first being the "tangential acceleration" always expressing the variation of the speed along the path and the second acceleration perpendicular along the named "normal acceleration" or "centripetal acceleration" (centripetal meaning: "that tends to bring the center"). This is why the normal acceleration is also sometimes denoted by $\vec{a}_c$.

Remark

Following Newton's second law we can associate a force to each of this both acceleration. However there must be no confusion between: "centrifugal force" (Latin for "center fleeing") that describes the tendency of an object following a curved path to fly outwards, away from the center of the curve. It's not really a force as we have already mentioned it plenty of times; it results from inertia — the tendency of an object to resist any change in its state of rest or motion, and the "centripetal force" that is a real force that counteracts the centrifugal force and prevents the object from "flying out," keeping it moving instead with a uniform speed along a circular path.

✍**Examples:**

E1. The centrifugal "force" on Earth's equator is equal to:

$$F_c=m\frac{v^2}{R}=m\frac{(\omega R)^2}{R}=m\omega^2 R=m\cdot(7.292115\cdot 10^{-5})\cdot 6,378,137\cong m\cdot 0.034 \tag{9.3.297}$$

and obviously the tangential force is zero as the tangential acceleration is zero since $\mathrm{d}\omega/\mathrm{d}t=0$! For information the $0.034\,[\mathrm{m}\cdot\mathrm{s}^{-2}]$ is equal to $440.64\,[\mathrm{km}\cdot\mathrm{h}^{-2}]$ (there is a conversion factor of $3,600^2/1,000=12,600$).

To compare at the same place to Earth's gravitational acceleration that is of $a_g\cong 9.800\,[\mathrm{m}\cdot\mathrm{s}^{-2}]$. The resultant is then:

$$a_R=a_g-a_c\cong 9.8-0.034=9.766\,[\mathrm{m}\cdot\mathrm{s}^{-2}] \tag{9.3.298}$$

Interesting result for flat earthers who "believe" that if the Earth was really rotating we should be put in orbit because of the centripetal force....

This is why scientific illiteracy leads ignorant people to not be able to explain the following meme (that is misleading by the way because the face deformation is due to the air speed and not to the the centripetal force) using college level physics:

10 km/h
IG: space.check
100 km/h
1675 km/h

when instead the correct scientific corresponding photomontage is:

20 RPM
60 RPM
0.00069 RPM

E2. We have the angular velocity ω and the orbital radius R for the Earth orbit, we can calculate its centripetal acceleration a using the relation derived earlier above:

$$a_n = \omega^2 r = \left(1.991 \cdot 10^{-7}\right)^2 \cdot \left(1.5 \cdot 10^{11}\right) \cong \left(3.9686321 \cdot 10^{-14}\right) \cdot \left(1.5 \cdot 10^{11}\right) \cong 5.9529 \cdot 10^{-3}\,[\mathrm{m} \cdot \mathrm{s}^{-2}] \tag{9.3.299}$$

For information the $5.9529 \cdot 10^{-3}\,[\mathrm{m} \cdot \mathrm{s}^{-2}]$ is equal to $77.15\,[\mathrm{km} \cdot \mathrm{h}^{-2}]$.

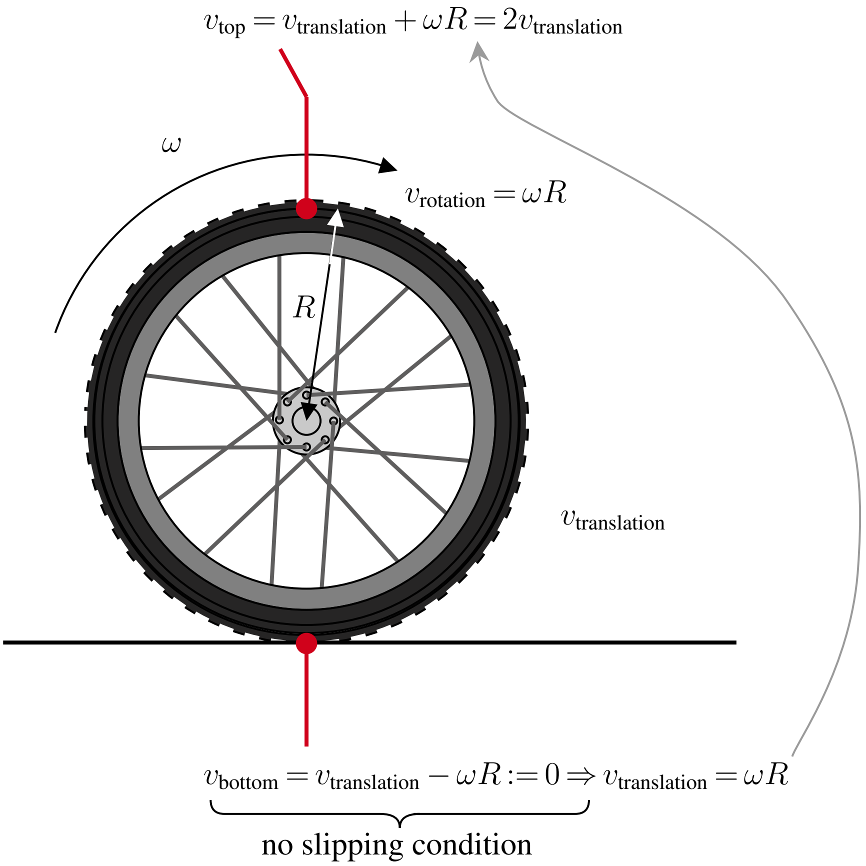
Again the tangential acceleration of the Earth assuming it's on a circular orbit is equal to zero $a_{\text{tg}} = \mathrm{d}\omega/\mathrm{d}t = 0$.

Some sciences prove that everything you know is wrong. Physics doesn't. It just proves that everything you know is relative. A good example of this is the motion of the wheel. Although it was one of humankind's earliest machines, it still has some tricks up its sleeve.

When we measure speed, we generally measure the distance an object goes over time. For an overall car, that's a fine measurement. But the wheels are in different kinds of motion. When a wheel skids, it's moving over the road without any traction. The rubber of the wheel is sliding with respect to the surface of the road. Tires don't usually, or optimally, skid. They aren't usually moving over the ground – at least the part that touches the ground isn't. It's gripping, and staying still.

The car is moving forward at a certain speed, $v_{\text{translational}}$, with respect to the ground. The bottom of the wheel is assumed motionless in respect to the ground. In order for the bottom of the wheel to have a speed of zero when the car is racing forward, it has to be going backwards just as much as the car is going forwards. It's like someone on a moving sidewalk walking backwards as fast as the sidewalk is pushing them forwards, so they don't appear to move when observed from someone off the sidewalk.

Here's where things get weird. The exact center of the wheel moves at the same speed of the car, of course. So looked at from the road, it is moving at speed $v_{\text{translational}}$. But the top of the wheel is moving with the speed of the car, and it is also moving forward at exactly the speed that the bottom of the wheel is moving backward. Since the bottom of the wheel is spinning backwards at negative $v_{\text{translational}}$, so the top of the wheel is spinning forwards at speed positive v_{top}, and also moving with the car at speed positive $v_{\text{translational}}$, making for a combined speed of $2v_{\text{translational}}$.



$v_{\text{top}} = v_{\text{translation}} + \omega R = 2v_{\text{translation}}$
ω
$v_{\text{rotation}} = \omega R$
R
$v_{\text{translation}}$
$\underbrace{v_{\text{bottom}} = v_{\text{translation}} - \omega R := 0}_{\text{no slipping condition}} \Rightarrow v_{\text{translation}} = \omega R$

And that is how a single wheel, all in one piece and attached to a car going at a steady pace can have a measured speed of 0, $v_{\text{translational}}$, and $2v_{\text{translational}}$, all at the same time.

The relation between the velocity at the top, center and bottom of the wheel is geometrical and is not affected by friction per-se. If the car wheel spins with angular frequency ω, has a radius R and velocity at the axle of $v_{\text{translational}}$ then the velocity of the wheel at the top and bottom is:

$$v_{\text{top}} = v_{\text{translational}} + \omega R, v_{\text{bottom}} = v_{\text{translational}} - \omega R \tag{9.3.300}$$

If the no slip condition holds then $v_{\text{bottom}} = 0$, so $v_{\text{translational}} = \omega R$. Using this in the top equation gives $v_{\text{top}} = v_{\text{translational}} + v_{\text{translational}} = 2v_{\text{translational}}$, independent of R! This is because both v and v_{top} increase in the same proportion as R increases.

The reader interested to vector expressions of the speed and acceleration in cartesian, polar, cylindrical and spherical coordinates should refer to the section of Vector Calculus (see page 1846) where all the details are given where we get for recall:

- In cartesian coordinates:
  - Velocity:

$$\vec{v} = \left(\dot{x}(t), \dot{y}(t), \dot{z}(t),\right) \tag{9.3.301}$$

  - Acceleration:

$$\vec{a} = \left(\ddot{x}(t), \ddot{y}(t), \ddot{z}(t), t\right) \tag{9.3.302}$$

- In polar coordinates:
  - Velocity:

$$\vec{v}=\dot{r}\vec{e}_r+\vec{e}_\phi r\dot{\phi} \tag{9.3.303}$$

  - Acceleration:

$$\vec{a}=\vec{e}_r(\ddot{r}-\dot{\phi}^2 r)+\vec{e}_\phi(2\dot{r}\dot{\phi}+r\ddot{\phi}) \tag{9.3.304}$$

- In cylindrical coordinates:
  - Velocity:

$$\vec{v}=\dot{r}\vec{e}_r+\vec{e}_\phi r\dot{\phi}+\vec{e}_z\dot{z} \tag{9.3.305}$$

  - Acceleration:

$$\vec{a}=\vec{e}_r\left(\ddot{r}-r\dot{\phi}^2\right)+\vec{e}_\phi\left(r\ddot{\phi}+2\dot{r}\dot{\phi}\right)+\vec{e}_z\ddot{z} \tag{9.3.306}$$

- In spherical coordinates:
  - Velocity:

$$\vec{v}=\dot{r}\vec{e}_r+\vec{e}_\theta r\dot{\theta}+\vec{e}_\phi r\dot{\phi}\sin(\theta) \tag{9.3.307}$$

  - Acceleration:

$$\begin{aligned}\vec{a}=&\vec{e}_r(\ddot{r}-r\dot{\theta}^2-r\dot{\phi}^2\sin^2(\theta))+\vec{e}_\theta(r\ddot{\theta}+2\dot{r}\dot{\theta}-r\dot{\phi}^2\sin\theta\cos(\theta))\\&+\vec{e}_\phi(r\ddot{\phi}\sin(\theta)+2r\dot{\theta}\dot{\phi}\cos(\theta)+2\dot{r}\dot{\phi}\sin(\theta))\end{aligned} \tag{9.3.308}$$

For the details of the analysis of the velocity and acceleration of a elliptical motion the reader should refer to the section of Astronomy.

Also from the vis-viva equation proved in the section of Aerospace Engineering (see page 8619) we get the speed of a body in any point of an ellipse:

$$v=\sqrt{GM\left(\frac{2}{r(\theta)}-\frac{1}{a}\right)} \tag{9.3.309}$$

where as proved in the section of Analytical Geometry (see page 2785):

$$r(\theta)=\frac{a(1-e^2)}{1+e\cos(\theta)} \tag{9.3.310}$$

where a is the semi-major axis of the ellipse.

For non-planar and not rectilinear motions (that is to say: the generalization of what we have seen so far). The reader should refer to the section of Differential Geometry (see page 2850).

If we express the circular movement of a point P from a system of axes lying in the plane of the trajectory, for simplicity, then the position of the point P is given parametrically by (see section Vector Calculus page 1864):

$$\vec{r}(t)=r\cos(\omega t)\vec{i}+r\sin(\omega t)\vec{j}=r\sin\left(\omega t+\frac{\pi}{2}\right)\vec{i}+r\sin(\omega t)\vec{j} \tag{9.3.311}$$

This shows that the circular movement can be considered as the superposition of two sinusoidal movements phase-shifted of $\pi/2$. But if we write now more generally we could also have:

$$\vec{r}(t)=r_1\sin\left(\omega t+\frac{\pi}{2}\right)\vec{i}+r_2\sin(\omega t)\vec{j} \tag{9.3.312}$$

Or even more general:

$$\vec{r}(t)=r_1\sin\left(\omega t+\varphi\right)\vec{i}+r_2\sin(\omega t)\vec{j} \tag{9.3.313}$$

or more general again:

$$\vec{r}(t)=r_1\sin\left(\omega_x t+\varphi\right)\vec{i}+r_2\sin(\omega_y t)\vec{j} \tag{9.3.314}$$

We get by focusing on the coordinates:

$$\begin{aligned}x&=A\sin(\omega_x t)\\ y&=B\sin(\omega_y t+\varphi)\end{aligned} \tag{9.3.315}$$

by varying the phase difference φ and the ratio ω_x/ω_y we get curves that we name "Lissajous figures":

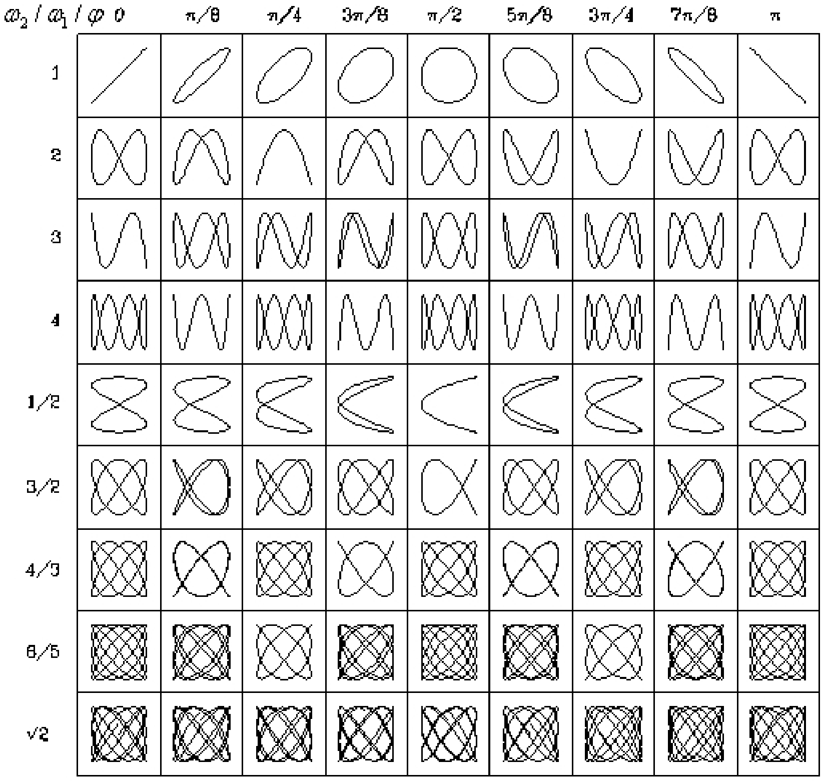


Figure 9.44: Lissajous figures

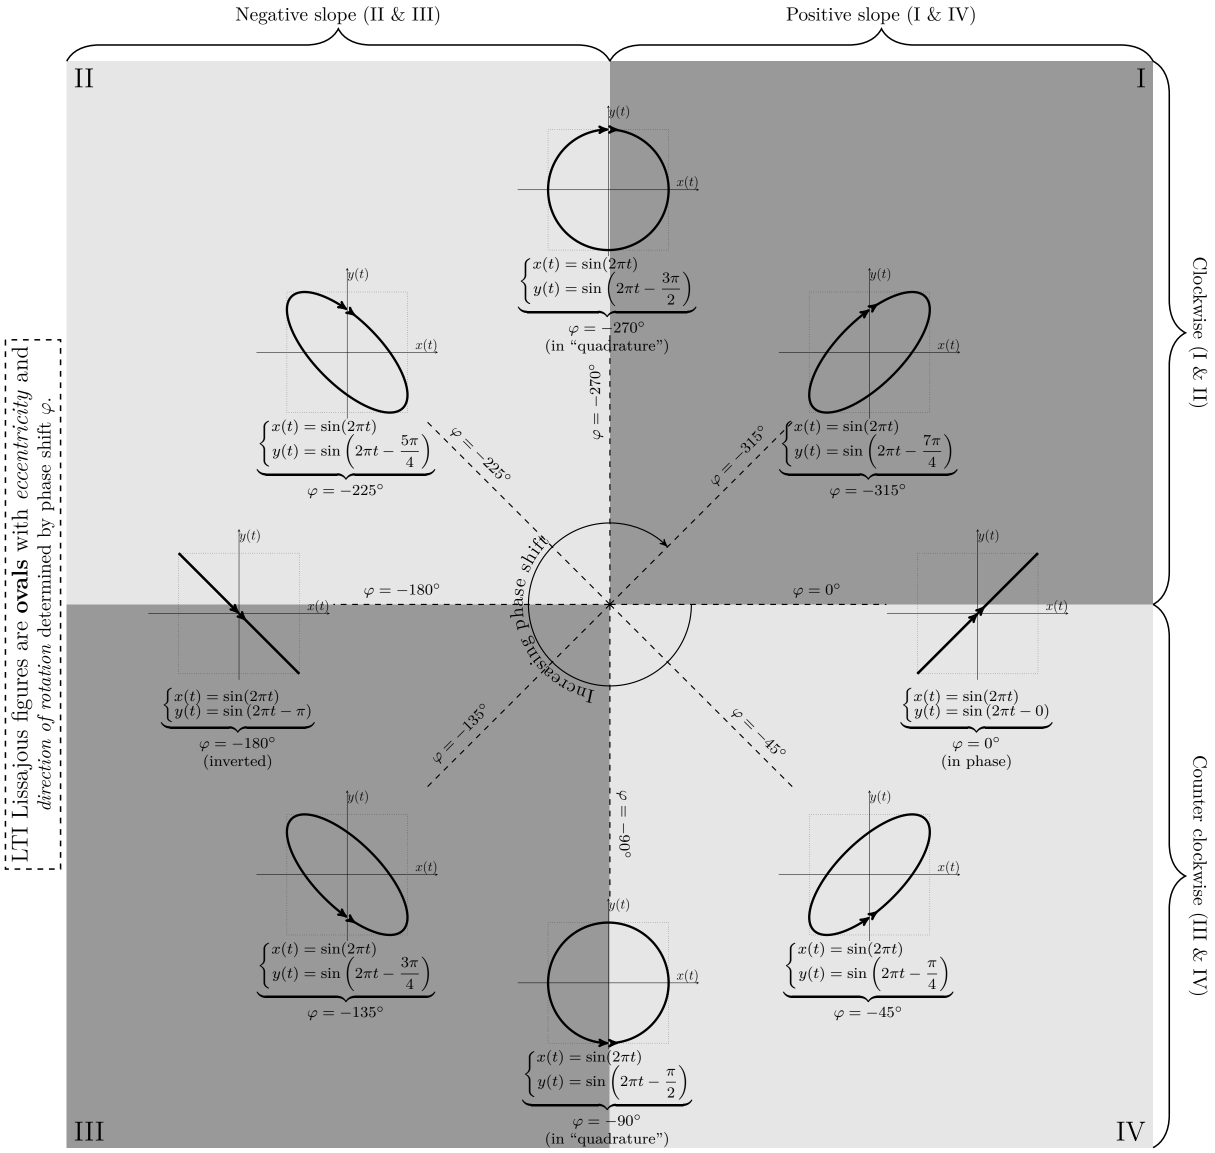
A much more beautiful summary is given by the following illustration:



Negative slope (II & III)
Positive slope (I & IV)
II
I
III
IV
Clockwise (I & II)
Counter clockwise (III & IV)
LTI Lissajous figures are **ovals** with *eccentricity* and *direction of rotation* determined by phase shift φ.
Increasing phase shift
$y(t)$
$x(t)$
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{3\pi}{2}\right)$
$\varphi=-270°$ (in "quadrature")
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{5\pi}{4}\right)$
$\varphi=-225°$
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{7\pi}{4}\right)$
$\varphi=-315°$
$x(t)=\sin(2\pi t)$, $y(t)=\sin(2\pi t-\pi)$
$\varphi=-180°$ (inverted)
$x(t)=\sin(2\pi t)$, $y(t)=\sin(2\pi t-0)$
$\varphi=0°$ (in phase)
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{3\pi}{4}\right)$
$\varphi=-135°$
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{\pi}{4}\right)$
$\varphi=-45°$
$x(t)=\sin(2\pi t)$, $y(t)=\sin\left(2\pi t-\frac{\pi}{2}\right)$
$\varphi=-90°$ (in "quadrature")
$\varphi=-270°$
$\varphi=-225°$
$\varphi=-315°$
$\varphi=-180°$
$\varphi=0°$
$\varphi=-135°$
$\varphi=-45°$
$\varphi=-90°$

Figure 9.45: Several Lissajous figures for different phase delays (author: Krishnatej Vedala, source: Wikipedia)

An important case to consider for the study of circular particles accelerators is the acceleration vector of a uniform circular movement. For such a movement, the position vector in time t is obviously given by:

$$\vec{r}=R\sin(\omega t)\vec{e}_x+R\cos(\omega t)\vec{e}_y \tag{9.3.316}$$

where R is the radius, ω the (constant) angular velocity and $\vec{e}_x$,$\vec{e}_y$ the orthonormal unit vectors for x and y.

The acceleration vector being given by:

$$\vec{a}=\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2} \tag{9.3.317}$$

Carrying out the two derivations we find:

$$\vec{a}=-\omega^2\left[R\sin(\omega t)\vec{e}_x+R\cos(\omega t)\vec{e}_y\right] \tag{9.3.318}$$

Therefore we get for the "centrifugal acceleration":

$$\boxed{\vec{a} = -\omega^2 \vec{r}} \tag{9.3.319}$$

So in uniform circular motion the only acceleration vector always points opposite to the position vector, to the center of the trajectory.

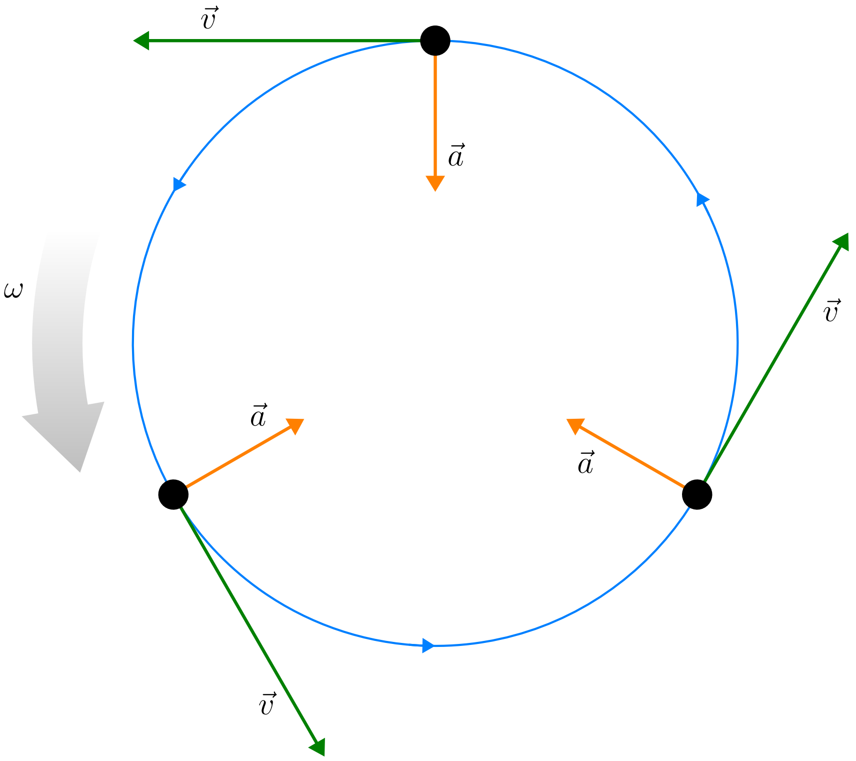


Figure 9.46: Centrifugal acceleration

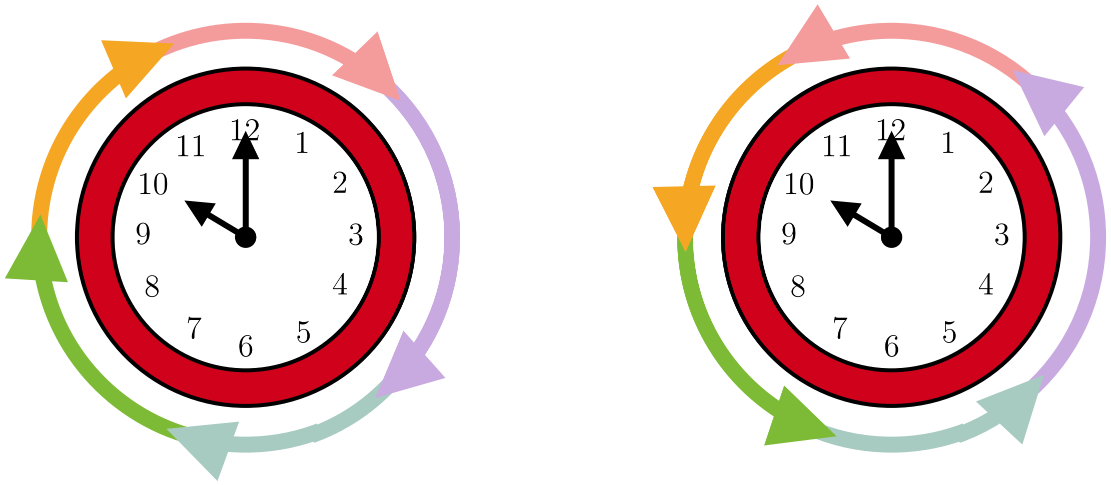
The reader will find very important practical applications of the kinematics of the circular motion to for the industry relatively to mechanics in the section of Mechanical Engineering (see chapter Engineering page 8359) and also to Astronomy (see chapter Cosmology page 5212) and finally to Corpuscular Quantum Physics (see chapter Atomistic page 4616).



These arrows show
clockwise direction

These arrows show
anticlockwise direction

Clockwise is the same direction the
hands of a clock move

(for an observer inside the watch the hands go from left to right)

(for an observer outside the watch the hands go from right to left)

Anticlockwise (or "counter-clockwise"/"trigonometric")
is the opposite direction to the hands of a clock move

(for an observer inside the watch the hands go from right to left)

(for an observer outside the watch the hands go from left to right)

The rotation is observer dependant!
(that's why the stars appear to rotate anticlockwise in northern hemisphere
and clockwise in the southern hemisphere)

Figure 9.47: **Reminder of typical rotation descriptions**

9.3.8 Energy, Work and Power

When a force acts upon an object to cause a displacement of the object, it is said that work was done upon the object. There are three key ingredients to work - force, displacement, and cause. In order for a force to qualify as having done work on an object, there must be a displacement and the force must cause the displacement. There are several good examples of work that can be observed in everyday life - a horse pulling a plow through the field, a father pushing a grocery cart down the aisle of a grocery store, a freshman lifting a backpack full of books upon her shoulder, a weightlifter lifting a barbell above his head, an Olympian launching the shot-put, etc. In each case described here there is a force exerted upon an object to cause that object to be displaced.

If a mass point m undergoes an elementary displacement $\mathrm{d}\vec{r}$ under the effect of a force $\vec{F}$, this force performs an elementary work W given by definition by the "work equation":

$$\boxed{\mathrm{d}W=\vec{F}\circ\mathrm{d}\vec{r}=\|\vec{F}\|\cdot||\mathrm{d}\vec{r}\|\cos(\alpha)} \qquad (9.3.320)$$

However the reader must be careful. It's now why a body accelerates (begin to move) that there is necessarily a force!!! Indeed, Einstein has proved that what we have consider for centuries as the "gravitational force" was in fact only a body following the space-time curvature. So never go too quick in conclusion when making science...

On occasion, a force acts upon a moving object to hinder a displacement. Examples might include a car skidding to a stop on a roadway surface or a baseball runner sliding to a stop on the infield dirt. In such instances, the force acts in the direction opposite the objects motion in order to slow it down. The force doesn't cause the displacement but rather hinders it. The negative work refers obviously to the numerical value that results when values of F, d and θ are substituted into the work equation. Since the force vector is directly opposite the displacement vector, theta is π degrees. The $\cos(\pi)$ is -1 and so a negative value results for the amount of work done upon the object.

Definition (#9.3.441): If the work W is positive the work is named "engine work". If negative we speak then of "resistive work".

If the mass m moves from a point A to place B, the total work is:

$$\Delta W=W_{A,B}=\int\limits_A^B\vec{F}\circ\mathrm{d}\vec{r}=\int\limits_A^B\|\vec{F}\|\cos(\alpha)||\mathrm{d}\vec{r}\| \qquad (9.3.321)$$

For the units, we have the option of expressing them in "Joules [J]" or in Newton-meters:

$$[\mathrm{N}\cdot\mathrm{m}]=[\mathrm{J}] \qquad (9.3.322)$$

From the definition above we can also quickly deduce the work of a moment of force (or in other words, the work of a force in a rotational movement) because of an infinitesimal element of movement, we have:

$$\mathrm{d}W=(\vec{F}\times\vec{r})\circ\mathrm{d}\vec{\theta}=(\vec{F}\times\vec{r})\circ\vec{n}\mathrm{d}\theta=\vec{M}\circ\vec{n}\mathrm{d}\theta \qquad (9.3.323)$$

So in the case of circular motion the work of a moment of force will be given by:

$$\boxed{\Delta W = W_{A,B} = \int\limits_{\theta_A}^{\theta_B} = \vec{M} \circ \vec{n} \mathrm{d}\theta} \tag{9.3.324}$$

9.3.8.1 Conservative vector field

If the force $\vec{F}$ is constant in magnitude and in direction (gravity near the Earth's surface for example), the integral calculation of W takes a simpler form:

$$\Delta W = \int\limits_{A}^{B} \vec{F} \circ \mathrm{d}\vec{r} = \vec{F} \circ \int\limits_{A}^{B} \mathrm{d}\vec{r} = \vec{F} \circ (\vec{r}_B - \vec{r}_A) \tag{9.3.325}$$

This result shows that the work depends only the initial and final positions and not of the path travelled in this special condition.

But in fact there is a more general result that we have already proved in the section of Differential and Integral Calculus that is the "fundamental theorem for line integrals" or "gradient theorem for line integrals" that gives us:

$$\boxed{\int\limits_{\Gamma} \vec{F} \circ \mathrm{d}\vec{r} \Leftrightarrow \int\limits_{\Gamma} \vec{\nabla}(U) \circ \mathrm{d}\vec{r} : \quad \int\limits_{\Gamma} \vec{\nabla}(U) \circ \mathrm{d}\vec{r} = U(b) - U(a)} \tag{9.3.326}$$

where $\vec{\nabla}()$ is the gradient operator (see section Vector Calculus page 1869).

The force of gravity, of electrostatic force is a special case of this type but in fact in all situations as it derives from a potential (see details further below)!

A "conservative vector field" (also named a "path-independent vector field") is a vector field $\vec{F}$ whose line integral $\oint_{\Gamma} \vec{F} \circ \mathrm{d}\vec{r}$ over any curve Γ depends only on the endpoints of Γ. Therefore a vector field for which we have:

$$\oint_{\Gamma} \vec{F} \circ \mathrm{d}\vec{r} = 0 \tag{9.3.327}$$

is by definition automatically a conservative vector field and then we say that there is "no circulation around a closed curve".

We have also proved in the section of Vector Calculus the Stokes theorem (see page 1889) that gives for recall a simply connected domain, a continuously differentiable vector field $\vec{F}$:

$$\boxed{\oint \vec{F} \circ \mathrm{d}\vec{r} = \int\limits_{S} \left(\vec{\nabla} \times \vec{F} \right) \circ \mathrm{d}\vec{S}} \tag{9.3.328}$$

Therefore for a conservative vector field:

$$\oint_{\Gamma} \vec{F} \circ \mathrm{d}\vec{r} = \int\limits_{S} \left(\vec{\nabla} \times \vec{F} \right) \circ \mathrm{d}\vec{S} = 0 \Leftrightarrow \vec{\nabla} \times \vec{F} = \vec{0} \tag{9.3.329}$$

So a vector field that is continuously differentiable on a simply connected domain such that:

$$\vec{\nabla}\times\vec{F}=\vec{0} \tag{9.3.330}$$

is also a possible criteria of identification of a conservative vector field.

✍**Example:**

Our goal is to determine if the vector field:

$$\vec{F}=\begin{pmatrix}-\dfrac{y}{x^2+y^2}\\ \dfrac{x}{x^2+y^2}\\ 0\end{pmatrix} \tag{9.3.331}$$

is conservative or not.

One condition for path independence is as we know the following: for a simply connected domain, a continuously differentiable vector field $\vec{f}$ is path-independent if and only if its curl is zero.

Then we have:

$$\vec{\nabla}\times\vec{F}=\begin{pmatrix}\dfrac{\partial}{\partial x}\\ \dfrac{\partial}{\partial y}\\ \dfrac{\partial}{\partial z}\end{pmatrix}\begin{pmatrix}-\dfrac{y}{x^2+y^2}\\ \dfrac{x}{x^2+y^2}\\ 0\end{pmatrix}=\begin{pmatrix}0\\ 0\\ \dfrac{\partial}{\partial x}\left(\dfrac{x}{x^2+y^2}\right)-\dfrac{\partial}{\partial y}\left(-\dfrac{y}{x^2+y^2}\right)\end{pmatrix} \tag{9.3.332}$$

We calculate:

$$\begin{aligned}\frac{\partial F_2}{\partial x}&=\frac{1}{x^2+y^2}-\frac{x(2x)}{(x^2+y^2)^2}=\frac{y^2-x^2}{(x^2+y^2)^2}\\ \frac{\partial F_1}{\partial y}&=-\frac{1}{x^2+y^2}+\frac{y(2y)}{(x^2+y^2)^2}=\frac{y^2-x^2}{(x^2+y^2)^2}\end{aligned} \tag{9.3.333}$$

Since these partial derivatives are equal, the curl is zero.

Can we conclude $\vec{F}$ is conservative? The problem is that $\vec{F}$ is not defined at the origin $(0,0)$. Its domain of definition has a hole in it, which for two-dimensional regions, is enough to prevent it from being simply connected. The test does not apply, and we still don't know whether or not $\vec{F}$ is conservative.

Let's try another test, this time a test for path-dependence. If we can find a closed curve along which the integral of $\vec{F}$ is non-zero, then we can conclude that $\vec{F}$ is path-dependent. If the curve does not go around the origin, then we can use Green's theorem (see section Vector Calculus page 1890) as we have only the third component of the curl that was non-null above:

$$\oint\limits_{\Gamma}(f_x\mathrm{d}x+f_y\mathrm{d}y)=\int_S\left(\frac{\partial f_y}{\partial x}-\frac{\partial f_x}{\partial y}\right)\mathrm{d}S_z \tag{9.3.334}$$

to show the integral of $\vec{F}$ is zero or not using path integral rather than directly the curl.

We choose for closed path a circle and then we can use a re-parametrization of the field using $x=\cos(t)$ and $y=\sin(t)$ with $0\leq t\leq 2\pi$. Then on the unit circle, $\vec{F}$ takes a simple form:

$$\vec{F}=\left(\frac{-\sin(t)}{\cos^2(t)+\sin^2(t)},\frac{\cos(t)}{\cos^2(t)+\sin^2(t)}\right)=(-\sin(t),\cos(t)) \tag{9.3.335}$$

and we have obviously:

$$\begin{aligned}x=\cos(t)&\Rightarrow \mathrm{d}x=-\sin(t)\mathrm{d}t\\ y=\sin(t)&\Rightarrow \mathrm{d}y-\cos(t)\mathrm{d}t\end{aligned} \tag{9.3.336}$$

Therefore:

$$\begin{aligned}\oint_\Gamma \vec{F}\circ\mathrm{d}\vec{r}&=\int_a^b\begin{pmatrix}F_1\\F_2\end{pmatrix}\circ\begin{pmatrix}\mathrm{d}x\\ \mathrm{d}y\end{pmatrix}\mathrm{d}t=\int_0^{2\pi}\begin{pmatrix}-\sin(t)\\ \cos(t)\end{pmatrix}\circ\begin{pmatrix}-\sin(t)\\ \cos(t)\end{pmatrix}\mathrm{d}t\\ &=\int_0^{2\pi}\left(\sin^2(t)+\cos^2(t)\right)\mathrm{d}t=\int_0^{2\pi}1\mathrm{d}t=2\pi\end{aligned} \tag{9.3.337}$$

The hole in the domain at the origin did end up causing trouble. We found a curve Γ where the circulation around Γ is not zero. The vector field $\vec{F}$ is therefore path-dependent.

The relation:

$$\Delta W=E_c(B)-E_c(A) \tag{9.3.338}$$

is sometimes named "theorem of kinetic energy" or "work-energy theorem".

Note that in the case of a rectilinear movement, to which a mobile initially at rest travels a distance d distance being subjected to a certain force, we have (omitting of course the change in potential energy and energy loss by friction):

$$W=Fd=\frac{1}{2}mv^2\Leftrightarrow F=\frac{mv^2}{2d} \tag{9.3.339}$$

that we name "working force".

9.3.8.2 Kinetic Energy

Newton's second law $\vec{F}=m\vec{a}$ applies along a path A-B. By using the expression of the work we have:

$$\Delta W=\int\limits_A^B \vec{F}\circ\mathrm{d}\vec{r}=\int\limits_A^B m\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}\circ\mathrm{d}\vec{r}=\int\limits_A^B m\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}\circ\vec{v}\mathrm{d}t=m\int\limits_A^B \vec{v}\circ\mathrm{d}\vec{v} \tag{9.3.340}$$

and by developing the dot product using the components we have:

$$\Delta W=m\int\limits_A^B (v_x\mathrm{d}v_x+v_y\mathrm{d}v_y+v_z\mathrm{d}v_z)=\frac{1}{2}m(v_x^2+v_y^2+v_z^2)\Big|_A^B=\frac{1}{2}mv_B^2-\frac{1}{2}mv_A^2 \tag{9.3.341}$$

By definition we say that each term in the last equality is the (non-relativistic) "kinetic energy" denoted by:

$$\boxed{E_{\text{cin}}=E_c=\frac{1}{2}mv^2} \tag{9.3.342}$$

and it is measured obviously also in Joules [J] (or other exotic derivate units whose theoretical physicists sometimes abuse a little bit too much...) and is always positive in mechanics or any other field of physics.

The previous development can then be rewritten as:

$$\Delta W=m\int\limits_A^B (v_x\mathrm{d}v_x+v_y\mathrm{d}v_y+v_z\mathrm{d}v_z)=\frac{1}{2}mv_B^2-\frac{1}{2}v_A^2=E_c(B)-E_c(A) \tag{9.3.343}$$

Therefore when a body moves (without rotation on itself) under the action of any force $\vec{F}$, the work of this acceleration force on any path A, B is equal to the change in kinetic energy of the body.

9.3.8.2.1 Moment of inertia

The "moment of inertia", otherwise known as the "angular mass" or "rotational inertia", of a rigid body determines the torque needed for a desired angular acceleration about a rotational axis. It depends on the body's mass distribution and the axis chosen, with larger moments requiring more torque to change the body's rotation.

For bodies constrained to rotate in a plane, we will see that is sufficient to consider their moment of inertia about an axis perpendicular to the plane. For bodies free to rotate in three dimensions, their moments must be described by a symmetric 3×3 matrix; each body has a set of mutually perpendicular principal axes for which this matrix is diagonal and torques around the axes act independently of each other.

To a rigid solid rotating about an axis at the angular velocity $\vec{\omega}$, the elementary kinetic energy of any point of mass $\mathrm{d}m$, located off-axis, is:

$$\mathrm{d}E_c=\frac{1}{2}v^2\mathrm{d}m=\frac{1}{2}\mathrm{d}m=\frac{1}{2}\left(\vec{\omega}\times\vec{r}\right)^2\mathrm{d}m=\frac{1}{2}(\omega r\sin(\alpha))^2\mathrm{d}m=\frac{1}{2}(\omega r)^2\mathrm{d}m \tag{9.3.344}$$

since $\vec{\omega}$ and $\vec{r}$ are perpendicular. The total kinetic energy is then:

$$E_c = \int \mathrm{d}E_c = \frac{1}{2}\omega^2 \int r^2 \mathrm{d}m \tag{9.3.345}$$

We have become accustomed in physics to write this last relation:

$$\boxed{E_c = \frac{1}{2}\omega^2 \int r^2 \mathrm{d}m = \frac{1}{2}\omega^2 J} \tag{9.3.346}$$

with the "moment of inertia" defined by:

$$J = \int r^2 \mathrm{d}m \tag{9.3.347}$$

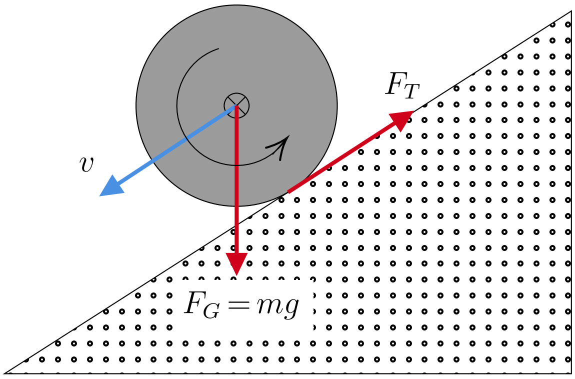
Examples:

E1. Let us calculate the final velocity of a rigid ball falling on an inclined rigid plane with non-zero friction (therefore the ball is going to rotate) in a gravitational potential field where the friction heat can be neglected and in vacuum.

The answer of the beginner will often be obtained by considering only the kinetic energy but not the rotating speed of the ball. Now we must take this into account through its moment of inertia.

So we have the total kinetic energy that the translation kinetic energy of the center of mass plus the rotational energy around the same center of mass:

$$E_c = E_{\text{transl.}} + E_{\text{rot.}} = \frac{1}{2}mv_G^2 + \frac{1}{2}J_G\omega^2 = \frac{1}{2}v_G^2\left(m + \frac{J}{r^2}\right) \tag{9.3.348}$$



equating that value with that of the gravitational potential energy (see further below), assuming a zero initial velocity of fall, we have:

$$\Delta E_c = \Delta E_p \Leftrightarrow mgh = \frac{1}{2}v_G^2\left(m + \frac{J_G}{r^2}\right) \tag{9.3.349}$$

Thus we get the velocity acquired at the bottom of the plane (rolling friction not included...):

$$v_G=\sqrt{\frac{2gh}{1+\dfrac{J_G}{mr^2}}} \tag{9.3.350}$$

and we have proved in the section of Geometric Shapes (see page 2886) that the moment of inertia of a solid ball around its center of mass is:

$$J_G=\frac{2}{5}mr^2 \tag{9.3.351}$$

Therefore it comes:

$$v_G=\sqrt{\frac{2gh}{1+\dfrac{2}{5}}}=\sqrt{\frac{5}{7}2gh}=\sqrt{\frac{10}{7}gh} \tag{9.3.352}$$

We see in the special case of the ball, that final speed of drop is (without air friction and without energy loss due to friction) independent of its mass and radius and of then angle of the plane (whether the ball is empty or full) which is relatively counter-intuitive.

E2. A second famous example is the calculation of the rotational kinetic energy of a perfectly spherical planet of homogeneous mass and constant rotational period. Then we have:

$$\begin{aligned}E_c&=\frac{1}{2}\omega^2J=\frac{1}{2}\omega^2\left(\frac{2}{5}MR^2\right)=\frac{2}{10}\omega^2MR^2=\frac{1}{5}\left(\frac{v}{R}\right)^2MR^2=\frac{1}{5}v^2M\\&=\frac{1}{5}v^2(\rho V)=\frac{1}{5}v^2\left(\rho\frac{4}{3}\pi R^3\right)=\frac{4\pi}{15}\rho R^3v^2=\frac{4\pi}{15}\rho R^2\left(\frac{2\pi R}{T}\right)^2=\frac{16\pi^3}{15}\rho\frac{R^5}{T^2}\end{aligned} \tag{9.3.353}$$

In a solid, the distribution of the material about an axis will obviously be different depending on the chosen axis. The moment of inertia corresponding will also be obviously different. It is therefore essential to specify the axis with respect to which we wish to determine the moment of inertia. We see that in practice that engineers often place the axis so that it passes through the center of mass. In the tables, we frequently find expressions of inertia moments of common forms (along a given axis) such as cylinder, cone, sphere, bar, tube.

Here is a summary of some moment of inertia of plane figures among all those proved in detail in the section of Geometric Shapes (see page 2886):

Shape	Figure	Area moment of inertia
Rectangular area		$I_x = \frac{ab^3}{3}$ $I_g = \frac{ab^3}{12}$ $J = \frac{ab}{12}(a^2+b^2)$
Triangular area	 b x_1 y h $\overline{x}$ G $\overline{y}$ x a	$I_x = \frac{ah^3}{12}$ $I_g = \frac{ah^3}{36}$ $I_g = \frac{ah^3}{4}$
Quarter circular area	 y r $\overline{x}$ G $\overline{y}$ x	$I_x = I_y = \frac{\pi r^4}{16}$ $J = \frac{\pi r^4}{8}$
Area of circular sector	 y r α G x α $\overline{x}$	$I_x = \frac{r^4}{4}\left(\alpha - \frac{1}{2}\sin(2\alpha)\right)$ $I_y = \frac{r^4}{4}\left(\alpha + \frac{1}{2}\sin(2\alpha)\right)$ $J = \frac{1}{2}r^4\alpha$
Area of elliptical quadrant	 y $\overline{x}$ G b $\overline{y}$ x a	$I_x = \frac{\pi ab^3}{16}$ $I_y = \frac{\pi a^3 b}{16}$ $J = \frac{\pi ab}{16}(a^2+b^2)$

Figure 9.48: **Summary Moment of inertia of some planar shapes**

and same for some body (volumetric) shapes (proofs are also available in the same section of Geometric Shapes at page 2886):

Body	Figure	Moments of inertia
Rectangular Parallelepiped		$I_{xx}=\frac{1}{12}m\left(a^2+l^2\right)$ $I_{yy}=\frac{1}{12}m\left(b^2+l^2\right)$ $I_{zz}=\frac{1}{12}m\left(a^2+b^2\right)$ $I_{y_1y_1}=\frac{1}{12}mb^2+\frac{1}{3}ml^2$
Circular Cylinder		$I_{xx}=\frac{1}{4}mr^2+\frac{1}{12}ml^2$ $I_{x_1x_1}=\frac{1}{4}mr^2+\frac{1}{3}ml^2$ $I_{zz}=\frac{1}{2}mr^2$
Semicylinder		$I_{xx}=I_{yy}=\frac{1}{4}mr^2+\frac{1}{12}ml^2$ $I_{x_1x_1}=I_{y_1y_1}=\frac{1}{4}mr^2+\frac{1}{3}ml^2$ $I_{zz}=\frac{1}{2}mr^2$
Circular Cylindrical shell		$I_{xx}=\frac{1}{2}mr^2+\frac{1}{12}ml^2$ $I_{x_1x_1}=\frac{1}{2}mr^2+\frac{1}{3}ml^2$ $I_{zz}=mr^2$
Half Cylindrical shell		$I_{xx}=I_{yy}=\frac{1}{2}mr^2+\frac{1}{12}ml^2$ $I_{x_1x_1}=I_{y_1y_1}=\frac{1}{2}mr^2+\frac{1}{3}ml^2$ $I_{zz}=mr^2$
Sphere		$I_{zz}=\frac{2}{5}mr^2$
Spherical shell		$I_{zz}=\frac{2}{3}mr^2$
Hemisphere		$I_{xx}=I_{yy}=I_{zz}=\frac{2}{5}mr^2$
Hemispherical Shell		$I_{xx}=I_{yy}=I_{zz}=\frac{2}{3}mr^2$

Figure 9.49: Summary of very common bodies moments of inertia

We saw in our study of angular momentum that:

$$\vec{b}=mr^2\vec{\omega} \tag{9.3.354}$$

and just before that the moment of inertia is given by:

$$J=\int r^2\mathrm{d}m \tag{9.3.355}$$

So we have:

$$\mathrm{d}\vec{b}=r^2\vec{\omega}\mathrm{d}m \tag{9.3.356}$$

hence:

$$\vec{b}=\vec{\omega}\int r^2\mathrm{d}m \tag{9.3.357}$$

We finally get:

$$\boxed{\vec{b}=J\vec{\omega}} \tag{9.3.358}$$

That it is the expression of the angular momentum of a rigid body rotating on itself (on one of its possible axes of rotation) commonly named "spin angular moment".

As we showed during our study of the angular momentum:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\vec{r}\times\vec{F}=\vec{M} \tag{9.3.359}$$

then it comes under the assumption that the mass and geometry of the solid remain constant ... that the moment of force is then:

$$\boxed{\vec{M}=\frac{\mathrm{d}}{\mathrm{d}t}(J\vec{\omega})=J\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}} \tag{9.3.360}$$

And obviously, if we study a system in which the angular momentum is conservative, it is obvious that:

$$\boxed{\vec{M}=\vec{0}\Rightarrow\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=\vec{0}\Rightarrow\vec{b}=c^{te}=J\vec{\omega}} \tag{9.3.361}$$

This conservation of angular momentum is applicable in a multitude of experiences as the well known which is to turn on a chair and spread out hands or legs which will decrease the speed (and vice versa) as illustrated in figure below:

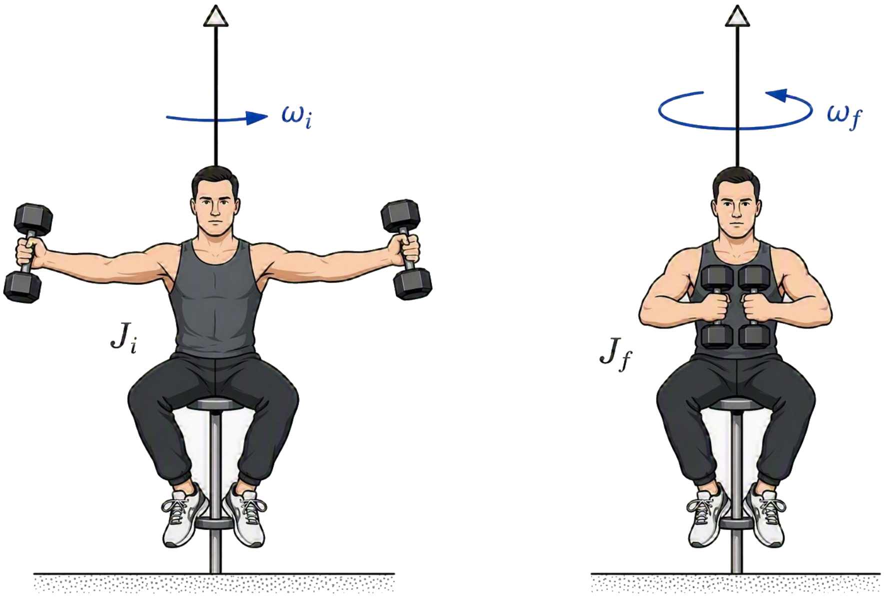


Figure 9.50: **Conservation of the angular momentum on variation of inertia momentum**

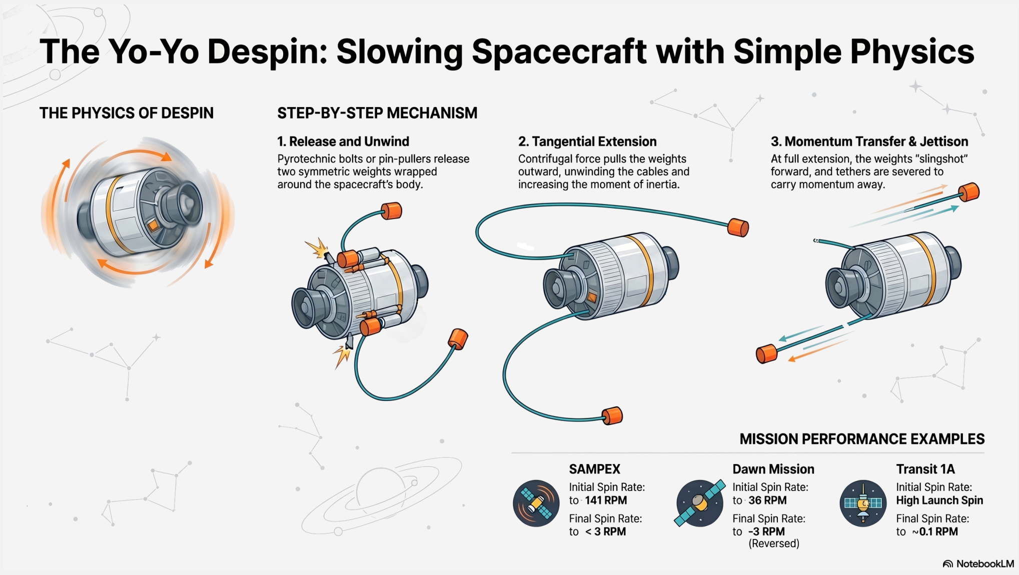
In figure skating and pole dance, the concept of angular momentum is extremely important in order to complete a successful figure, without it there would be no nice spinning effect at all!

Remark

A technique named the "yo-yo despin effect" reduces an spacecraft's rotation by exploiting moment of inertia following the idea just seen above. Two small masses attached to cables are released and swing outward as the spacecraft spins; when the masses move farther from the rotation axis, the system's moment of inertia increases, and—because angular momentum must stay constant—the rotation rate decreases. Once the spin slows to the desired level, the cables can be jettisoned, leaving the spacecraft stabilized without needing continuous propulsion.



The Yo-Yo Despin: Slowing Spacecraft with Simple Physics

THE PHYSICS OF DESPIN

STEP-BY-STEP MECHANISM

1. Release and Unwind
Pyrotechnic bolts or pin-pullers release two symmetric weights wrapped around the spacecraft's body.

2. Tangential Extension
Contrifugal force pulls the weights outward, unwinding the cables and increasing the moment of inertia.

3. Momentum Transfer & Jettison
At full extension, the weights "slingshot" forward, and tethers are severed to carry momentum away.

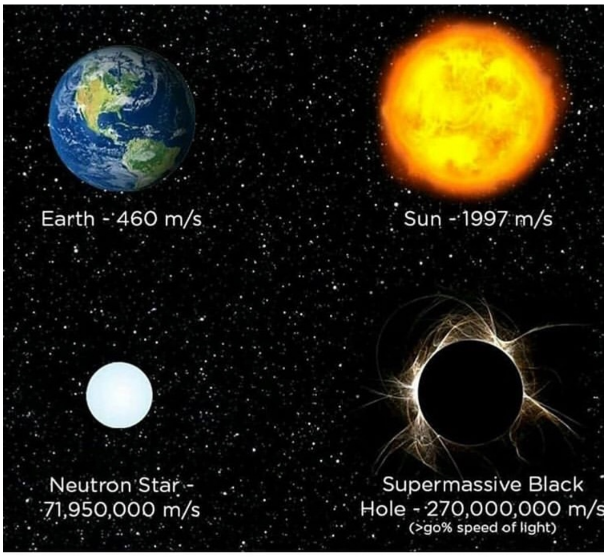
MISSION PERFORMANCE EXAMPLES

SAMPEX
Initial Spin Rate:
to **141 RPM**
Final Spin Rate:
to **< 3 RPM**

Dawn Mission
Initial Spin Rate:
to **36 RPM**
Final Spin Rate:
to **−3 RPM**
(Reversed)

Transit 1A
Initial Spin Rate:
High Launch Spin
Final Spin Rate:
to **~0.1 RPM**

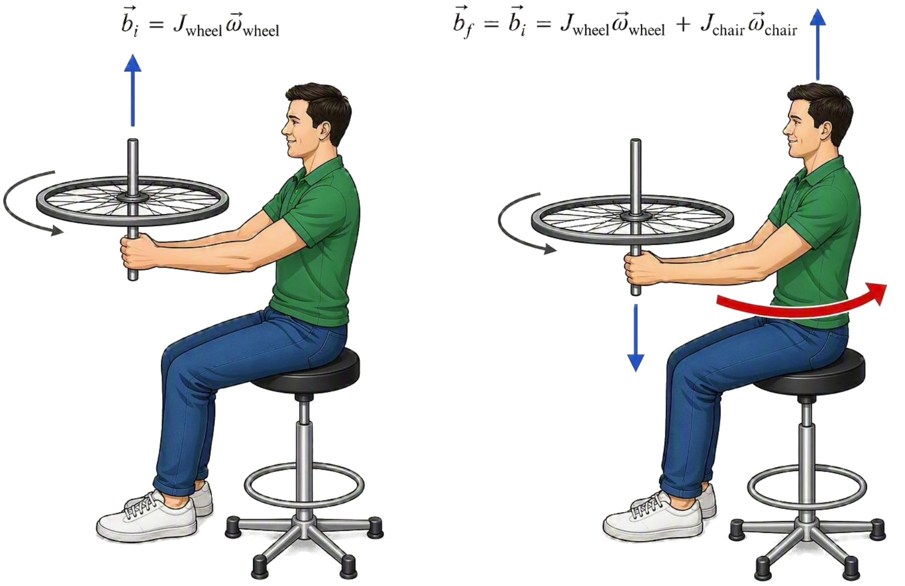
Apart for the Earth that rotates on itself, the Sun (actually a G2V-type star, aka yellow dwarf) rotates on itself also (as most stars do!). But when a star collapse into a neutron star or even into a Black Hole, most of the angular momentum is conserved and therefore the spin rotation increase drastically:



Earth - 460 m/s
Sun - 1997 m/s
Neutron Star - 71,950,000 m/s
Supermassive Black Hole - 270,000,000 m/s
(>90% speed of light)

Figure 9.51: How fast does it spin at equator?

Another curious experience (but mathematically correct) to take place ourselves on a turntable with a wheel in rotation held horizontally (vertical angular momentum is zero) and put it then vertically (same type of experiment can be done in the opposite direction). As the vertical momentum must remain zero to counteract this (or must remain constant in direction and in amplitude as it is a vectorial quantity), the plateau on which is put the experimenter will rotate in the opposite direction of rotation of the wheel.



$\vec{b}_i = J_{\text{wheel}}\vec{\omega}_{\text{wheel}}$
$\vec{b}_f = \vec{b}_i = J_{\text{wheel}}\vec{\omega}_{\text{wheel}} + J_{\text{chair}}\vec{\omega}_{\text{chair}}$

Figure 9.52: Conservation of total angular momentum by variation of intern angular momentum

Remarks

R1. The movement of large masses on the surface of the Earth (icebergs, river flooding, tectonic plates, etc.) cause changes in moment of inertia of the Earth. It follows therefore fluctuations of the angular velocity and therefore imperfection of astronomical time standard (a few thousandths per day).

R2. A "reaction wheel" (or "momentum wheel") is a type of flywheel used primarily by spacecraft for attitude control without using fuel for rockets or other reaction devices. They are particularly useful when the spacecraft must be rotated by very small amounts, such as keeping a telescope pointed at a star. They may also reduce the mass fraction needed for fuel. This is accomplished by equipping the spacecraft with an electric motor attached to a flywheel which, when its rotation speed is changed, causes the spacecraft to begin to counter-rotate proportionately through conservation of angular momentum. Reaction wheels can rotate a spacecraft only around its center of mass; they are not capable of moving the spacecraft from one place to another.

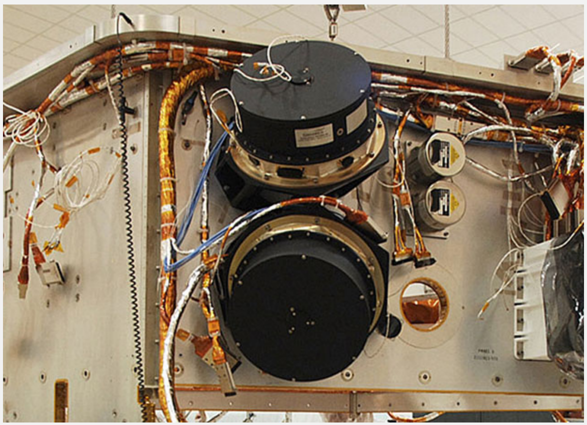


Figure 9.53: **Kepler satellite reaction wheels**

R3. A "control moment gyroscope" is a related but different type of attitude actuator. When mounted to a rigid spacecraft, applying a constant torque to the wheel using one of the gimbal motors causes the spacecraft to develop a constant angular velocity about a perpendicular axis, thus allowing control of the spacecraft's pointing direction. CMGs are generally able to produce larger sustained torques than reaction wheel with less motor heating, and are preferentially used in larger and/or more-agile spacecraft, including Skylab, Mir, and the International Space Station (ISS).

ISS011E11356

Figure 9.54: One of the four, 122 [cm] diameter, ISS control moment gyroscopes (source: NASA)

Now let us come back to the methods of calculation of the moments of inertia. The kinetic energy of a body is the sum of kinetic energy of each element of this body at the macroscopic level, then we have:

$$E_c=\sum_{i=1}^{n} E_{c,i} \tag{9.3.362}$$

Therefore in the context of a solid rigid body rotating around an axis, we have:

$$E_c=\sum_{i=1}^{n} E_{c,i}=\sum_{i=1}^{n}\frac{1}{2}J_i\omega^2=\frac{1}{2}\omega^2\sum_{i=1}^{n} J_i=\frac{1}{2}\omega^2 J \tag{9.3.363}$$

Thus, for a body composed of a plurality of different geometries, the total moment of inertia is the sum of the moments of inertia with respect to the axis of rotation of each of the sub-geometries such that:

$$\sum_{i=1}^{n} J_i=J \tag{9.3.364}$$

When we calculate the moment of a body of inertia relative to a given axis Δ of rotation, it may be interesting to know what is the distance from the axis where we can place fictitiously the whole mass of this body concentrated on a given point for the same moment of inertia. By definition, this distance denoted k and named the "radius of gyration" is trivially given by:

$$\boxed{J_\Delta=Mk^2 \Rightarrow k=\sqrt{\frac{J_\Delta}{M}}} \tag{9.3.365}$$

where J_Δ is the known moment of inertia of the body of mass M relatively to an axis Δ.

By definition, the "polar moment of inertia" (or also "squared moment of inertia") is the moment of inertia defined with respect to a point (a "pole") and not relatively to an axis and written:

$$J_0=\int r^2\mathrm{d}m \tag{9.3.366}$$

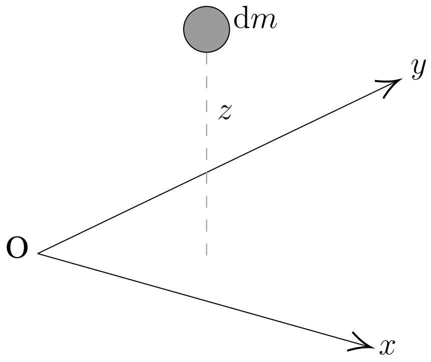
This quantity intervene only for free spins and is of interest, for rotations around a fixed axis, only because it sometimes facilitates the calculation of the axial moments of inertia under the follows relation (in Cartesian coordinates):

$$J_0=\frac{1}{2}(J_x+J_y+J_z) \tag{9.3.367}$$

Proof 9.4.5.

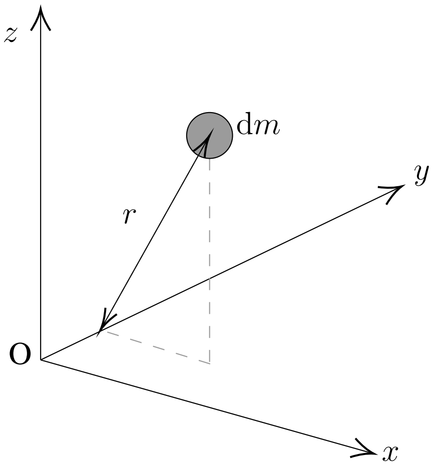
Lemma 9.4.1. The moment of inertia compared to the $x\mathrm{O}y$ plane is trivially given by:

$$J_{x,y}=\int z^2\mathrm{d}m \tag{9.3.368}$$



Lemma 9.4.2. The moment of inertia with respect to an axis is given by:

$$\begin{aligned}J_x&=\int r^2\mathrm{d}m=\int(y^2+z^2)\mathrm{d}m\\J_y&=\int(x^2+z^2)\mathrm{d}m\\J_z&=\int(x^2+y^2)\mathrm{d}m\end{aligned} \tag{9.3.369}$$

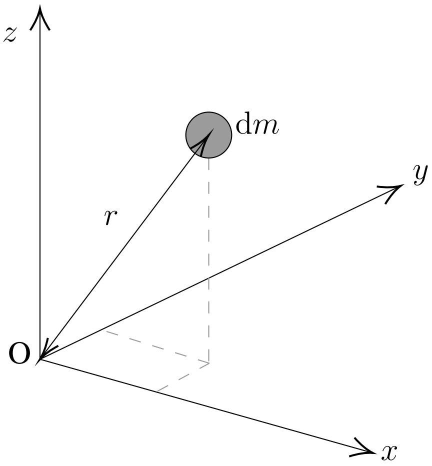


Summing these relations, we deduce:

$$J_x+J_y+J_z=2\int(x^2+y^2+z^2)\mathrm{d}m \tag{9.3.370}$$

The polar moment of inertia is then given by:

$$J_0=\int r^2\mathrm{d}m=\int(x^2+y^2+z^2)\mathrm{d}m \tag{9.3.371}$$



Comparing with the second lemma above we get:

$$\boxed{J_0=\frac{1}{2}(J_x+J_y+J_z)} \tag{9.3.372}$$

■ Q.E.D.

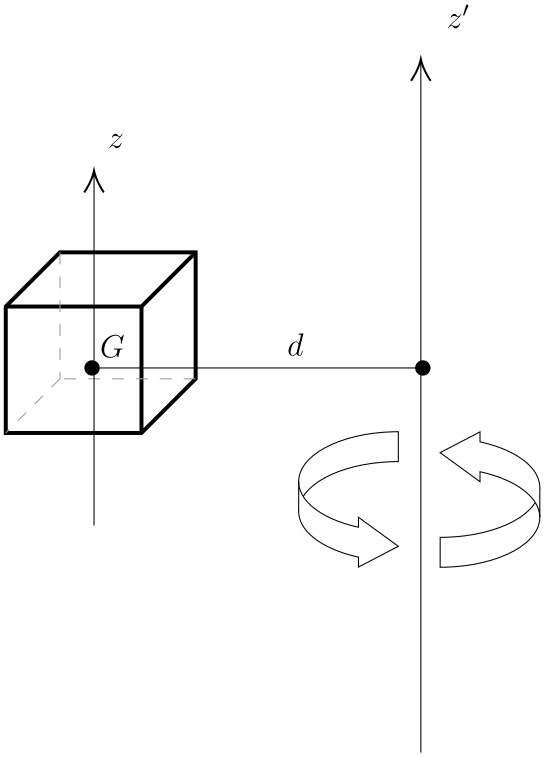
If the body in question has a spherical symmetry, it comes immediately as $J_x=J_y=J_z:=J$ that:

$$J_0=\frac{1}{2}(3J)\Rightarrow J=\frac{3}{2}J_0 \tag{9.3.373}$$

An example is given with the ball (full sphere) in the section on Geometric Shapes in the chapter Geometry (see page 2964).

Suppose now that we know the moment of inertia J_z of a rigid solid body compared to any other perpendicular axis (the chosen axis is not necessarily only assimilated to the common z axis) passing through the center of mass G. Then let us calculate the moment of inertia J_z, relatively to another axis z', parallel to z and remote from distance d, and let us make up appear the existing link between these two different moments of inertia.

So consider the following figure representing our subject of interest:



In a planar Cartesian reference frame, we have for any points (x,y):

$$r^2=x^2+y^2 \tag{9.3.374}$$

and:

$$r'^2=x^2+(y+d)^2 \tag{9.3.375}$$

Then we have:

$$J_z=\int r^2\mathrm{d}m=\int(x^2+y^2)\mathrm{d}m \tag{9.3.376}$$

and:

$$\begin{aligned}J_{z'}&=\int r'^2\mathrm{d}m=\int(x^2+(y+d)^2)\mathrm{d}m=\int(x^2+y^2+2dy+d^2)\mathrm{d}m\\&=\int(x^2+y^2)\mathrm{d}m+\int(2dy+d^2)\mathrm{d}m=J_z+2d\int y\mathrm{d}m+d^2\int\mathrm{d}m=J_z+2d\int y\mathrm{d}m+d^2M\end{aligned} \tag{9.3.377}$$

The term:

$$2d\int y\mathrm{d}m \tag{9.3.378}$$

is zero because if the moment of inertia is calculated relatively to the center mass G as we have assumed it from the beginning, then:

$$y_G=\frac{\displaystyle\int y\mathrm{d}V}{\displaystyle\int \mathrm{d}V}=0 \tag{9.3.379}$$

Ultimately, we finally get the "Huygens-Steiner theorem" also named "parallel axis theorem":

$$\boxed{J_{z'}=J_z+d^2M} \tag{9.3.380}$$

As we will see it in the section on Geometric Shapes in the chapter Geometry (see page 2886), it then becomes easy to calculate the moment of inertia of an equilateral triangle knowing that of a square plate and moving the axis inertia to the point where the triangle is the center of gravity (i.e. at the third of the median between the center of the rectangle and of its vertices).

Since there are as many moments of inertia as axes of rotation and that they are often in practical study cases related to the principal axes of inertia (axis related to the axes of revolution or symmetry planes - see below), it may be useful to introduce a mathematical being useful in the context of representation of moments of inertia which is none other than the "inertia matrix" or also known as (modern formulation) "inertia tensor".

The approach to rigorously determine the expression of this tensor is the following:

Given A_i a given point of a solid, for which we seek to calculate the moment of inertia and Δ the axis of origin O and vector of unit vector $\vec{u}$ relative to which we wish to calculate the moment of inertia. Any point A_i of the solid can be projected (orthogonal projection) on a point $H\in\Delta$ from the knowledge of the angle θ between Δ and $\overrightarrow{\mathrm{O}A_i}$ such that:

$$\overline{HA}=\overline{\mathrm{O}A}\sin(\theta)\Rightarrow\overline{HA}^2=\overline{\mathrm{O}A_i}^2\sin^2(\theta)=||\overrightarrow{\mathrm{O}A_i}\times\vec{u}||^2 \tag{9.3.381}$$

Therefore:

$$J_\Delta=\int r^2\mathrm{d}m=\int||\overrightarrow{\mathrm{O}A_i}\times\vec{u}||^2\mathrm{d}m=\int||\overrightarrow{\mathrm{O}A_i}\times\vec{u}||\cdot||\overrightarrow{\mathrm{O}A_i}\times\vec{u}||\mathrm{d}m=\int(\overrightarrow{\mathrm{O}A_i}\times\vec{u})\circ(\overrightarrow{\mathrm{O}A_i}\times\vec{u})\mathrm{d}m \tag{9.3.382}$$

Based on the properties of the mixed product (see section Vector Calculus page 1838) and of the scalar product:

$$(\vec{x}\times\vec{y})\circ\vec{z}=\vec{x}\circ(\vec{y}\times\vec{z})\qquad\text{and}\qquad(\vec{x}\times\vec{y})\circ\vec{z}=\vec{z}\circ(\vec{x}\times\vec{y}) \tag{9.3.383}$$

we have:

$$(\overrightarrow{\mathrm{O}A_i}\times\vec{u})\circ(\overrightarrow{\mathrm{O}A_i}\times\vec{u})=\vec{w}\circ(\overrightarrow{\mathrm{O}A_i}\times\vec{u})=(\vec{w}\times\overrightarrow{\mathrm{O}A_i})\circ\vec{u}=\vec{u}\circ(\vec{w}\times\overrightarrow{\mathrm{O}A_i})=\vec{u}\circ\left(\left(\overrightarrow{\mathrm{O}A_i}\times\vec{u}\right)\times\overrightarrow{\mathrm{O}A_i}\right) \tag{9.3.384}$$

and therefore:

$$J_\Delta=\int\vec{u}\circ\left(\left(\overrightarrow{\mathrm{O}A_i}\times\vec{u}\right)\times\overrightarrow{\mathrm{O}A_i}\right)\mathrm{d}m \tag{9.3.385}$$

As $\vec{u}$ is a vector of constant direction whatever the point of integration, we can take it out of the integral such that:

$$J_\Delta=\vec{u}\circ\int\left(\left(\overrightarrow{\mathrm{O}A_i}\times\vec{u}\right)\times\overrightarrow{\mathrm{O}A_i}\right)\mathrm{d}m=\vec{u}\circ\vec{v} \tag{9.3.386}$$

We can check that if we replace $\vec{u}$ by $\vec{u}_1+\vec{u}_2$, we will get a result that also sum (of the type $\vec{v}=\vec{v_1}+\vec{v}_2$ that is the sum of two integrals) up by the property of linearity of the cross product (see section Vector Calculus page 1833).

Therefore, the application that to $\vec{u}$ associated a given $\vec{v}$ is therefore a linear application that can be represented in a given basis $\mathcal{B}$ by a matrix:

$$\vec{u}\rightarrow\vec{v}=[J_0]_{\mathcal{B}}\vec{u} \tag{9.3.387}$$

The matrix $[J_0]_{\mathcal{B}}$ is named "inertia tensor" of the system relatively to the point O, in the base $\mathcal{B}$.

The moment of inertia of a system with respect to any axis Δ of unit vector $\vec{u}$ is given by:

$$\boxed{\forall \text{O}\in\Delta:\quad J_{\Delta}=\vec{u}\circ([J_0]_{\mathcal{B}}\vec{u})} \tag{9.3.388}$$

The problem now is to calculate the elements of the tensor $[J_0]$ for a given basis $\mathcal{B}$. Given a reference frame $(\text{O},\vec{i},\vec{j},\vec{k})$ such that $\text{O}\in\Delta$ we put:

$$\vec{u}=\alpha\vec{i}+\beta\vec{j}+\gamma\vec{k} \tag{9.3.389}$$

and:

$$\overrightarrow{\text{O}A}=x\vec{i}+y\vec{j}+z\vec{k} \tag{9.3.390}$$

Using the fact that we know that a cross product can be represented by as an asymmetric matrix operation (see section Vector Calculus page 1831):

$$\overrightarrow{\text{O}A_i}\times\vec{u}=\begin{pmatrix}0 & -z & y\\ z & 0 & -x\\ -y & x & 0\end{pmatrix}\begin{pmatrix}\alpha\\ \beta\\ \gamma\end{pmatrix} \tag{9.3.391}$$

and therefore:

$$\begin{aligned}[J_0]_{\mathcal{B}}\vec{u}&=\int\left(\left(\overrightarrow{\text{O}A_i}\times\vec{u}\right)\times\overrightarrow{\text{O}A_i}\right)=-\int\left(\overrightarrow{\text{O}A_i}\times\left(\overrightarrow{\text{O}A_i}\times\vec{u}\right)\right)\text{d}m\\ &=-\int\begin{pmatrix}-z^2-y^2 & xy & xz\\ xy & -z^2-x^2 & yz\\ xz & yz & -y^2-x^2\end{pmatrix}\begin{pmatrix}\alpha\\ \beta\\ \gamma\end{pmatrix}\text{d}m\\ &=\begin{pmatrix}\int(z^2+y^2)\text{d}m & -\int xy\text{d}m & -\int xz\text{d}m\\ -\int xy\text{d}m & \int(z^2+x^2)\text{d}m & -\int yz\text{d}m\\ -\int xz\text{d}m & -\int yz\text{d}m & \int(y^2+x^2)\text{d}m\end{pmatrix}\begin{pmatrix}\alpha\\ \beta\\ \gamma\end{pmatrix}\end{aligned} \tag{9.3.392}$$

In the above expression of the inertia matrix, we recognize the diagonal elements: it is simply the moments of inertia of the system relatively to the different axes of the base. We name "product of inertia" the non-diagonal elements of the matrix and we write them:

$$J_{xy}=-\int xy\text{d}m\qquad J_{xz}=-\int xz\text{d}m\qquad J_{yz}=-\int yz\text{d}m \tag{9.3.393}$$

Therefore we have:

$$\boxed{J=\begin{pmatrix}J_{\text{O}x} & J_{xy} & J_{xz}\\ J_{xy} & J_{\text{O}y} & J_{yz}\\ J_{xz} & J_{yz} & J_{\text{O}z}\end{pmatrix}=\begin{pmatrix}\int(z^2+y^2)\text{d}m & -\int xy\text{d}m & -\int xz\text{d}m\\ -\int xy\text{d}m & \int(z^2+x^2)\text{d}m & -\int yz\text{d}m\\ -\int xz\text{d}m & -\int yz\text{d}m & \int(y^2+x^2)\text{d}m\end{pmatrix}} \tag{9.3.394}$$

where obviously:

- $J_{\mathrm{O}x}$ is the inertial momentum relatively to $(\mathrm{O},\vec{x})$
- $J_{\mathrm{O}y}$ is the inertial momentum relatively to $(\mathrm{O},\vec{y})$
- $J_{\mathrm{O}z}$ is the inertial momentum relatively to $(\mathrm{O},\vec{z})$
- J_{yz} is the inertial momentum relatively to $(\vec{y},\vec{z})$
- J_{xz} is the inertial momentum relatively to $(\vec{x},\vec{z})$
- J_{xy} is the inertial momentum relatively to $(\vec{x},\vec{y})$

Also sometimes written as (USA notation and mechanical engineers notation):

$$J=\begin{pmatrix} I_{\mathrm{O}x} & I_{xy} & I_{xz} \\ I_{xy} & I_{\mathrm{O}y} & I_{yz} \\ I_{xz} & I_{yz} & I_{\mathrm{O}z} \end{pmatrix}=\begin{pmatrix} I_{xx} & I_{xy} & I_{xz} \\ I_{xy} & I_{yy} & I_{yz} \\ I_{xz} & I_{yz} & I_{zz} \end{pmatrix}=\begin{pmatrix} A & -F & -E \\ -F & B & -D \\ -E & -D & C \end{pmatrix} \tag{9.3.395}$$

If O is assimilated to the center of mass of the solid, we simply write:

$$(J_{\mathrm{O}x},J_{\mathrm{O}y},J_{\mathrm{O}z})=(J_x,J_y,J_z) \tag{9.3.396}$$

It follows if thickness of the study body is negligible compared to the other dimensions then $z=0$ and then we have immediately:

$$J_{xy}=\begin{pmatrix} \int y^2\mathrm{d}m & -\int xy\mathrm{d}m & 0 \\ -\int xy\mathrm{d}m & \int x^2\mathrm{d}m & 0 \\ 0 & 0 & \int(y^2+x^2)\mathrm{d}m \end{pmatrix}=\begin{pmatrix} J_{\mathrm{O}x} & J_{xy} & 0 \\ J_{xy} & J_{\mathrm{O}y} & 0 \\ 0 & 0 & J_{\mathrm{O}z} \end{pmatrix}=\begin{pmatrix} J_{\mathrm{O}x} & J_{xy} & 0 \\ J_{xy} & J_{\mathrm{O}y} & 0 \\ 0 & 0 & J_{\mathrm{O}x}+J_{\mathrm{O}y} \end{pmatrix} \tag{9.3.397}$$

We can also generalize Huygens theorem by making use of this matrix. To do so, let us write (x',y',z') the coordinates of any point A in R' and (x,y,z) its coordinates in R. We write (a,b,c) the coordinates of the O' of R' in R:

$$R\Rightarrow\begin{cases} x'=x-a \\ y'=y-b \\ z'=z-c \end{cases} \tag{9.3.398}$$

as:

$$\overrightarrow{\mathrm{OO}'}+\overrightarrow{\mathrm{O}'A}=\overrightarrow{\mathrm{O}A}\Leftrightarrow\overrightarrow{\mathrm{O}'A}=\overrightarrow{\mathrm{O}A}-\overrightarrow{\mathrm{OO}'} \tag{9.3.399}$$

We then have:

$$\begin{aligned} J_{\mathrm{O}z}&=\int(x^2+y^2)\mathrm{d}m=\int\left((x'+a)^2+(y'+b)^2\right)\mathrm{d}m \\ &=\int(x'^2+y'^2)\mathrm{d}m+2a\int x'\mathrm{d}m+a^2\int\mathrm{d}m+2b\int y'\mathrm{d}m+b^2\int\mathrm{d}m \\ &=J_{\mathrm{O}z'}+M(a^2+b^2)+2a\int x'\mathrm{d}m+2b\int y'\mathrm{d}m \end{aligned} \tag{9.3.400}$$

Now if O' coincides with the center of mass G, then according to the definition of the center of mass:

$$\int \overrightarrow{GA}\mathrm{d}m=\vec{0}\Rightarrow\begin{cases}\int x'\mathrm{d}m=0\\ \int y'\mathrm{d}m=0\\ \int z'\mathrm{d}m=0\end{cases}\tag{9.3.401}$$

We deduce then:

$$J_{\mathrm{O}z}=J_{\mathrm{G}z'}+M(a^2+b^2)\tag{9.3.402}$$

and also:

$$J_{\mathrm{O}x}=J_{\mathrm{G}x'}+M(b^2+c^2)\qquad J_{\mathrm{O}y}=J_{\mathrm{G}y'}+M(a^2+c^2)\tag{9.3.403}$$

with:

$$\overrightarrow{\mathrm{O}G}=a\vec{i}+b\vec{j}+c\vec{k}=x_G\vec{i}+y_G\vec{j}+z_G\vec{k}\tag{9.3.404}$$

We fall back on the classic Huygens theorem since a^2+b^2 is none other than the squared distance between the axis Oz and Gz and same for b^2+c^2 that is the squared distance between Ox and Gx and a^2+c^2 which is the distance between Oy and Gy.

If we now focus on the products of inertia, we get:

$$J_{xy}=-\int xy\mathrm{d}m=-\int(x'+a)(y'+b)\mathrm{d}m=-\int x'y'\mathrm{d}m-a\int y'\mathrm{d}m-b\int x'\mathrm{d}m-ab\int\mathrm{d}m\tag{9.3.405}$$

Therefore, if O' coincide with G:

$$\begin{aligned}J_{xy}&=J_{x'y'}-Mab\\ J_{xz}&=J_{x'z'}-Mac\\ J_{yz}&=J_{y'z'}-Mbc\end{aligned}\tag{9.3.406}$$

In summary, the "Huygens generalized theorem" is written:

$$\boxed{[J_0]_{(\vec{i},\vec{j},\vec{k})}=[J_G]_{(\vec{i},\vec{j},\vec{k})}+\begin{pmatrix}M(y_G^2+z_G^2) & -Mx_Gy_G & -Mx_Gz_G\\ -Mx_Gy_G & M(x_G^2+z_G^2) & -My_Gz_G\\ -Mx_Gz_G & -My_Gz_G & M(x_G^2+y_G^2)\end{pmatrix}}\tag{9.3.407}$$

The inertia tensor being real and symmetric, we have proved in the section of Linear Algebra (spectral theorem at page) that it is always possible to find three perpendicular directions of vectors $\vec{e}_1,\vec{e}_2,\vec{e}_3$ such as the symmetrical tensor (matrix) is diagonalisable:

$$[J_0]_{\vec{e}_1,\vec{e}_2,\vec{e}_3}=\begin{pmatrix}J_1 & 0 & 0\\ 0 & J_2 & 0\\ 0 & 0 & J_3\end{pmatrix}\tag{9.3.408}$$

The trihedron formed by the vector $\vec{e}_1,\vec{e}_2,\vec{e}_3$ is named "main trihedron of inertia" and its axes are named "principal axes of inertia". In this reference frame $[J_0]$ takes the name of "principal inertia tensor". If furthermore O is assimilated to G, we speak of "central tensor of inertia".

In fact, to find the moments of inertia relatively to the principal axes it is almost never necessary to diagonalise the inertia tensor because it is often enough to be guided by the symmetry of the system. We'll see the following theorems that if there are axes or planes of symmetry for the mass distribution, the axes of inertia are easy to find. In addition, the system is generally simple enough (or sufficiently broken down into simple elements ...) for these axes to be obvious.

Theorem 9.5. If the system has a material plane of symmetry (i.e.: $\rho(A)=\rho(A')$ if A is the symmetric of A' relatively to the plane) then any axis perpendicular to this plane is a principal axis of inertia and therefore the inertia matrix reduce to:

$$J_{xy}=\begin{pmatrix} J_{\mathrm{O}x} & J_{xy} & 0 \\ J_{xy} & J_{\mathrm{O}y} & J_{yz} \\ 0 & 0 & J_{\mathrm{O}z} \end{pmatrix} \tag{9.3.409}$$

Proof 9.5.1. Let us choose a reference frame $x\mathrm{O}y$ in the plane relatively to which the system has a mass distribution that is symmetric and $\mathrm{O}z$ an axis perpendicular to this plane. To calculate $\int xz\mathrm{d}m$ or $\int yz\mathrm{d}m$ let us group the points by pairs, symmetrical to $x\mathrm{O}y$. that is to say such that $z_A=-z_{A'}$. We then have:

$$x_Az_A+x_{A'}z_{A'}=0 \tag{9.3.410}$$

and even:

$$y_Az_A+y_{A'}z_{A'}=0 \tag{9.3.411}$$

that is to say, as (material symmetry!):

$$\mathrm{d}m_A=\mathrm{d}m_{A'} \tag{9.3.412}$$

that all contributions of symmetrical pairs of points are zero, which implies:

$$J_{xz}=J_{yz}=0 \tag{9.3.413}$$

that is to say, the z axis is a main direction of inertia.

■ Q.E.D.

Theorem 9.6. Let us Choose $\mathrm{O}z$ as axis of symmetry. As above, we have:

$$\int xz\mathrm{d}m=\int yz\mathrm{d}m=0 \tag{9.3.414}$$

Proof 9.6.1. Indeed, because if we group the points by pairs A and A' symmetrical to $\mathrm{O}z$, we have:

$$x_A=-x_A \qquad y_A=-y_{A'} \tag{9.3.415}$$

but as $z_A=z_{A'}$ we have always:

$$x_Az_A+x_{A'}z_{A'}=0 \tag{9.3.416}$$

and even:

$$y_Az_A+y_{A'}z_{A'}=0 \tag{9.3.417}$$

■ Q.E.D.

Remark

When we have identified two principal axes of inertia through previous symmetries, the third is simply the necessary one to complete an orthogonal (trihedron) axis system.

Theorem 9.7. If a system admits an axis of revolution for its mass distribution, then all orthogonal trihedron including the axis of revolution, is the principal trihedron of inertia. The material system is then said to be a "cylindrical system" and inside the principal inertial trihedron the inertial tensor takes the form (assuming that the axis of rotation is the third axis of the coordinate system):

$$[J_0]_{\vec{e}_1,\vec{e}_2,\vec{e}_3}=\begin{pmatrix} J & 0 & 0 \\ 0 & J & 0 \\ 0 & 0 & J' \end{pmatrix} \tag{9.3.418}$$

Proof 9.7.1. If Oz is an axis of revolution, any plane including Oz is a plane of symmetry and line perpendicular to Oz is principal axis of inertia (first theorem). In addition, all these lines perpendicular to Oz are equivalent.

■ Q.E.D.

Definition (#9.3.442): If the matrix of inertia O of a material system is of the type:

$$[J_0]_{\vec{e}_1,\vec{e}_2,\vec{e}_3}=\begin{pmatrix} J & 0 & 0 \\ 0 & J & 0 \\ 0 & 0 & J \end{pmatrix} \tag{9.3.419}$$

then we say that the system is a "spherical system" (or a "spherically symmetric system").

Remark

The systematic choice of a main trihedron of inertia gives the possibility to reduce the inertia tensor of 6 to 3 components only, calculated once and for all. However, this choice involves the use of a base that will most often be in motion relative to the repository used, which may pose problems derivations with respect to time of the basis vectors. We can then, if it's easier, obtain the components of the tensor of symmetry in any base with a matrix of bases change between the main base and the base used for the calculation of the main trihedron of inertia.

Theorem 9.8. When the moments of inertia of a solid are known in the directions of all principal axes of inertia, we can easily determine the moment of inertia J with respect to any other axis through the center of gravity using what we name an "ellipsoid of inertia" (not to be confused with the moment of inertia of an ellipsoid - proved in the section Geometric Shapes at page 2981).

Proof 9.8.1. Given three axes, centered on G, parallel to the main axes. In their directions, let us choose lengths proportional to:

$$A=\frac{1}{\sqrt{J_x}} \qquad B=\frac{1}{\sqrt{J_y}} \qquad C=\frac{1}{\sqrt{J_z}} \tag{9.3.420}$$

In this phase space of moments of inertia, any point $P=(x,y,z)$ denotes a moment of inertia J such that:

$$||\overrightarrow{GP}||=x^2+y^2+z^2=\frac{1}{J} \tag{9.3.421}$$

To determine J based on the J_x,J_y,J_z, without having to calculate x,y,z, we identify the cosine directions (see section Vector Calculus page 1811) of the axis of rotation to those of the straight line $\overline{GP}$:

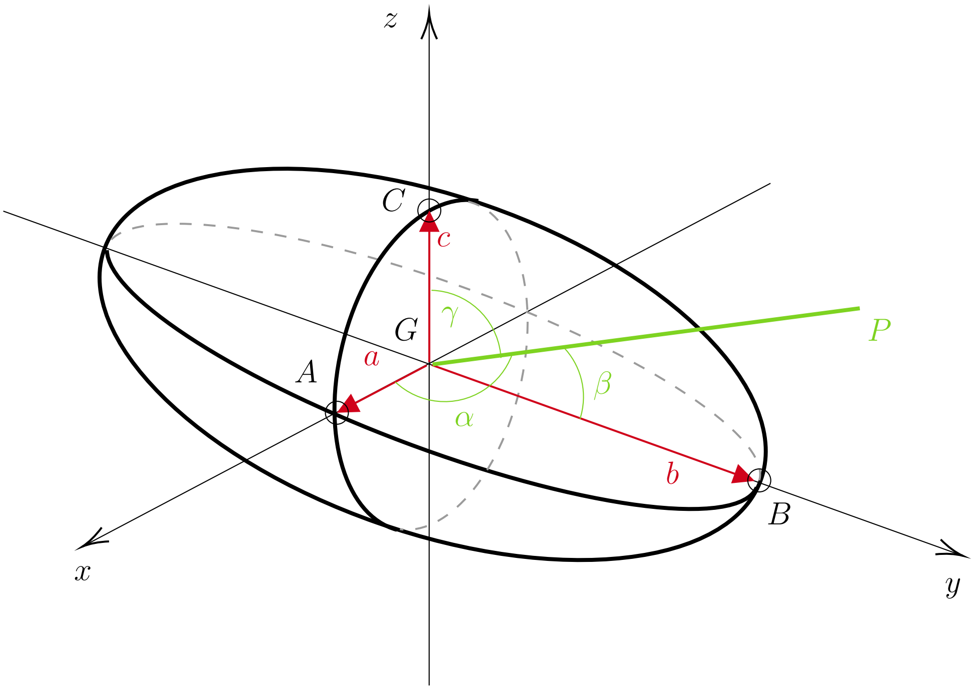


Figure 9.55: **Illustration of the ellipsoid of inertia**

Thus we have:

$$(\cos(\alpha),\cos(\beta),\cos(\gamma))=\left(\frac{x}{||\overrightarrow{GP}||},\frac{y}{||\overrightarrow{GP}||},\frac{z}{||\overrightarrow{GP}||}\right)=\left(\frac{x}{\dfrac{1}{\sqrt{J}}},\frac{y}{\dfrac{1}{\sqrt{J}}},\frac{z}{\dfrac{1}{\sqrt{J}}}\right)=\sqrt{J}(x,y,z) \tag{9.3.422}$$

Therefore:

$$x=\frac{\cos(\alpha)}{\sqrt{J}}\qquad y=\frac{\cos(\beta)}{\sqrt{J}}\qquad z=\frac{\cos(\gamma)}{\sqrt{J}} \tag{9.3.423}$$

Therefore:

$$J||\overrightarrow{GP}||^2=Jx^2+Jy^2+Jz^2=1 \tag{9.3.424}$$

We can now calculate the conditions of normalization of this relation. Thus, if $y=z=0$ and $x=a$, we have:

$$Jx^2+Jy^2+Jz^2=JA^2=1\Rightarrow A^2=\frac{1}{J}=\frac{1}{J_x} \tag{9.3.425}$$

Respectively we will have:

$$B^2=\frac{1}{J}=\frac{1}{J_y} \qquad C^2=\frac{1}{J}=\frac{1}{J_z} \tag{9.3.426}$$

As:

$$A=\frac{1}{\sqrt{J_x}}\Rightarrow A^2=\frac{1}{J_x} \qquad B=\frac{1}{\sqrt{J_y}}\Rightarrow B^2=\frac{1}{J_y} \qquad C=\frac{1}{\sqrt{J_z}}\Rightarrow C^2=\frac{1}{J_z} \tag{9.3.427}$$

■ Q.E.D.

Which brings us to write:

$$J_x x^2+J_y y^2+J_z z^2=\frac{x^2}{A^2}+\frac{y^2}{B^2}+\frac{z^2}{C^2}=1 \tag{9.3.428}$$

By substitution, we get:

$$\frac{x^2}{A^2}+\frac{y^2}{B^2}+\frac{z^2}{C^2}=\frac{1}{J}\left(\frac{\cos^2(\alpha)}{A^2}+\frac{\cos^2(\beta)}{B^2}+\frac{\cos^2(\gamma)}{C^2}\right)=\frac{1}{J}\left(J_x\cos^2(\alpha)+J_y\cos^2(\beta)+J_z\cos^2(\gamma)\right) \tag{9.3.429}$$

So finally:

$$\boxed{J_x\cos^2(\alpha)+J_y\cos^2(\beta)+J_z\cos^2(\gamma)=J} \tag{9.3.430}$$

Thus, knowing the moments of inertia of a body with respect to its principal axis J_x, J_y, J_z, we can know its moment of inertia relatively to any axis having an angle α,β,γ relatively to the main axes.

In other words, the moment of inertia J of a symmetric body like a sphere, ellipsoid, etc. around any general axis (here $\overrightarrow{GP}$) can be expressed as a linear combination of the moments of inertia around the principal axes (i.e. thanks to the squares of the cosines of the angles of the line OP with the x-, y- and z-axis. This is as powerful result used quite a lot in Astronomy and Astrophysics.

9.3.8.2.2 Euler's rotation equation

In what follow we will present a derivation in modern fashion of "Euler rotation equations", or also sometimes named "Euler equations", that is almost a simple copy/paste of Vedat Tanriverdi paper *Euler's derivation of rigid body equations*. This derivation can help understand rigid body rotations and inertia products. We will start by explaining the general structure and continue by giving derivations of Euler equations in the stationary reference frame and in the body reference frame.

Leonhard Euler first derived equations in the stationary reference frame, and then he realized that moments of inertia are time-dependent. Then, he derived equations in the body reference frame. We will also follow the same path!

In the figure below one can see a rigid body, stationary reference frame (x', y', z'), body reference frame (x, y, z), applied force $\vec{F}_a$ and position vector $\vec{l}$ showing acting position of the force. In the figure, the rigid body is represented by a stone to emphasize that it can have any shape, and it should be solid. Euler defines a rigid body with the usage of solid instead of rigid by following statement "*A body is called solid whose interior is not subject to any change, or which is such that all its parts constantly maintain the same relative position, whatever motion the whole body may have.*".

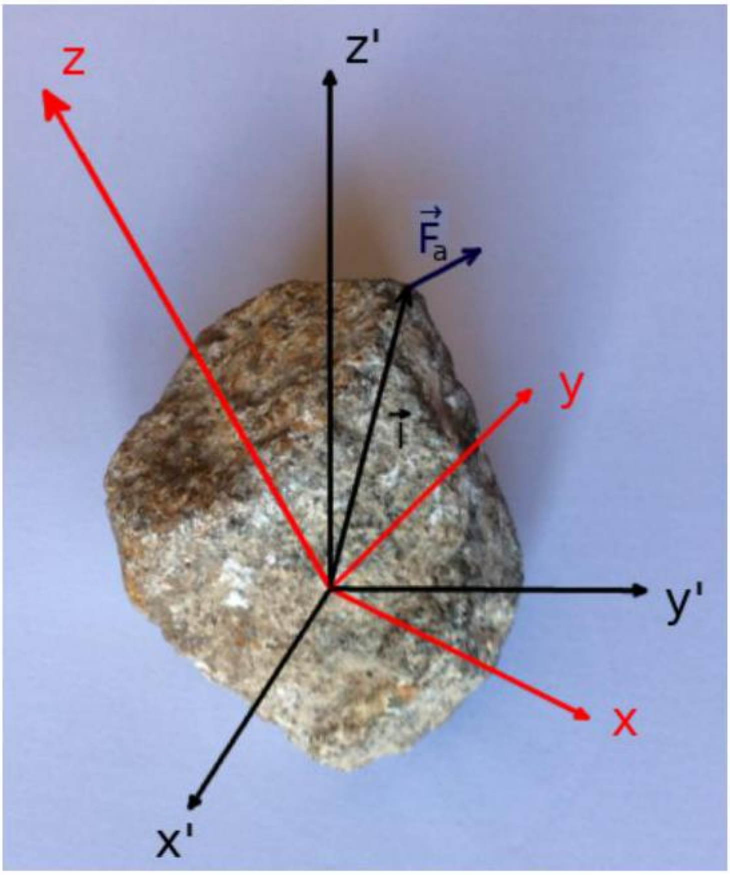

Figure 9.56: A rigid body (stone), stationary reference frame (x', y', z'), body reference frame (x, y, z), applied force $\vec{F}_a$ and position vector $\vec{l}$.

In general, a rigid body can make both translational and rotational motion. In this work, we will follow Euler and will consider only the rotational part of the motion. In the fibure above the origins of reference frames are fixed to the (approximate) center of mass.

We assume that the axes of the body reference frame lie on the principal axes of the rigid body. This assumption will provide simplicities in the calculations in the body reference frame by letting inertia products equal to zero.

An applied force $\vec{F}_a$ acting on the rigid body can cause changes in its angular momentum. We will follow Euler and consider an infinitesimal part of the rigid body to find how applied force changes the rigid body's angular momentum. This infinitesimal part should not lie on the rotation axis for the sake of generality.

9.3.8.2.2.1 Derivation in the stationary reference frame

In this section, we will follow the steps of Euler's derivation for the rotation of a rigid body in a stationary or inertial reference frame.

Like Euler, we will consider an infinitesimal part of the rotating rigid body. We can write its position in a stationary reference frame as:

$$\vec{r}=x'\hat{x}'+y'\hat{y}'+z'\hat{z}' \tag{9.3.431}$$

We can write the angular velocity of this infinitesimal part as:

$$\vec{w}=w_{x'}\hat{x}'+w_{y'}\hat{y}'+w_{z'}\hat{z}' \tag{9.3.432}$$

Then, we can obtain its velocity from the cross product $\vec{v}=\vec{w}\times\vec{r}$ as:

$$\vec{v}=\left(z'w_{y'}-y'w_{z'}\right)\hat{x}'-\left(z'w_{x'}-x'w_{z'}\right)\hat{y}'+\left(y'w_{x'}-x'w_{y'}\right)\hat{z}' \tag{9.3.433}$$

As a result, we can write the components of velocity as:

$$\begin{aligned}\frac{\mathrm{d}x'}{\mathrm{d}t}&=z'w_{y'}-y'w_{z'}\\ \frac{\mathrm{d}y'}{\mathrm{d}t}&=x'w_{z'}-z'w_{x'}\\ \frac{\mathrm{d}z'}{\mathrm{d}t}&=y'w_{x'}-x'w_{y'}\end{aligned} \tag{9.3.434}$$

If we take the derivative of these with respect to time and use them in derivatives, we can get components of acceleration as:

$$\begin{aligned}\frac{\mathrm{d}^2x'}{\mathrm{d}t^2}&=z'\dot{w}_{y'}-y'\dot{w}_{z'}+y'w_{x'}w_{y'}-x'w_{y'}^2-x'w_{z'}^2+z'w_{z'}w_{x'}\\ \frac{\mathrm{d}^2y'}{\mathrm{d}t^2}&=x'\dot{w}_{z'}-z'\dot{w}_{x'}+z'w_{y'}w_{z'}-y'w_{z'}^2-y'w_{x'}^2+x'w_{x'}w_{y'}\\ \frac{\mathrm{d}^2z'}{\mathrm{d}t^2}&=y'\dot{w}_{x'}-x'\dot{w}_{y'}+x'w_{z'}w_{x'}-z'w_{x'}^2-z'w_{y'}^2+y'w_{y'}w_{z'}\end{aligned} \tag{9.3.435}$$

By multiplying components of acceleration with the mass of the infinitesimal part, m, we can get components of force $\vec{F}=F_{x'}\hat{x}'+F_{y'}\hat{y}'+F_{z'}\hat{z}'$ according to Newton's second law $\vec{F}=m\vec{a}$. Then by using the force $\vec{F}$ and the equations above, we can obtain moments of the force (torque) $M_{x'}=y'F_{z'}-z'F_{y'}$, $M_{y'}=z'F_{x'}-x'F_{z'}$ and $M_{z'}=x'F_{y'}-y'F_{x'}$ as:

$$\begin{aligned}\mathrm{d}M_{x'}=&\mathrm{d}m\left[\left(y'^2+z'^2\right)\dot{w}_{x'}-x'y'\dot{w}_{y'}-x'z'\dot{w}_{z'}+x'y'w_{x'}w_{z'}-x'z'w_{x'}w_{y'}\right.\\ &\left.-y'z'\left(w_{y'}^2-w_{z'}^2\right)+w_{y'}w_{z'}\left(y'^2-z'^2\right)\right]\\ \mathrm{d}M_{y'}=&\mathrm{d}m\left[\left(x'^2+z'^2\right)\dot{w}_{y'}-x'y'\dot{w}_{x'}-y'z'\dot{w}_{z'}+y'z'w_{x'}w_{y'}-y'x'w_{y'}w_{z'}\right.\\ &\left.-x'z'\left(w_{z'}^2-w_{x'}^2\right)+w_{x'}w_{z'}\left(z'^2-x'^2\right)\right]\\ \mathrm{d}M_{z'}=&\mathrm{d}m\left[\left(x'^2+y'^2\right)\dot{w}_{z'}-x'z'\dot{w}_{x'}-y'z'\dot{w}_{y'}+x'z'w_{y'}w_{z'}-y'z'w_{x'}w_{z'}\right.\\ &\left.-x'y'\left(w_{x'}^2-w_{y'}^2\right)+w_{x'}w_{y'}\left(x'^2-y'^2\right)\right]\end{aligned} \tag{9.3.436}$$

We will integrate these equations to find the effect of applied force on the totality of the rigid body. Integration of the left-hand side gives the moment of the applied force relevant to that axis, e.g., $M_{x'}=\int \mathrm{d}M'_x$. By using integrals at the right-hand side, we can define components of moments of inertia tensor as:

$$\begin{array}{ll} J_{x'x'}=\int\left(y'^2+z'^2\right)\mathrm{d}m, & J_{x'y'}=J_{y'x'}=-\int \rho x'y'\mathrm{d}m \\ J_{y'y'}=\int\left(x'^2+z'^2\right)\mathrm{d}m, & J_{x'z'}=J_{z'x'}=-\int \rho x'z'\mathrm{d}m \\ J_{z'z'}=\int\left(x'^2+y'^2\right)\mathrm{d}m, & J_{y'z'}=J_{z'y'}=-\int y'z'\mathrm{d}m \end{array} \quad (9.3.437)$$

Therefore:

$$\boxed{\begin{aligned} M_{x'}=&J_{x'x'}\dot{w}_{x'}+J_{x'y'}\dot{w}_{y'}+J_{x'z'}\dot{w}_{z'}-J_{x'y'}w_{x'}w_{z'}+J_{x'z'}w_{x'}w_{y'}\\ &+J_{y'z'}\left(w_{y'}^2-w_{z'}^2\right)+w_{y'}w_{z'}\left(J_{z'z'}-J_{y'y'}\right)\\ M_{y'}=&J_{y'y'}\dot{w}_{y'}+J_{x'y'}\dot{w}_{x'}+J_{y'z'}\dot{w}_{z'}-J_{y'z'}w_{x'}w_{y'}+J_{x'y'}w_{y'}w_{z'}\\ &+J_{x'z'}\left(w_{z'}^2-w_{x'}^2\right)+w_{x'}w_{z'}\left(J_{x'x'}-J_{z'z'}\right)\\ M_{z'}=&J_{z'z'}\dot{w}_{z'}+J_{x'z'}\dot{w}_{x'}+J_{y'z'}\dot{w}_{y'}-J_{x'z'}w_{y'}w_{z'}+J_{y'z'}w_{x'}w_{z'}\\ &+J_{x'y'}\left(w_{x'}^2-w_{y'}^2\right)+w_{x'}w_{y'}\left(J_{y'y'}-J_{x'x'}\right) \end{aligned}} \quad (9.3.438)$$

These equations describe the rotation of a rigid body in the stationary reference frame by the effect of the moment of force, $\vec{M}=\vec{F}_a\times\vec{l}$.

In Classical Mechanics, Euler's rotation equations are a vectorial quasilinear first-order ordinary differential equation describing the rotation of a rigid body, using a rotating reference frame with angular velocity ω whose axes are fixed to the body.

One should be careful while using these equations since moments of inertia are (may be) time dependent in the stationary reference frame!

9.3.8.2.2.2 Derivation in the body reference frame

Now we will follow Euler's method in the stationary reference frame to get equations of rigid body rotations in the body reference frame under the influence of torque. We will consider an infinitesimal part of the rigid body again to see the effect of torque on the rotation of that infinitesimal part. The axes of the body reference frame are chosen as the principal axes of the body.

In the body reference frame, we can show the position of an infinitesimal part of the rigid body by:

$$\vec{r}=x\hat{x}+y\hat{y}+z\hat{z} \quad (9.3.439)$$

We can write the components of angular velocity as:

$$\vec{w}=w_x\hat{x}+w_y\hat{y}+w_z\hat{z} \quad (9.3.440)$$

Then, we can get the velocity of the infinitesimal part from cross-product $\vec{v}=\vec{w}\times\vec{r}$ as:

$$\vec{v}=\left(zw_y-yw_z\right)\hat{x}-\left(zw_x-xw_z\right)\hat{y}+\left(yw_x-xw_y\right)\hat{z} \quad (9.3.441)$$

As a result, we can write the components of the velocity as:

$$\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}t}&=zw_y-yw_z\\ \frac{\mathrm{d}y}{\mathrm{d}t}&=xw_z-zw_x\\ \frac{\mathrm{d}z}{\mathrm{d}t}&=yw_x-xw_y\end{aligned} \tag{9.3.442}$$

By taking the time derivative of the equations above and using them, we can find the components of acceleration as:

$$\begin{aligned}\frac{\mathrm{d}^2x}{\mathrm{d}t^2}&=z\dot{w}_y-y\dot{w}_z+yw_xw_y-xw_y^2-xw_z^2+zw_zw_x\\ \frac{\mathrm{d}^2y}{\mathrm{d}t^2}&=x\dot{w}_z-z\dot{w}_x+zw_yw_z-yw_z^2-yw_x^2+xw_xw_y\\ \frac{\mathrm{d}^2z}{\mathrm{d}t^2}&=y\dot{w}_x-x\dot{w}_y+xw_zw_x-zw_x^2-zw_y^2+yw_yw_z\end{aligned} \tag{9.3.443}$$

where dots over w_i's represent again time derivatives. According to Newton's second law, $\vec{F}=m\vec{a}$, by multiplying the equations above with mass of the infinitesimal part, m, we can get components of the force $\vec{F}=m\mathrm{d}^2x/\mathrm{d}t^2\hat{x}+m\mathrm{d}^2y/\mathrm{d}t^2\hat{y}+m\mathrm{d}^2z/\mathrm{d}t^2\hat{z}$. This force is responsible for the acceleration of the rigid body's infinitesimal part and different than the applied force. It results from the combination of applied force and rigidity of the object.

Then by using the force $\vec{F}$ as we did before we can obtain the effects of moments of the force on angular accelerations and angular velocities as:

$$\begin{aligned}\mathrm{d}M_x=&\mathrm{d}m\left[\left(y^2+z^2\right)\dot{w}_x-xy\dot{w}_y-xz\dot{w}_z+xyw_xw_z-xzw_xw_y\right.\\ &\left.-yz\left(w_y^2-w_z^2\right)+w_yw_z\left(y^2-z^2\right)\right]\\ \mathrm{d}M_y=&\mathrm{d}m\left[\left(x^2+z^2\right)\dot{w}_y-xy\dot{w}_x-yz\dot{w}_z+yzw_xw_y-yxw_yw_z\right.\\ &\left.-xz\left(w_z^2-w_x^2\right)+w_xw_z\left(z^2-x^2\right)\right]\\ \mathrm{d}M_z=&\mathrm{d}m\left[\left(x^2+y^2\right)\dot{w}_z-xz\dot{w}_x-yz\dot{w}_y+xzw_yw_z-yzw_xw_z\right.\\ &\left.-xy\left(w_x^2-w_y^2\right)+w_xw_y\left(x^2-y^2\right)\right]\end{aligned} \tag{9.3.444}$$

We can integrate these equations over the volume of the rigid body. If we consider the torque on different infinitesimal parts, it changes as the distance from the rotation axis changes, and the moments of force are distributed over the rigid body to satisfy the rotation of the rigid body as a whole with the help of atomic interactions. This is the result of the object's rigidity. Then, the integration of the left-hand side gives torque relevant to that axis, e.g., $M_x=\int \mathrm{d}M_x$. Integrals at the right-hand side are related to moments of inertia and inertia products, and they are defined as:

$$\begin{aligned}J_{xx}&=\int\left(y^2+z^2\right)\mathrm{d}m, & J_{xy}&=J_{yx}=-\int xy\mathrm{d}m=0\\ J_{yy}&=\int\left(x^2+z^2\right)\mathrm{d}m, & J_{xz}&=J_{zx}=-\int xz\mathrm{d}m=0\\ J_{zz}&=\int\left(x^2+y^2\right)\mathrm{d}m, & J_{yz}&=J_{zy}=-\int yz\mathrm{d}m=0\end{aligned} \tag{9.3.445}$$

We choose the body axes as principal axes, then terms in the second column, inertia products, are equal to zero since the definition of principal axes is based on this.

Then the integration of these equations over the volume of the rigid body gives:

$$\boxed{\begin{aligned} M_x &= J_{xx}\dot{w}_x - w_y w_z \left(J_{yy} - J_{zz}\right) \\ M_y &= J_{yy}\dot{w}_y - w_z w_x \left(J_{zz} - J_{xx}\right) \\ M_z &= J_{zz}\dot{w}_z - w_x w_y \left(J_{xx} - J_{yy}\right) \end{aligned}} \qquad (9.3.446)$$

The above relation is most famously know under the following shape:

$$\boxed{\vec{M} = \vec{J}\dot{\vec{\omega}} + \vec{\omega} \times (\vec{J}\vec{\omega})} \qquad (9.3.447)$$

or sometimes:

$$\vec{M} = \vec{L} + \vec{\omega} \times \vec{L} \qquad (9.3.448)$$

or sometimes:

$$\tau_\alpha = J_\alpha \dot{\omega}_\alpha + \varepsilon_{\alpha l k}\omega_l \omega_k J_k \qquad (9.3.449)$$

with α fixed but a sum implied over the repeated l and k indices. Here ε_{abc} is the fully antisymmetric Levi-Civita symbol.

These are Euler equations for rigid bodies describing the change of the angular momentum under the influence of torque, $\vec{M} = \vec{F}_a \times \vec{l}$, in the body reference frame. In these equations, moments of inertia and inertia products are independent of time.

In Classical Mechanics, Euler's rotation equations are a vectorial quasilinear first-order ordinary differential equation describing the rotation of a rigid body, using a rotating reference frame with angular velocity ω whose axes are fixed to the body.

By following Euler's ideas, we have obtained equations describing the rotation of a rigid body. We have used Euler's method to obtain equations in the stationary reference frame. While obtaining equations in the body reference frame, we have followed Euler's method in the stationary reference frame and have not use direction cosines though Euler used them. Our derivation gives the same equations as equations in the body reference frame, known as "Euler equations". The equations in the stationary reference frame are more complicated than the ones in the body reference frame due to non-zero inertia products. In addition to this, it should be remembered that the moments of inertia change in the stationary reference frame during the rotation.

If we rotate a rigid body with an initial effect, it will rotate around one of its principal axes provided that there is not any disturbing effect. We have seen during the derivation that studying rotation of a rigid body by using principal axes provides simplifications since inertia products become zero. In formal definition, principal axes are defined by using inertia products: if we choose an axis passing through the center of mass and if inertia products related to that axis are zero then that axis is principal axes. As we mentioned this axis is physically exist and the rigid body naturally rotates around it, if an initial rotation is given. If we try to define the rotation of a rigid body by using axes other than principal axes, we need to consider inertia products. Moments of inertia and inertia products play a similar role to mass in translational motion, in which mass is related to inertia against the change in linear momentum. Moment of inertia corresponds to the inertia of the rigid body against the change in angular momentum around rotation axis, and inertia product is the inertia of the rigid body against the change in angular momentum around rotation axis due to effects of other rotations and asymmetries in mass distribution.

During the derivation, we considered that the fixed point is the center of mass of the rigid body. However, this derivation is also valid if the fixed point of the rigid body is different than the center of mass. In such cases, the origins should be set to that fixed point, and moments of inertia in the body reference frame should be calculated by considering rotations around the fixed point. This calculation can be done with the help of Steiner's parallel-axis theorem.

During the derivation, we considered an applied force. Any force that can change atomic interactions will deform the object, and it can not be considered as a rigid body anymore. Hence, the force that will be considered in Euler equations should not change the atomic structure. If it changes, other physical interactions should be considered, and such cases are not subject to rigid body rotations.

✍**Example:**

The Earth as an oblate ellipsoid is an object with $J_x = J_y \neq J_z$. Therefore, Euler's rotation equation reduces to (as their at no externe torque on the Earth in first approximation) after rearranging:

$$\begin{aligned}
J_x\dot{\omega}_x &= \omega_y\omega_z\left(J_x - J_z\right)\\
J_y\dot{\omega}_y &= -\omega_x\omega_z\left(J_x - J_z\right)\\
J_z\dot{\omega}_z &= 0
\end{aligned}\tag{9.3.450}$$

So, in this case, we see that ω_z, which is the spin about the symmetric axis, is a constant of motion. And we have using the first two relations by rearranging:

$$\dot{\omega}_1 = \Omega\omega_2 \quad \text{and} \quad \dot{\omega}_2 = -\Omega\omega_1 \tag{9.3.451}$$

where:

$$\Omega = \frac{\omega_z\left(J_x - J_z\right)}{J_x} \tag{9.3.452}$$

These equations are solved by:

$$(\omega_1, \omega_2) = \omega_0(\sin(\Omega t), \cos(\Omega t)) \tag{9.3.453}$$

for any constant ω_0. This means that, in the body frame, the direction of the spin is not constant: it precesses about the $\vec{e}_z$ axis with frequency Ω. The direction of the spin depends on the sign on Ω or, in other words, whether $J_x > J_z$ or $J_x < J_z$.

In an inertial frame, this precession of the spin looks like a wobble. For the Earth we have:

$$\frac{J_x - J_z}{J_x} \cong -\frac{1}{300} \tag{9.3.454}$$

Of course, we know the magnitude of the spin ω_z for the Earth: it is $\omega_3=(1\text{ day })^{-1}$. This information is enough to callculate the frequency of the Earth's wobble in absolute value:

$$\Omega_{\text{Earth}}=\frac{\omega_z\left(J_x-J_z\right)}{J_x}\cong\frac{1}{300} \tag{9.3.455}$$

This calculation was first performed by Euler in 11749 (holocene calendar) who predicted that the Earth completes a wobble every 300 days. Despite many searches, this effect wasn't detected until 11891 (holocene calendar) when Seth Carlo Chandler reanalysed the data and saw a wobble with a period of 427 days. It is now known as the "Chandler wobble". It is very small! The angular velocity ω intercepts the surface of the Earth approximately 10 metres from the North pole and precesses around it. More recent measurements place the frequency at 435 days, with the discrepancy between the predicted 300 days and observed 435 days due to the fact that the Earth is not a rigid body, but is flexible because of tidal effects. Less well understood is why these same tidal effects haven't caused the wobble to dampen and disappear completely. There are various hypothesis about what keeps the wobble alive, from earthquakes to fluctuating pressure at the bottom of the ocean.

9.3.8.2.3 Gyroscope

Ok now that we know quite well what is the angular momentum, the moment of inertia and the Lagrangian (see section Analytical Mechanics page 3155) we can now study one of the most fascinating object of macroscopic physics that combines all these concepts!!!

Definition (#9.3.443): A solid (solid of revolution for simplicity...) which can move freely around a fixed point and quickly turning on itself by definition is a "gyroscope".

Out of their recreational use... because they allow configurations considered as pedagogically exceptional... gyroscopes are an important part of inertial navigation systems (before the advent of GPS...) in aviation, aerospace, marine (boat stabilization), movie/television (stabilization of cameras), weapons (ballistic missiles), tunnel mining and many more. The guide instruments through inertia of these systems consist of gyroscopes and accelerometers, which calculate at any time the exact speed and direction of the system in motion (depending on the movement of the gyroscope a voltage variation is caused). The collected signals are transmitted to a computer that records and then corrects any aberrations of the path.

Remark

Gyroscopes based on other operating principles also exist, such as the electronic, microchip-packaged MEMS gyroscopes found in consumer electronics devices, solid-state ring LASERs, fibre optic gyroscopes, and the extremely sensitive quantum gyroscope.

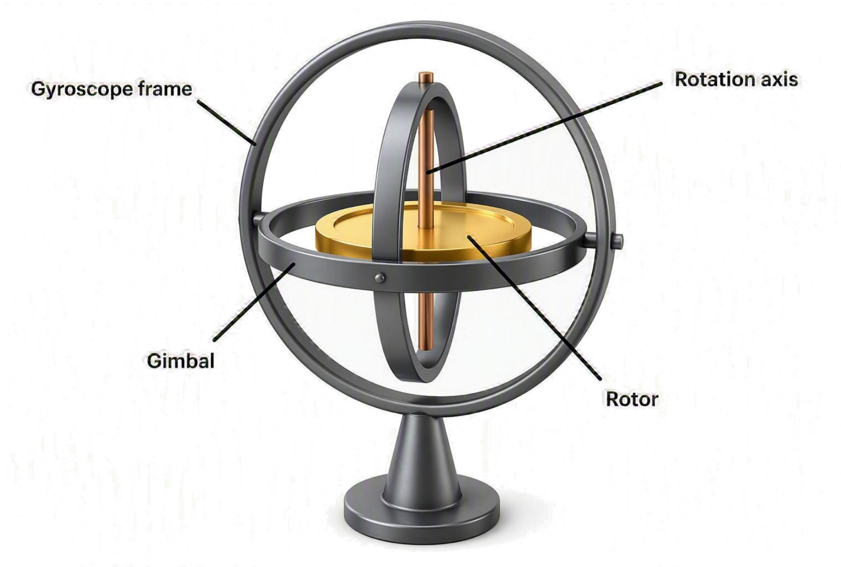

Figure 9.57: **3D Gyroscope**

The planets are another example of famous gyroscopes. The best known example being our Earth rotating around itself and being very massive it's angular momentum makes that its north pole is always (at least in the time scale of a human being...) facing the North star (actually approximately oriented to Polaris) regardless of its position in its orbit (this property of some gyroscopes is named "gyroscopic rigidity").

We will study the gyroscope in two steps:

1. The classical approach (without using Lagrangian mechanics) that is easy to understand but that gives only the possibility to explain the precession angular velocity Ω of the gyroscope.
2. The Lagrangian approach that is more abstract but that opens the door to the understanding of the precession AND the nutation rotation of the gyroscope.

9.3.8.2.3.1 Classical Approach with precession only

The following figure is an example of gyroscope known in laboratories schools named "symmetric weighing gyroscope". This is obviously a special and simplified case but for understanding the basic principle of the gyroscope:

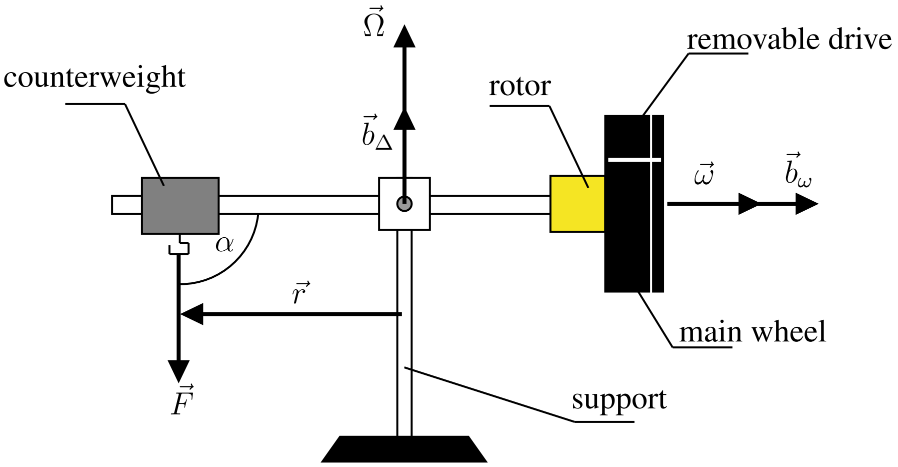

Figure 9.58: Symmetric weighing gyroscope

Consisting of an electric motor whose rotor, the main wheel, form the main mass in rapid angular rotation (a gyroscope of a V2 rocket turn at over $10,000$ rpm). The motor stator is fixed to a rod on which is positioned a counterweight on the opposite side. The assembly is placed on a support on the end of which is a gimbal mounted on a horizontal bearing which allows the gyroscope orientation almost without limitations in all directions.

In this figure we have ω which is the instantaneous angular velocity of the removable disk of radius R, Ω is the rate of precession of the gyroscope (rotation around the support), F is the force of the additional mass m attached to the counterweight and that imbalance the gyroscope, r is the distance of the gyroscope to the counterweight and finally α is the tilt angle that takes the axis of the gyroscope when we do an imbalance by attaching an additional weight to the counterweight.

To begin the theoretical study of this system, remember that have proved above that the angular momentum for a solid having a moment of inertia J is expressed by the following relation:

$$\vec{b}_\omega = J\vec{\omega} \tag{9.3.456}$$

and we saw that all solid in rotation around any axis also has also a momentum that is then customary to write according to what we have seen above:

$$\vec{b}_\Delta = J_\Delta\vec{\Omega} \tag{9.3.457}$$

We also proved above that the rotor, like any rapid mass in rotation, when started or regulated then produced a moment of force given by:

$$\vec{M} = \frac{\mathrm{d}\vec{b}_\omega}{\mathrm{d}t} = J\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t} \tag{9.3.458}$$

which is vectorially collinear to $\vec{\omega}$ and therefore passes through the axis of symmetry of the gyroscope. As we already know, it is this latter relation that puts the best evidence that the gyroscope always keeps the same direction in space even when we move its support.

In other words a free gyroscope driven at a high speed of rotation has for fundamental property to maintain its axis of rotation in a fixed orientation with respect to absolute space. This is what we named the "first gyroscopic law" or "law of fixity".

Typically the "Foucault gyroscope" shown below, is an excellent practical example of the fixity law, it maintains its orientation regardless of how we handle the support on which it is build:

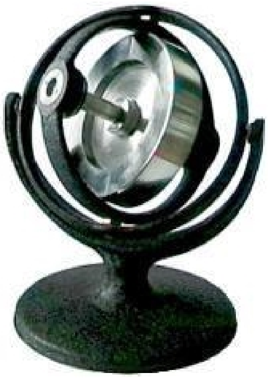

Figure 9.59: **Foucault gyroscope**

If we put the gyroscope a whole day on a table with an engine that maintains the rotation of the central massive disk constant , then we observe the rotation of the Earth because the gyroscope then rotates very slowly on itself in 24 hours!

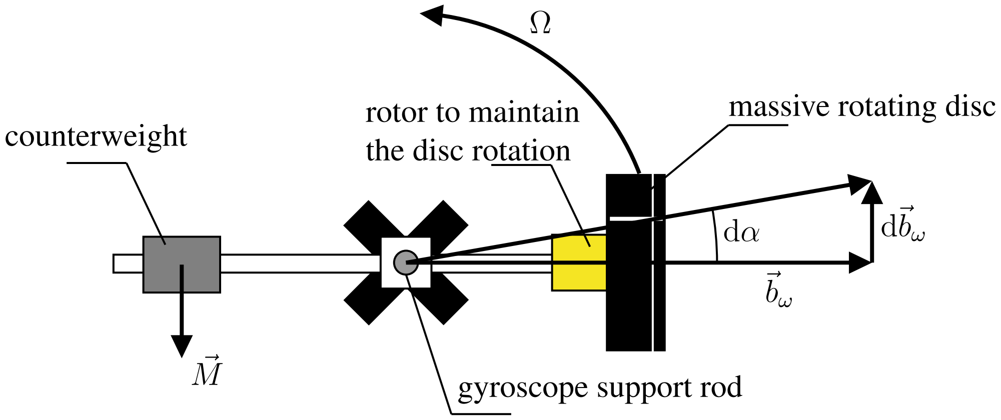
To return to our mathematical considerations ... now let's look at the force momentum of the counterweight that imbalance our symmetrical gyroscope while the disc is rotating, and generates a general rotation of the gyroscope as experience reveals. We then have for the force momentum making rotating the gyroscope about its axis (support rod):

$$M=\|\vec{M}\|=\|\vec{r}\times\vec{F}\|=\|\vec{r}\|\cdot\|\vec{F}\|\sin(\alpha)=rma\sin(\alpha) \qquad (9.3.459)$$

Since the gyroscope does not precess when the system is balanced this mean that the moment of force of the extra weight that imbalance the gyroscope generates an angular momentum according to the relation proved earlier above such that:

$$\frac{\mathrm{d}b_{\omega}}{\mathrm{d}t}=M=rma\sin(\alpha) \qquad (9.3.460)$$

What schematically can be represented as follows (this is our gyroscope seen from above):



Ω
rotor to maintain
the disc rotation
massive rotating disc
counterweight
$\mathrm{d}\alpha$
$\mathrm{d}\vec{b}_\omega$
$\vec{b}_\omega$
$\vec{M}$
gyroscope support rod

Or the real life equivalent (that should help to reader to better imagine what represents the above figure...):

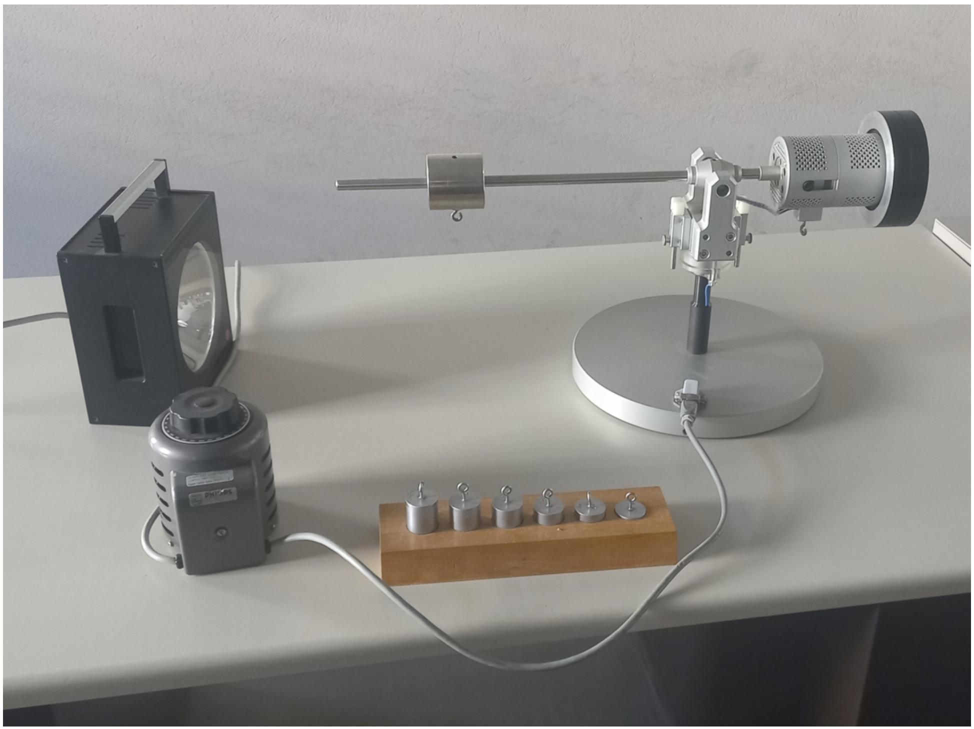


Figure 9.60: Weighted gyroscope with rotor from the physics laboratory of the HES Geneva

We then have, as soon as the gyroscope starts to rotate (in a circular motion):

$$\tan(\mathrm{d}\alpha)=\frac{||\mathrm{d}\vec{b}_\omega||}{\vec{b}_\omega}\cong\frac{\mathrm{d}b_\omega}{b_\omega} \qquad (9.3.461)$$

Taking the Taylor approximation (see section Sequences and Series page 1696) to the first order of the tangent for small angles we get:

$$\mathrm{d}\alpha\cong\frac{\mathrm{d}b_\omega}{b_\omega} \qquad (9.3.462)$$

Let us assume, to simplify the study of the problem, that the variation of total angular momentum with respect to the rotation axis of the gyroscope (that is to say the support rod!) can be assimilated to the angular momentum of the rotor only if that latter is turning fast enough and that its mass is large enough. Which means:

$$\frac{\mathrm{d}\vec{b}_\omega}{\mathrm{d}t} \gg \frac{\mathrm{d}\vec{b}_\Delta}{\mathrm{d}t} \tag{9.3.463}$$

Then we have:

$$\frac{\mathrm{d}\vec{b}}{\mathrm{d}t} = \frac{\mathrm{d}(\vec{b}_\Delta + \vec{b}_\omega)}{\mathrm{d}t} \cong \frac{\mathrm{d}\vec{b}_\omega}{\mathrm{d}t} \tag{9.3.464}$$

and therefore because of this approximation by entire force momentum is assigned to the change in angular momentum of the rotor itself:

$$\mathrm{d}\alpha \cong \frac{M\mathrm{d}t}{b_\omega} \tag{9.3.465}$$

It finally comes for the precession angular velocity:

$$\boxed{\Omega \cong \frac{\mathrm{d}\alpha}{\mathrm{d}t} = \frac{M}{b_\omega} = \frac{rF\sin(\alpha)}{J\omega}} \tag{9.3.466}$$

Therefore when the symmetric weighted gyroscope is balanced (when M is zero in the numerator of the fraction or if you prefer: $\sin(\alpha) = 0$), its angular momentum therefore maintains a fixed orientation regardless of the value of the denominator since its precession Ω will be always equal to zero.

Definition (#9.3.444): The rotational movement resulting from a non-equilibrated gyroscope is named "precession movement" when it is caused intentionally, and "drift" when it is due to a disruptive element.

Let us finally indicate the playful gyroscopes for small children as the spinner below:

that we can roughly represent as following (side view and respectively top view) to make still some classical mathematical analysis (do the test with your children to see if it interests them as much as the toy...):

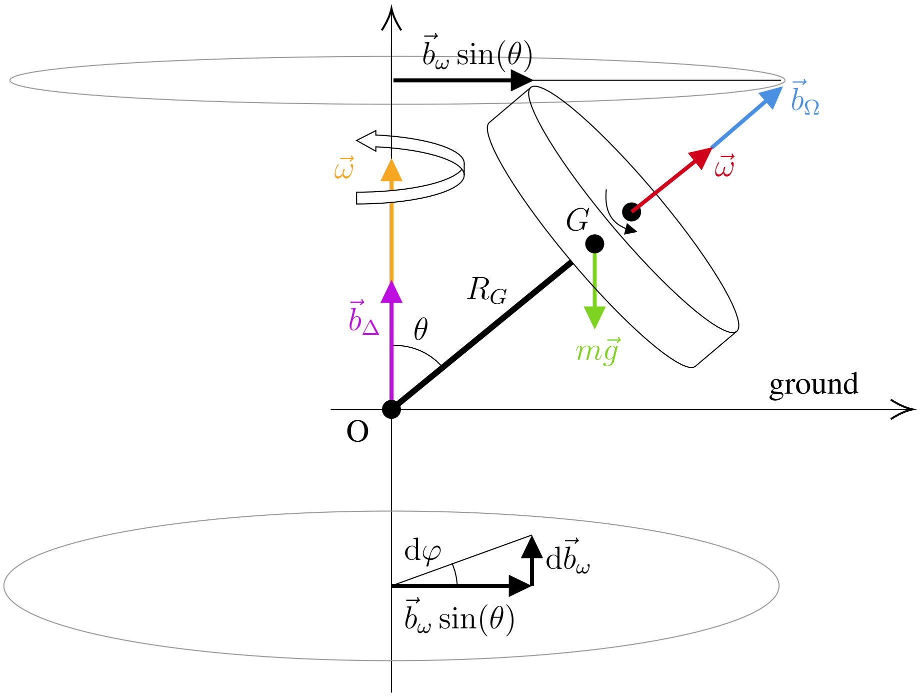

Figure 9.61: **Gyroscope spinner**

where we make the hypothesis that the end of the axis of the spinning top (other name for "gyroscope spinner") is placed on the ground without possibility of slippage and that it has a constant angular velocity ω and that the latter is big enough to not have its angle θ which varies in time (otherwise another effect appear named "nutation" that we can only introduce robustly using Lagrangian Mechanics).

Using the same technique as for the symmetric weighted gyroscope we have (well... we could have also used simply the relation $L=\alpha R$ proved in the section Trigonometry...):

$$\mathrm{d}b_\omega = b_\omega \sin(\theta)\mathrm{d}\varphi \tag{9.3.467}$$

We also have for the moment of force (torque):

$$M = R_G mg \sin(\theta) \tag{9.3.468}$$

But again, the angular momentum changes! Indeed, so we have in this particular case:

$$\mathrm{d}b_\omega = b_\omega \sin(\theta)\mathrm{d}\varphi \tag{9.3.469}$$

it follows that under the same assumptions as the symmetric weighted gyroscope that:

$$\frac{\mathrm{d}b}{\mathrm{d}t} \cong \frac{\mathrm{d}b_\omega}{\mathrm{d}t} = b_\omega \sin(\theta)\frac{\mathrm{d}\varphi}{\mathrm{d}t} = b_\omega \sin(\theta)\Omega \tag{9.3.470}$$

hence in vector form:

$$\frac{\mathrm{d}\vec{b}_\omega}{\mathrm{d}t} = \vec{\Omega} \times \vec{b}_\omega \tag{9.3.471}$$

and we know that this last relation (proved made earlier above) can be completed by writing:

$$\frac{\mathrm{d}\vec{b}_\omega}{\mathrm{d}t} = \vec{\Omega} \times \vec{b}_\omega = \vec{M} \tag{9.3.472}$$

It comes then:

$$\Omega b_\omega \sin(\theta) = R_G mg \sin(\theta) \tag{9.3.473}$$

Hence:

$$\boxed{\Omega = \frac{R_G mg}{b_\omega} = \frac{R_G mg}{J\omega}} \tag{9.3.474}$$

We see that the difference with the symmetric weighted gyroscope is that the speed of precession is then independent of the angle!

Remarks

R1. A cyclist travelling in a straight line is stabilized (fixity law requirement!) by the angular momentum of its wheels perpendicular to the rolling direction (the wheels behaves as a gyroscope).

R2. Probably without realizing it, we tip up while biking in a curve to produce a precession in the wheels and turn more easily. Indeed the precession movement rotates the bicycle wheel in the direction you look without the need to turn the handlebars... !

9.3.8.2.3.2 Lagrangian Approach with precession and nutation

Symmetric spinning top is a case studied by Lagrange in 11788 (holocene calendar). After 110 years, in 11897-11898 (holocene calendar) Felix Klein and Arnold Sommerfeld published two volumes on the topic, whereas in 11897 (holocene calendar) Klein separately published a shorter monograph on the mathematical theory of the top. In the eastern world literature, one of the oldest papers is probably due to Germanovich Appel'rot (11894 according to holocene calendar). Explicit integration of motion equations, to give the nutation in terms of elliptic integrals was given at the end of 119th century (holocene calendar).

The analysis of the symmetrical top (spinning top) is a fascinating topic in Classical Mechanics. It is a simple system that exhibits counter-intuitive balancing behaviour. It's famous "gravity-defying" behaviour to remain perched on its pointed is well known (a simple internet search reveals many references concerning the spinning tops and gyroscopes as if they were "magical" instruments that defy gravity). The following developments first explores the Lagrangian formulation of the symmetrical top in a uniform force-field (e.g. gravity). After establishing a few constraints, a dynamic model is presented. From this model, precession rates and nutation behaviour are deduced!

Figure 9.62: **Symmetrical top gyroscope in equilibrium**

The geometry of the symmetric gyroscopic top in a gravitational field consists of a "heavy" wheel on a narrow stem whose bottom point is fixed to the origin, but is free to rotate (as show in the figure below):

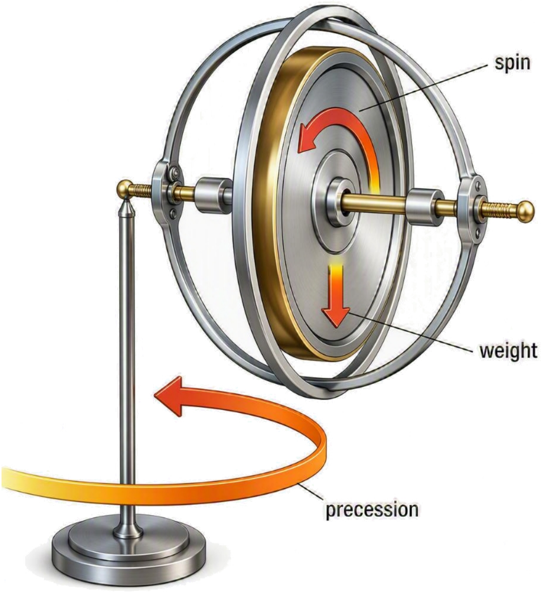

Figure 9.63: **Spinning top in precession only**

The z' axis passes through the center of rotation of the top. The motion of the top can be expressed in terms of the so-named Eulerian angles (ϕ,θ,ψ). The variable θ is the angle that the z' axis makes with the stationary z axis. The variable ϕ is the angle that is formed by the projection of the z' axis in the $x-y$ plane and the x axis. Counter-clockwise rotation yields positive angles. The variable ψ is the angular position around the z' axis. Since our top is circularly symmetric, the choice of origin for is arbitrary. We will only be concerned with the rate of angular rotation of the wheel about z', given by $\dot{\psi}$ ($\omega=\dot{\psi}$ on the above figure). Other dynamical variables of interest are the time derivatives of ϕ and θ. These variables $\dot{\phi}$ and $\dot{\theta}$ describe the precession and nutation of the top. The length of the stem is R_G. We assume the mass of the stem is negligible with respect to that of the wheel m. The acceleration due to uniform gravity is g and is assumed to point downwards along the z axis:

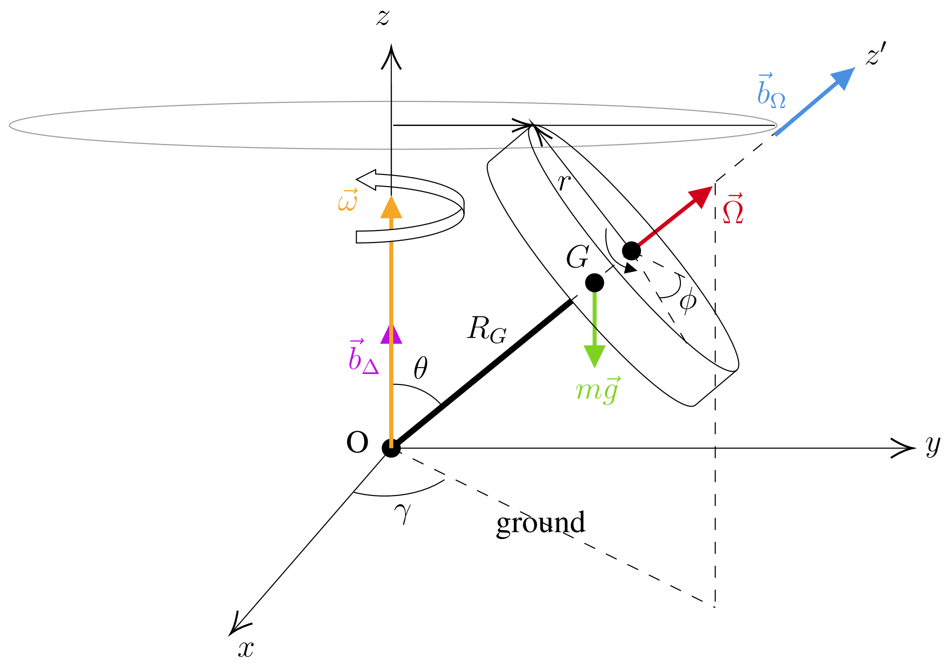

Figure 9.64: **Schematic view of spinning top**

The most convenient way to derive the equations of motion for this system is to use the Lagrangian of Hamiltonian formalism as we have already mentioned it (see section Analytical Mechanics page 3155).

First let us recall that in the section of Euclidean Geometry we have proved the following group of relations:

$$\begin{aligned}\Omega_1&=\sin(\theta)\sin(\gamma)\dot{\phi}+\cos(\gamma)\dot{\theta}\\ \Omega_2&=\sin(\theta)\cos(\gamma)\dot{\phi}-\sin(\gamma)\dot{\theta}\\ \Omega_3&=\cos(\theta)\dot{\phi}+\dot{\gamma}\end{aligned} \tag{9.3.475}$$

named "kinematic Euler equations" and is useful to express the rotation speed (around any axis of rotation) of a body in its own reference frame (most of time its center of mass).

Let us choose O as origin for our reference frame and we will choose the principal axes of inertia as the body reference frame. The total kinetic energy of the object will then be:

$$E_{\text{tot}}=E_c+E_{\text{rot.}}+E_p=\frac{1}{2}m\vec{v}_G^2+\sum_{i=1}^{n}\frac{1}{2}J_i\Omega_i^2+mgR_G\cos(\theta) \tag{9.3.476}$$

As we take $\overrightarrow{\text{O}\Omega}$ as instantaneous axis of rotation relatively to an observer in O we have $v_G=0$.

If for some readers it is not obvious that:

$$E_p=mgR_G\cos(\theta) \tag{9.3.477}$$

just remember first that $E_p=mgh$ but as our comoving reference frame is oriented along $\overrightarrow{\text{O}\Omega}$ we must project the gravitational force on this axis. As you can see with the extreme trivial situations where $\theta=0$ (vertical spinning top) we have as expected:

$$E_p=mgR_G\cos(0)=mgR_G \tag{9.3.478}$$

and for $\theta = \pi/2$ (spinning top rotation axis in the plane of the ground!) then:

$$E_p = mgR_G \cos\left(\frac{\pi}{2}\right) = 0 \tag{9.3.479}$$

Then it remains:

$$E_{\text{tot}} = \sum_{i=1}^{n} \frac{1}{2} J_i \Omega_i^2 + mgR_G \cos(\theta) = \frac{1}{2} J_1 \Omega_1^2 + \frac{1}{2} J_2 \Omega_2^2 + \frac{1}{2} J_3 \Omega_3^2 + mgR_G \cos(\theta) \tag{9.3.480}$$

where the index 123 corresponds to the notation of the comoving reference frame as seen in the section of Euclidean Geometry during our study of the Euler angles.

For J_1, J_2, J_3 following the proof we made for the inertial moment of a rotating cylinder around its main symmetric axis in the section Geometric Shapes (see page 2959) and using also the parallel axis theorem we have by symmetry of our problem:

$$\begin{aligned} J_1 &= J_\theta = \frac{1}{2} mr^2 + mR_G^2 \\ J_2 &= J_\gamma = \frac{1}{2} mr^2 + mR_G^2 \\ J_3 &= J_\phi = \frac{1}{2} mr^2 \end{aligned} \tag{9.3.481}$$

But for the following developments we will not use the explicit relations above. In this way the reader can choose the spinning top geometry he wants and after just put the $J_1 = J_2$, J_3 (so we not consider an asymmetric spinning top otherwise the general formula is rather complicated) corresponding values in the final formula!

For what will follow we will put $I_\phi := J_3$ and $I_0 := J_1 = J_2$. Therefore:

$$\begin{aligned} E_{\text{tot}} &= \frac{1}{2} I_0 \left(\Omega_2^2 + \Omega_3^2\right) + \frac{1}{2} I_\phi \Omega_1^2 + mgR_G \cos(\theta) \\ &= \frac{1}{2} I_0 \left((\sin(\theta)\sin(\gamma)\dot{\phi} + \cos(\gamma)\dot{\theta})^2 + (\sin(\theta)\cos(\gamma)\dot{\phi} - \sin(\gamma)\dot{\theta})^2 \right) + \frac{1}{2} I_\phi (\cos(\theta)\dot{\phi} + \dot{\gamma})^2 \\ &\quad + mgR_G \cos(\theta) \\ &= \frac{1}{2} I_0 \left(\sin^2(\theta)\dot{\phi}^2 + \dot{\theta}^2 \right) + \frac{1}{2} I_\phi (\cos(\theta)\dot{\phi} + \dot{\gamma})^2 + mgR_G \cos(\theta) \end{aligned} \tag{9.3.482}$$

The Lagrangian (see section Analytical Mechanics page 3155) of the spinning top is deceptively simple as given then by:

$$L = \frac{1}{2} I_0 \left(\sin^2(\theta)\dot{\phi}^2 + \dot{\theta}^2 \right) + \frac{1}{2} I_\phi (\cos(\theta)\dot{\phi} + \dot{\gamma})^2 - mgR_G \cos(\theta) \tag{9.3.483}$$

We see that the Lagrangian does not depend explicitly on the variables ψ, ϕ or t. As a consequence, the angular momenta p_ϕ and p_ψ and the total energy E are invariant (i.e. conserved).

Let us recall that in the section of Analytical Mechanics we have proved that for a non-conservative force (that is not derived from a potential) we have:

$$\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i}=F_i \tag{9.3.484}$$

Or equivalently:

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L(q_i,\dot{q}_i,t)}{\partial \dot{q}_i}-\frac{\partial L(q_i,\dot{q}_i,t)}{\partial q_i}=F_i \tag{9.3.485}$$

Therefore to simplify the development we consider the potential gravitational force as a non-conservative force (this doesn't change the result anyway but its more easy to introduce it in this way to students or most readers):

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\phi}}-\frac{\partial L}{\partial \phi}&=0\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\theta}}-\frac{\partial L}{\partial \theta}&=mgR_G\cos(\theta)\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\gamma}}-\frac{\partial L}{\partial \gamma}&=0\end{aligned} \tag{9.3.486}$$

And looking to our Lagrangian we see that it simplifies automatically to:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\phi}}&=0\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\theta}}-\frac{\partial L}{\partial \theta}&=mgR_G\cos(\theta)\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\gamma}}&=0\end{aligned} \tag{9.3.487}$$

So let us focus on what seem the easiest to handle, that is:

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\phi}}&=0\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\gamma}}&=0\end{aligned} \tag{9.3.488}$$

It follows immediately:

$$\begin{aligned}\frac{\partial L}{\partial \dot{\phi}}&=c_1^{te}\\ \frac{\partial L}{\partial \dot{\gamma}}&=c_2^{te}\end{aligned} \tag{9.3.489}$$

But as we have seen in the section of Analytical Mechanics:

$$\begin{aligned}\frac{\partial L}{\partial \dot{\phi}}&=p_\phi=c_1^{te}\\ \frac{\partial L}{\partial \dot{\gamma}}&=p_\gamma=c_2^{te}\end{aligned} \tag{9.3.490}$$

where p_ϕ and p_γ are the canonical momentum.

Thus explicitly:

$$\begin{aligned}\frac{\partial L}{\partial \dot{\phi}}&=p_\phi=I_0\sin^2(\theta)\dot{\phi}+I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})\cos(\theta)=c_1^{te}\\ \frac{\partial L}{\partial \dot{\gamma}}&=p_\gamma=I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})=c_2^{te}\end{aligned} \tag{9.3.491}$$

Something important to notice is that since:

$$p_\gamma=I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})=c_2^{te} \tag{9.3.492}$$

and as we have obviously $I_\phi=c^{te}$ we get immediately:

$$\cos(\theta)\dot{\phi}+\dot{\gamma}=c_2^{te} \tag{9.3.493}$$

And it is normally obvious that this corresponds therefore to the rotation speed Ω of the spinning top on itself such that:

$$p_\gamma=I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})=I_\phi\Omega=c_2^{te} \tag{9.3.494}$$

The values p_ϕ,p_γ are therefore constants of motions and, as we will see it below, are therefore indispensable quantities for deriving other aspect of the top's motion such as precession and nutation.

Now we consider that the reader is familiar with the gyroscope's slow circling behaviour as int apparently defies gravity in its odd leaning without falling over. This is as we know "precession" trough the azimuthal angle γ. For the moment we will ignore nutation $\dot{\theta}=0$ and focus on the leaning angle θ, assumed constant, and the rate of precession $\dot{\gamma}$.

We shall use the energy method to derive the precession rate. This entails finding a point where the total system energy is stationary with respect to the angle θ, i.e.:

$$\frac{\partial E_{\text{tot}}}{\partial \theta}=0 \tag{9.3.495}$$

We can do this because E_{tot} is a conserved quantity set by the initial conditions. The energy must be a "stationary" or extreme value equal to the total system energy. Any deviation in θ from the correct value represents an error in the solution that pushes away from stationary value. This provides us with a handy mathematical trick for finding important physical properties of the system.

Since we ignore for now nutation (only steady precession is assumed), we eliminate the variables $\dot{\phi}$ and $\dot{\gamma}$ in E_{tot} by putting E_{tot} in term of the invariants p_ϕ and p_γ. We get (don't forget that for now we put $\dot{\theta}=0$!):

$$\begin{aligned}E_{\text{tot}}&=\frac{1}{2}I_0\left(\sin^2(\theta)\dot{\phi}^2+\dot{\theta}^2\right)+\frac{1}{2}I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})^2+mgR_G\cos(\theta)\\&=\frac{1}{2}I_0\sin^2(\theta)\dot{\phi}^2+\frac{1}{2}I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})^2+mgR_G\cos(\theta)\\&=\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+\frac{p_\gamma^2}{2I_\phi}+mgR_G\cos(\theta)\end{aligned}\tag{9.3.496}$$

Indeed as for the first term, this is not obvious! Let us check it:

$$\begin{aligned}\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}&=\frac{((I_0\sin^2(\theta)\dot{\phi}+I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})\cos(\theta))-(I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma}))\cos(\theta))^2}{2I_0\sin^2(\theta)}\\&=\frac{(I_0\sin^2(\theta)\dot{\phi})^2}{2I_0\sin^2(\theta)}=\frac{I_0^2\sin^4(\theta)\dot{\phi}^2}{2I_0\sin^2(\theta)}=\frac{1}{2}I_0\sin^2(\theta)\dot{\phi}^2\end{aligned}\tag{9.3.497}$$

Taking the derivative of E_{tot} with respect to the elevation angle θ yields:

$$\begin{aligned}\frac{\partial E_{\text{tot}}}{\partial\theta}&=\frac{\partial}{\partial\theta}\left(\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+\frac{p_\gamma^2}{2I_\phi}+mgR_G\cos(\theta)\right)=\frac{\partial}{\partial\theta}\left(\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+mgR_G\cos(\theta)\right)\\&=\frac{\partial}{\partial\theta}\left(\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}\right)-mgR_G\sin(\theta)\\&=\frac{2(p_\phi-p_\gamma\cos(\theta))p_\gamma\sin(\theta)}{2I_0\sin^2(\theta)}+\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^3(\theta)}(-2\cos(\theta))-mgR_G\sin(\theta)\\&=\frac{(p_\phi-p_\gamma\cos(\theta))p_\gamma\sin(\theta)}{I_0\sin^2(\theta)}-\frac{\cos(\theta)(p_\phi-p_\gamma\cos(\theta))^2}{I_0\sin^3(\theta)}-mgR_G\sin(\theta)\\&=\frac{(p_\phi-p_\gamma\cos(\theta))p_\gamma\sin^2(\theta)-\sin(\theta)\cos(\theta)(p_\phi-p_\gamma\cos(\theta))^2}{I_0\sin^4(\theta)}-mgR_G\sin(\theta)=0\end{aligned}\tag{9.3.498}$$

The solution of the above equation for θ yields the angle at which the gyroscope will lean given the speed of rotation of the wheel. The angle θ is found obviously by solving it for the roots in terms of the invariant quantities.

The precession rate is found by reorganizing:

$$p_\phi=I_0\sin^2(\theta)\dot{\phi}+I_\phi(\cos(\theta)\dot{\phi}+\dot{\gamma})\cos(\theta)\tag{9.3.499}$$

Therefore:

$$p_\phi=I_0\sin^2(\theta)\dot{\phi}+p_\gamma\cos(\theta)\tag{9.3.500}$$

Hence:

$$\dot{\phi}=\frac{p_\phi-p_\gamma\cos(\theta)}{I_0\sin^2(\theta)}\tag{9.3.501}$$

So now we can rewrite:

$$\frac{(p_\phi - p_\gamma\cos(\theta))p_\gamma\sin^2(\theta) - \sin(\theta)\cos(\theta)(p_\phi - p_\gamma\cos(\theta))^2}{I_0\sin^4(\theta)} - mgR_G\sin(\theta) = 0 \tag{9.3.502}$$

We multiply the both sides by:

$$-\frac{I_0\sin(\theta)}{p_\gamma} \tag{9.3.503}$$

So we get:

$$-\frac{(p_\phi - p_\gamma\cos(\theta))p_\gamma\sin^2(\theta) - \sin(\theta)\cos(\theta)(p_\phi - p_\gamma\cos(\theta))^2}{p_\gamma\sin^3(\theta)} + \frac{mgR_GI_0\sin^2(\theta)}{p_\gamma} = 0 \tag{9.3.504}$$

After simplification and rearranging we get the following polynomial equation in $(p_\phi - p_\gamma\cos(\theta))$ to solve:

$$\frac{\cos(\theta)}{p_\gamma\sin^2(\theta)}(p_\phi - p_\gamma\cos(\theta))^2 - (p_\phi - p_\gamma\cos(\theta)) + \frac{mgR_GI_0\sin^2(\theta)}{p_\gamma} = 0 \tag{9.3.505}$$

Using the quadratic formula to solve for the roots of this equation, we have (see section Calculus page 1383):

$$p_\phi - p_\gamma\cos(\theta) = \frac{1 \pm \sqrt{1 - 4\dfrac{\cos(\theta)}{p_\gamma\sin^2(\theta)}\dfrac{mgR_GI_0\sin^2(\theta)}{p_\gamma}}}{2\dfrac{\cos(\theta)}{p_\gamma\sin^2(\theta)}} = \frac{p_\gamma\sin^2(\theta)}{2\cos(\theta)}\left(1 \pm \sqrt{1 - \frac{4mgR_GI_0\cos(\theta)}{p_\gamma^2}}\right) \tag{9.3.506}$$

Using now:

$$\dot{\phi} = \frac{p_\phi - p_\gamma\cos(\theta)}{I_0\sin^2(\theta)} \tag{9.3.507}$$

we get:

$$\dot{\phi} = \frac{p_\gamma}{2I_0\cos(\theta)}\left(1 \pm \sqrt{1 - \frac{4mgR_GI_0\cos(\theta)}{p_\gamma^2}}\right) \tag{9.3.508}$$

Notice that if:

$$|p_\gamma| < \sqrt{4mgR_GI_0\cos(\theta)} \tag{9.3.509}$$

that is to say:

$$\Omega < \frac{\sqrt{4mgR_GI_0\cos(\theta)}}{I_\phi} \tag{9.3.510}$$

there is no well defined uniform precession.

The quadratic equation produces two solutions: the so-named "fast precession" and the "slow precession" solutions.

If the rotation speed of the heavy wheel is large (i.e. $p_\gamma \gg \sqrt{4mgR_G\cos(\theta)}$, the fast precession rate is:

$$\dot{\phi}_{\text{fast}} \cong \frac{p_\gamma}{2I_0\cos(\theta)} = \frac{I_\phi \Omega}{I_0\cos(\theta)} \quad (9.3.511)$$

Or if we take again the notations of our first approach with the symmetric weighing gyroscope:

$$\boxed{\Omega_{\text{fast}} \cong \frac{J\omega}{I_0\cos(\theta)}} \quad (9.3.512)$$

So we see that the gravitational force and the weight does not appear anymore so we are far from the result we get previously with the "classic approach".

The slow precession rate is found by using the small argument approximation for $\sqrt{1-x}$ as proved in the section of Sequences and Series (Maclaurin series page 1696):

$$\sqrt{1-x} \cong 1 - \frac{1}{2}x \quad (9.3.513)$$

Hence we find that:

$$\dot{\phi}_{\text{slow}} \cong \frac{mgR_G}{p_\gamma} = \frac{mgR_G}{I_\phi \Omega} \quad (9.3.514)$$

Or if we take again the notations of our first approach with the symmetric weighing gyroscope:

$$\boxed{\Omega_{\text{slow}} \cong \frac{mgR_G}{J\omega}} \quad (9.3.515)$$

So we fall back on exactly the same result!!!!

Once again it is interesting that the slow precession rate does not depend on the "leaning angle θ". The gyroscope will precess at a rate solely based on the wheel speed, stem length and the gravitational pull[15] on the center of mass of the gyroscope. The slow precession rate is the one most commonly observed experimentally as we already know.

Now that we have an expression for the precession rate, by using again:

$$\dot{\phi} = \frac{p_\phi - p_\gamma\cos(\theta)}{I_0\sin^2(\theta)} \quad (9.3.516)$$

That is:

$$p_\phi - p_\gamma\cos(\theta) - \dot{\phi}I_0\sin^2(\theta) = 0 \quad (9.3.517)$$

Using trigonometric identities:

$$p_\phi - p_\gamma\cos(\theta) - \dot{\phi}I_0(1-\cos^2(\theta)) = 0 \quad (9.3.518)$$

---

[15] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

After rearranging:

$$\dot{\phi}I_0\cos^2(\theta)-p_\gamma\cos(\theta)+(p_\phi-\dot{\phi}I_0)=0 \tag{9.3.519}$$

Or:

$$-\dot{\phi}I_0\cos^2(\theta)+p_\gamma\cos(\theta)+(\dot{\phi}I_0-p_\phi)=0 \tag{9.3.520}$$

Using the "slow" precession rate, i.e. $\dot{\phi}=mgR_G/p_\gamma$ and the quadratic equation to solve for $\cos(\theta)$, we see that:

$$\begin{aligned}\cos(\theta)&=\frac{-p_\gamma\pm\sqrt{p_\gamma^2+4I_0\dot{\phi}\left(I_0\dot{\phi}-p_\phi\right)}}{-2I_0\dot{\phi}}=\frac{-p_\gamma\pm\sqrt{p_\gamma^2+4I_0\dfrac{mgR_G}{p_\gamma}\left(I_0\dfrac{mgR_G}{p_\gamma}-p_\phi\right)}}{-2I_0\dfrac{mgR_G}{p_\gamma}}\\&=\frac{p_\gamma}{2I_0mgR_G}\left(p_\gamma\pm\sqrt{p_\gamma^2+4I_0\frac{mgR_G}{p_\gamma}\left(I_0\frac{mgR_G}{p_\gamma}-p_\phi\right)}\right)\\&=\frac{p_\gamma^2}{2I_0mgR_G}\left(1\pm\sqrt{1+4I_0\frac{mgR_G}{p_\gamma^3}\left(I_0\frac{mgR_G}{p_\gamma}-p_\phi\right)}\right)\\&=\frac{p_\gamma^2}{2I_0mgR_G}\left(1\pm\sqrt{1+4I_0\frac{mgR_G}{p_\gamma^2}\left(\frac{I_0mgR_G/p_\gamma-p_\phi}{p_\gamma}\right)}\right)\end{aligned} \tag{9.3.521}$$

Only the solution with the minus sign gives us a meaningful solution, because $\cos(\theta)$ can only take values between -1 and 1. Therefore:

$$\cos(\theta)=\frac{p_\gamma^2}{2I_0mgR_G}\left(1-\sqrt{1+4I_0\frac{mgR_G}{p_\gamma^2}\left(\frac{I_0mgR_G/p_\gamma-p_\phi}{p_\gamma}\right)}\right) \tag{9.3.522}$$

Moreover, if $p_\gamma^2\gg I_0mgR_G$,we can use the small argument approximation for the square-root, which gives us:

$$\begin{aligned}&\sqrt{1-\left(-4I_0\frac{mgR_G}{p_\gamma}\right)\left(\frac{I_0mgR_G/p_\gamma-p_\phi}{p_\gamma^2}\right)}\cong\sqrt{1-\left(-4I_0\frac{mgR_G}{p_\gamma^2}\right)\left(-\frac{p_\phi}{p_\gamma}\right)}\\&=\sqrt{1-4I_0\frac{mgR_Gp_\phi}{p_\gamma^3}}\cong 1-\frac{1}{2}4I_0\frac{mgR_Gp_\phi}{p_\gamma^3}=1-2I_0\frac{mgR_Gp_\phi}{p_\gamma^3}\end{aligned} \tag{9.3.523}$$

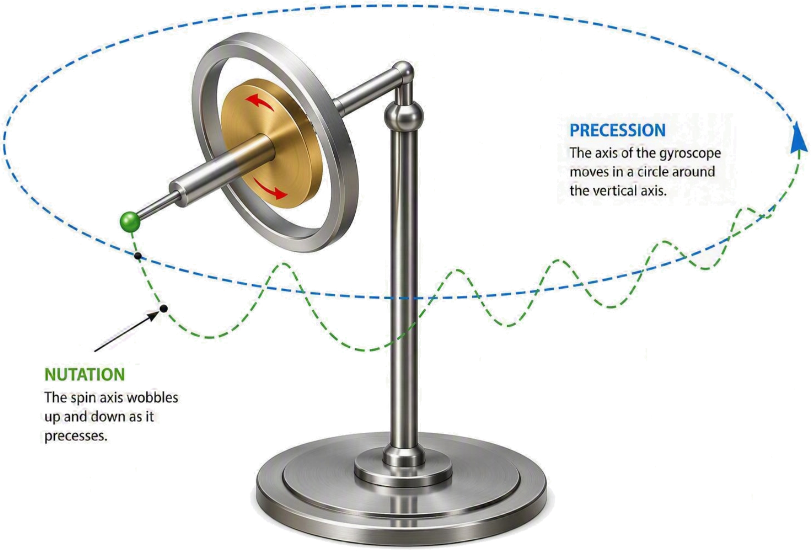
Therefore:

$$\cos(\theta)=\frac{p_\gamma^2}{2I_0mgR_G}\left(2I_0\frac{mgR_Gp_\phi}{p_\gamma^3}\right)=\frac{p_\phi}{p_\gamma} \tag{9.3.524}$$

Hence:

$$\boxed{\theta_{\text{lean}}\cong\arccos\left(\frac{p_\phi}{p_\gamma}\right)} \tag{9.3.525}$$

Now for the nutation who's typical movement is represented in the figure below:



PRECESSION
The axis of the gyroscope moves in a circle around the vertical axis.
NUTATION
The spin axis wobbles up and down as it precesses.

Figure 9.65: **Spinning top with precession AND nutation movement**

don't forget that we have determined for $\dot{\theta}$:

$$E_{\text{tot}}=\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+\frac{p_\gamma^2}{2I_\phi}+mgR_G\cos(\theta) \tag{9.3.526}$$

Re-including the kinetic energy of θ-directed motion (nutation), we have:

$$E_{\text{tot}}=\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+\frac{p_\gamma^2}{2I_\phi}+\frac{1}{2}I_0\dot{\theta}^2+mgR_G\cos(\theta) \tag{9.3.527}$$

A "potential energy" function that provides a "restoring force" can be taken from the above relation as:

$$V(\theta)=\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}+\frac{p_\gamma^2}{2I_\phi}+mgR_G\cos(\theta) \tag{9.3.528}$$

Therefore:

$$E_{\text{tot}}-V(\theta)=\frac{1}{2}I_0\dot{\theta}^2 \tag{9.3.529}$$

Hence:

$$\dot{\theta}=\sqrt{\frac{2}{I_0}(E-V(\theta))} \tag{9.3.530}$$

The extreme values of θ can be found by solving the above relation for the roots of $E_{\text{tot}}-V(\theta)$ in θ (these are the points in θ where $\dot{\theta}$ vanishes; i.e. the nutation angle extremes and therefore its variation $\Delta\theta=\theta_{\text{max}}-\theta_{\text{min}}$):

$$E_{\text{tot}}-V(\theta)=E_{\text{tot}}-\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0\sin^2(\theta)}-\frac{p_\gamma^2}{2I_\phi}-mgR_G\cos(\theta)=0 \tag{9.3.531}$$

That is:

$$E_{\text{tot}}-\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0(1-\cos^2(\theta))}-\frac{p_\gamma^2}{2I_\phi}-mgR_G\cos(\theta)=0 \tag{9.3.532}$$

Or that we can rewrite:

$$E_{\text{tot}}(1-\cos^2(\theta))-\frac{(p_\phi-p_\gamma\cos(\theta))^2}{2I_0}-\frac{p_\gamma^2}{2I_\phi}(1-\cos^2(\theta))-mgR_G\cos(\theta)(1-\cos^2(\theta))=0 \tag{9.3.533}$$

and also:

$$2I_0E_{\text{tot}}(1-\cos^2(\theta))-(p_\phi-p_\gamma\cos(\theta))^2-\frac{2I_0p_\gamma^2}{2I_\phi}(1-\cos^2(\theta))-2I_0mgR_G\cos(\theta)(1-\cos^2(\theta))=0 \tag{9.3.534}$$

Grouping, we get:

$$\begin{aligned}2I_0mgR_G\cos^3(\theta)+\left(2I_0p_\phi p_\gamma^2+\frac{2I_0p_\gamma^2}{2I_\phi}-2I_0E_{\text{tot}}\right)\cos^2(\theta)+(4I_0p_\phi p_\gamma-2I_0mgR_G)\cos(\theta)\\+\left(2I_0E_{\text{tot}}-2I_0p_\phi^2-\frac{2I_0p_\gamma^2}{2I_\phi}\right)=0\end{aligned} \tag{9.3.535}$$

Factorizing:

$$\begin{aligned}2I_0mgR_G\cos^3(\theta)+\left(p_\gamma^2+\frac{2I_0p_\gamma^2}{2I_\phi}-2I_0E_{\text{tot}}\right)\cos^2(\theta)+(2p_\phi p_\gamma-2I_0mgR_G)\cos(\theta)\\+\left(2I_0E_{\text{tot}}-p_\phi^2-\frac{2I_0p_\gamma^2}{2I_\phi}\right)=0\end{aligned} \tag{9.3.536}$$

Reorganizing:

$$\begin{aligned}2I_0mgR_G\cos^3(\theta)-\left(2I_0E_{\text{tot}}-\frac{2I_0p_\gamma^2}{2I_\phi}-p_\gamma^2\right)\cos^2(\theta)+(2p_\phi p_\gamma-2I_0mgR_G)\cos(\theta)\\+\left(2I_0E_{\text{tot}}-\frac{2I_0p_\gamma^2}{2I_\phi}-p_\phi^2\right)=0\end{aligned} \tag{9.3.537}$$

Factorizing:

$$\begin{aligned}2I_0mgR_G\cos^3(\theta)-\left\{2I_0\left(E_{\text{tot}}-\frac{p_\gamma^2}{2I_\phi}\right)-p_\gamma^2\right\}\cos^2(\theta)+(2p_\phi p_\gamma-2I_0mgR_G)\cos(\theta)\\+\left\{2I_0\left(E_{\text{tot}}-\frac{p_\gamma^2}{2I_\phi}\right)-p_\phi^2\right\}=0\end{aligned} \tag{9.3.538}$$

Setting $x=\cos(\theta)$ we have:

$$2I_0mgR_Gx^3-\left\{2I_0\left(E_{\text{tot}}-\frac{p_\gamma^2}{2I_\phi}\right)-p_\gamma^2\right\}x^2+2\left(p_\phi p_\gamma-I_0mgR_G\right)x+\left\{2I_0\left(E_{\text{tot}}-\frac{p_\gamma^2}{2I_\phi}\right)-p_\phi^2\right\}=0 \tag{9.3.539}$$

By solving for x, we find one or two roots between -1 and $+1$ and another non-physical root ($|x|>1$). The two physically meaningful roots will yield the span of angles of the nutation. If the roots are equivalent, there is no nutation; only smooth precession.

We will now write the latter relation as in our study of third degree polynomial equations in the section Calculus (see page 1390):

$$ax^3+bx^2+cx+d=0 \tag{9.3.540}$$

with:

$$\begin{aligned}a&=2I_0mgR_G\\ b&=2I_0\left(\frac{p_\gamma^2}{2I_\phi}-E_{\text{tot}}\right)+p_\gamma^2\\ c&=2\left(p_\phi p_\gamma-I_0mgR_G\right)\\ d&=2I_0\left(E_{\text{tot}}-\frac{p_\gamma^2}{2I_\phi}\right)-p_\phi^2\end{aligned} \tag{9.3.541}$$

We use now the trick used in the section Calculus. First we know we have to put:

$$\begin{cases}x=X-\dfrac{b}{3a}\\ p=\dfrac{c}{a}-\dfrac{b^2}{3a^2}\\ q=\dfrac{2b^3}{27a^3}-\dfrac{cb}{3a^2}+\dfrac{d}{a}\end{cases} \tag{9.3.542}$$

So we get the following simplified polynomial (but the explicit expression of the coefficients are quite long...):

$$P=X^3+pX+q \tag{9.3.543}$$

After, as we have proved it in the section Calculus we must calculate the following discriminant:

$$\Delta=q^2+4\frac{p^3}{27} \tag{9.3.544}$$

and determine it's sign.

Caution!! As far as we know, none of the relations derived earlier for the nutation or lean angle applies for a celestial body like Earth or any other planet. A numerical application leads to results that doesn't make any sense in a magnitude of 10^{20}!

Figure 9.66: **Mechanical airplane gyroscope principle**

Forces associated with the rotation of Earth cause the planet to be slightly oblate, displaying a bulge at the equator (see section Astronomy page 5300). The Moon's gravity primarily, and to a lesser degree the Sun's gravity, act on Earth's oblateness to move the axis perpendicular to the plane of Earth's orbit. However, due to gyroscopic action, Earth's poles do not "right themselves" to a position perpendicular to the orbital plane. Instead, they precess at 90 degrees to the force applied. This luni-solar precession effect causes the axis of Earth to describe a circle having a 23.4 degree radius relative to a fixed point in space over about $26,000$ years, a slow wobble reminiscent of the axis of a spinning top swinging around before it falls over.

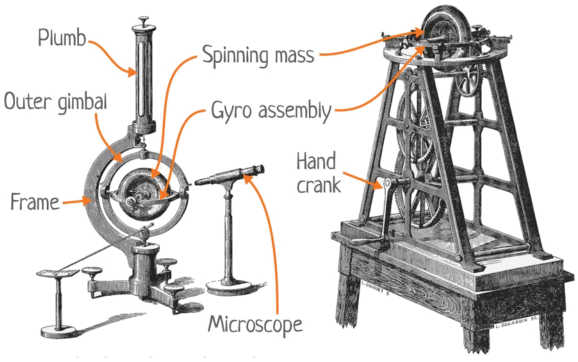
Figure 9.67: Mouvement de nutation de la Terre

However, the Earth is not the only planet having precessional and nutational motions. Mars in particular is also rapidly rotating, has an equatorial bulge, and its mean orientation is tilted with respect to the ecliptic (the obliquity of Mars is about 25°). Therefore Mars also changes its orientation in space. All the giants planets (Jupiter, Saturn, Uranus, Neptune) also have a nutation movement!

Like Foucault used his pendulum to prove the rotation of the Earth, in 1185 (holocene calendar) he used the Gyroscope to demonstrate again Earth's rotation:



Plumb
Outer gimbal
Frame
Spinning mass
Gyro assembly
Hand
crank
Microscope

Figure 9.68: Foucault gyroscope (author: L. Dujardin)

He used as visible in the illustration above a hand crank with four stages of gears to spin up the gyroscope to the initial speed of $1,200$ rpm, allowing it to persist for ten minutes. This was sufficient to observe the precession from Earth's rotation using a microscope!

Some quite complex mathematical models (maybe one day we will detail them in this textbook) give the possibility to compute the precession-nutation period for planets. The most well-known model (Kinoshita theory) gives for example the following theoretical numerical values for the precession period T_E (in million years) considering only the torque of the Sun (actually a G2V-type star, aka yellow dwarf) but not of the planets satellites:

Planet	Period $T_P(My)$	T_P/T_E
Earth	0.0258	1
Jupiter	1.4960	57.966
Saturn	7.2564	281.26
Uranus	1136.84	44063.6
Neptune	753.49	29204.9

Table 9.18: **Theoretical precession periods of some giant planets**

Here is a nice visual summary of the lean angle (i.e. tilt angle) and rotation periods of some well known celestial bodies as in the 121st century (holocene calendar):

9.3.8.2.4 König's kinetic and angular momentum theorems

In kinetics, "König's theorems" or "König's decompositions" is a couple of mathematical relations derived by Johann Samuel König that assists with the calculation of kinetic energy and angular momentum of bodies and systems of particles.

These theorems expresses the kinetic energy and angular momentum of a system of particles in terms of the velocities of the individual particles. Specifically, they states that the kinetic energy and angular moment of a system of particles is the sum of the kinetic energy/angular momentum associated to the movement of the center of mass and the kinetic energy/angular momentum associated to the movement of the particles relative to the center of mass.

As this result is quite obvious many teachers and books don't speak about these theorems and therefore don't prove them. I have put these theorem here only as a tribute to one of the teacher of my Engineering School but for not other reason as we will never mention them directly in any other section or chapter of this textbook (again because it's simply obvious!).

OK. Let us start! So don't forget we have seen so far how to calculate the angular momentum or kinetic energy of a dynamic system compared to a single reference frame (either Galilean or centroid).

The König's theorems give respectively the angular momentum and the total kinetic energy of a dynamic system with respect to a Galilean reference frame R_{gal} or centroid one R_{cen}.

9.3.8.2.4.1 First König's Theorem (König's angular momentum theorem)

Let us use the angular momentum of a body of mass M to prove this theorem (the example being always easily extendable to a discrete or continuous dynamic system of matter).

Let us express the angular momentum $\vec{b}$ of an element m_i of the solid body with respect to the origin O of the Galilean R_{gal} reference frame (denoted thereafter $/\text{O},R$):

$$\vec{b}_{/\text{O},R}=\sum_i m_i\overrightarrow{\text{O}A_i}\times\vec{v}_{i/R'} \tag{9.3.545}$$

Let us express the angular momentum in R_{cen} relatively to its center of mass G (denoted thereafter $/G,R'$):

$$\vec{b}_{/G,R'}=\sum_i m_i\overrightarrow{GA_i}\times\vec{v}_{i/R'} \tag{9.3.546}$$

The reference frame R_{cen} being in translation relatively to R_{gal}, we have:

$$\vec{v}_{i/R}=\vec{v}_{i/R'}+\vec{v}_{G/R} \tag{9.3.547}$$

Without forgetting that:

$$\overrightarrow{\text{O}A_i}=\overrightarrow{\text{O}G}+\overrightarrow{GA_i} \tag{9.3.548}$$

that we insert in the expression of the angular momentum relatively to R_{gal}:

$$\vec{b}_{/\text{O},R}=\sum_i m_i\overrightarrow{\text{O}A_i}\times\vec{v}_{i/R}=\sum_i m_i\left(\overrightarrow{\text{O}G}+\overrightarrow{GA_i}\right)\times\left(\vec{v}_{i/R'}+\vec{v}_{G/R}\right) \tag{9.3.549}$$

From the property of distributivity over addition of the cross product, we have:

$$\vec{b}_{/\text{O},R}=\sum_i m_i\overrightarrow{\text{O}G}\times\vec{v}_{i/R'}+\sum_i m_i\overrightarrow{GA_i}\times\vec{v}_{i/R'}+\sum_i m_i\overrightarrow{\text{O}G}\times\vec{v}_{G/R}+\sum_i m_i\overrightarrow{GA_i}\times\vec{v}_{G/R} \tag{9.3.550}$$

Let us now study the value that take each of the four terms of the previous relation. We have proved by definition of the center of mass that (in a non-relativistic framework):

$$\frac{\sum\limits_i m_i\overrightarrow{GA_i}}{\sum\limits_i}=\vec{0}\Rightarrow\sum_i m_i\overrightarrow{GA_i}=\vec{0}\Rightarrow\frac{\mathrm{d}}{\mathrm{d}t}\sum_i\overrightarrow{GA_i}=\sum_i m_i\left(\frac{\mathrm{d}}{\mathrm{d}t}\overrightarrow{GA_i}\right)=\sum_i m_i\vec{v}_{i/R'}=\vec{0} \tag{9.3.551}$$

hence:

$$\sum_i m_i\overrightarrow{\mathrm{O}G}\times\vec{v}_{i/R'}=\overrightarrow{\mathrm{O}G}\times\left(\sum_i m_i\vec{v}_{i/R'}\right)=\vec{0} \tag{9.3.552}$$

So it comes:

$$\begin{aligned}\vec{b}_{/\mathrm{O},R}&=\sum_i m_i\overrightarrow{GA_i}\times\vec{v}_{i/R'}+\sum_i m_i\overrightarrow{\mathrm{O}G}\times\vec{v}_{G/R}=\vec{b}_{/G,R'}+\overrightarrow{\mathrm{O}G}\times\vec{v}_{G/R}\sum_i m_i\\&=\vec{b}_{/G,R'}+M\overrightarrow{\mathrm{O}G}\times\vec{v}_{G/R}\end{aligned} \tag{9.3.553}$$

Therefore we have finally:

$$\boxed{\vec{b}_{/\mathrm{O},R}=\vec{b}_{/G,R'}+M\overrightarrow{\mathrm{O}G}\times\vec{v}_{G/R}} \tag{9.3.554}$$

This theorem that relates to a fixed point allows an easier application of the theorem of angular momentum.

9.3.8.2.4.2 Second König's Theorem (König's kinetic energy theorem)

To prove this theorem let us use the kinetic energy of a mass M (the example is still easily expandable to a discrete or continuous dynamic system of material).

Let us express the kinetic energy of an element m_i of the solid body with respect to the origin O of the Galilean reference frame R_{gal} (denoted thereafter $/\mathrm{O},R$):

$$E_{c/\mathrm{O},R}=\frac{1}{2}\sum_i m_i v_{i/R}^2 \tag{9.3.555}$$

Let us express the kinetic energy in R_{cent} relatively to its center of mass G (denoted thereafter $/G,R'$):

$$E_{c/G,R'}=\frac{1}{2}\sum_i v_{i/R'}^2 \tag{9.3.556}$$

With same as above:

$$\vec{v}_{i/R}=\vec{v}_{i/R'}+\vec{v}_{G/R} \tag{9.3.557}$$

Therefore we have:

$$E_{c/\mathrm{O},R}=\frac{1}{2}\sum_i m_i\vec{v}_{i/R}^2=\frac{1}{2}\sum_i m_i\left(\vec{v}_{i/R'}+\vec{v}_{G/R}\right)^2 \tag{9.3.558}$$

Hence (the dot products of the vectors are implicit!!!):

$$\begin{aligned}E_{c/\text{O},R}&=\frac{1}{2}\sum_i m_i\vec{v}_{i/R'}^2+\frac{1}{2}\sum_i m_i\vec{v}_{G/R}^2+\frac{1}{2}\sum_i 2m_i\vec{v}_{i/R'}\vec{v}_{G/R}\\&=E_{c,G/R'}+\frac{1}{2}M\vec{v}_{G/R}^2+\vec{v}_{G/R}\sum_i\vec{v}_{i/R'}\end{aligned}\tag{9.3.559}$$

and as for the angular momentum, by the definition of the mass center, we have:

$$\sum_i m_i\vec{v}_{i/R'}=\vec{0}\tag{9.3.560}$$

Hence the second König's theorem:

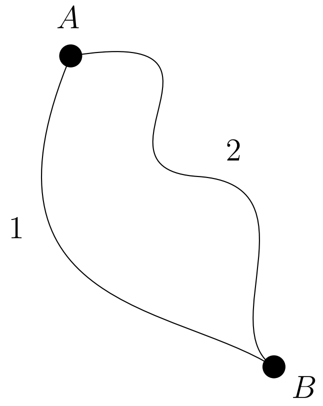
$$\boxed{E_{c/\text{O},R}=E_{c,G/R'}+\frac{1}{2}Mv_{G/R}^2}\tag{9.3.561}$$

9.3.8.3 Gravitational Potential Energy

Gravitational potential energy is energy an object possesses because of its position in a gravitational field. The most common use of gravitational potential energy is for an object near the surface of the Earth. The gravitational potential is also known as the "Newtonian potential" and is fundamental in the study of potential theory.

Since the zero of gravitational potential energy can be chosen at any point (like the choice of the zero of a coordinate system), the potential energy at a height h above that point is equal to the work which would be required to lift the object to that height with no net change in kinetic energy. Since the force required to lift it is equal to its weight, it follows that the gravitational potential energy is equal to its weight mg times the height h to which it is lifted mgh.

Let us first recall that if the work of the force $\vec{F}$ between points A and B is independent of the path taken, we say that this force derives from a potential energy or that force field is a "conservative field" (counter-example: in a motion with friction works necessarily depends on the chosen path). This independence from the path followed that if given two points A and B in space. There are several possible ways to join these two points. If we choose two random points we have:



- On the first path: $\displaystyle\int_A^B \vec{F}\circ \mathrm{d}\vec{r}_1$
- On the second path: $\displaystyle\int_A^B \vec{F}\circ \mathrm{d}\vec{r}_2$

If the field is conservative we have:

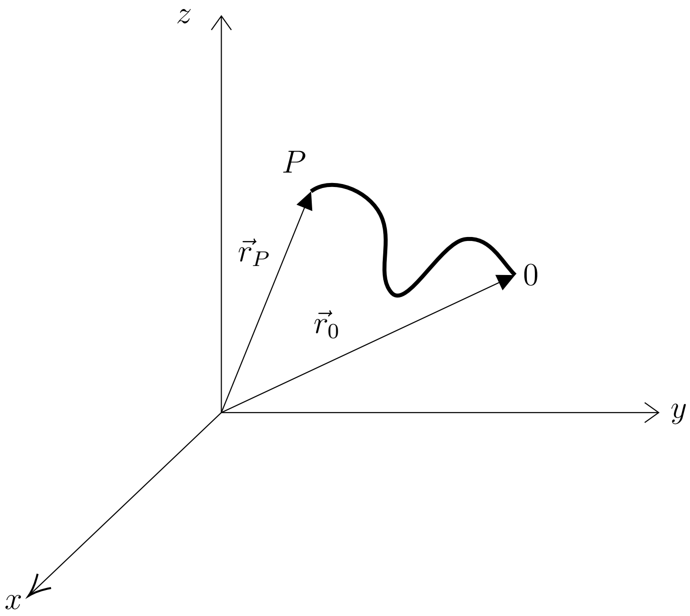
$$\int_A^B \vec{F}\circ \mathrm{d}\vec{r}_1=\int_A^B \vec{F}\circ \mathrm{d}\vec{r}_2=\int_A^B \vec{F}\circ \mathrm{d}\vec{r}=-\int_B^A \vec{F}\circ \mathrm{d}\vec{r} \tag{9.3.562}$$

or in other words that the total work on a closed path (go and come back) is zero. We notice that (see section Differential and Integral Calculus page 1583):

$$\oint \vec{F}\circ \mathrm{d}\vec{r}=0 \tag{9.3.563}$$

The work involved is therefore a function of the location only (E_p) that is to say, depending only on the starting point and ending point. Indeed, if the work depended on the path it would be possible to choose the most generous way when the system provides work and the most economical way when we bring him back to the initial state. So it would be a perpetual motion and the principle of conservation of energy forbids that (see section Thermodynamics page 3666)!

Let us then attach to each point P of the force field a value of the function E_p (a real number) corresponding to the work done by the force field when the mobile moves from one point P to 0, 0 being a reference point arbitrarily chosen:

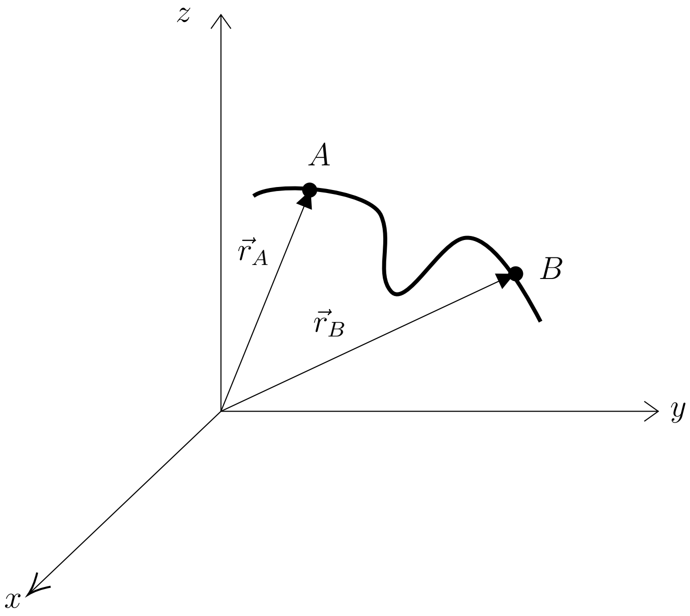


So by definition:

$$E_p(P)=\int_P^0 \vec{F}\circ \mathrm{d}\vec{r} \qquad (9.3.564)$$

with $E_p(0)=0$.

Generalizing this definition a little bit, we say that the work W done by a conservative force when moving from A to B:



is equal to the reduction of potential energy between A and B:

$$W_{A,B}=\int\limits_{A}\vec{F}\circ\mathrm{d}\vec{r}=-(E_p(B)-E_p(A)) \tag{9.3.565}$$

By definition E_p is the potential energy and is measured in Joules [J] as for the kinetic energy.

The above relation is used very often in its differential form is:

$$\boxed{\mathrm{d}W=-\mathrm{d}E_p} \tag{9.3.566}$$

There is also for recall a relation between energy and the gradient of the given force that simply follows from the definition of work:

$$\boxed{\vec{F}=-\vec{\nabla}\cdot E_p} \tag{9.3.567}$$

The most significant application in Classical Mechanics is the work of gravity and the gravitational potential energy near the surface of the Earth (or another planet!). It is therefore a special case where the force is constant...

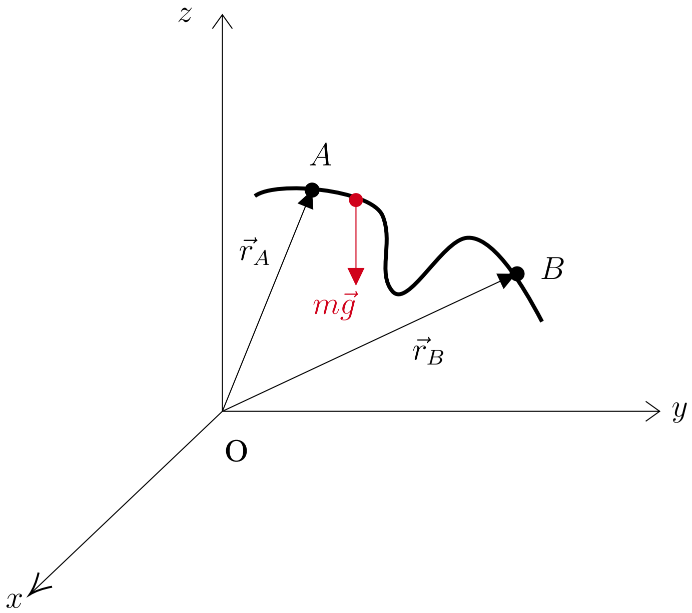


Figure 9.70: **Illustration of gravitational work between two points in constant force field**

Following the figure above given a point of mass m moving following any trajectory AB in a constant gravitational field force $\vec{g}$. The weight $m\vec{g}$ do then the following work:

$$W_{A,B}=\int_A^B \vec{F}\circ\mathrm{d}\vec{r}=\vec{F}\circ(\vec{r}_B-\vec{r}_A)=m\vec{g}\circ(\vec{r}_B-\vec{r}_A) \tag{9.3.568}$$

The difference z_A-z_B is the difference in elevation between points A and B. We notice well that the work does not depend on the path followed but only on the points of departure and arrival. If, conversely, we want to move the massive point from B to A, the work, then provided by an external element is:

$$W_{B,A}=-W_{A,B}=-mg(z_A-z_B) \tag{9.3.569}$$

which shows well that the total work on a closed path is zero is such a special case:

$$\oint \vec{F}\circ\mathrm{d}\vec{r}=0 \tag{9.3.570}$$

Comparing the relations:

$$W_{A,B}=-(E_P(B)-E_P(A)) \qquad \text{and} \qquad W_{A,B}=mg(z_A-z_B) \tag{9.3.571}$$

and identifying, we get for a constant gravitational field:

$$\boxed{E_p(z)=mgz} \tag{9.3.572}$$

which is the gravitational potential energy, z is the altitude of the mass m. We denote this simply this relation this relation under the form:

$$E_p=mgh \tag{9.3.573}$$

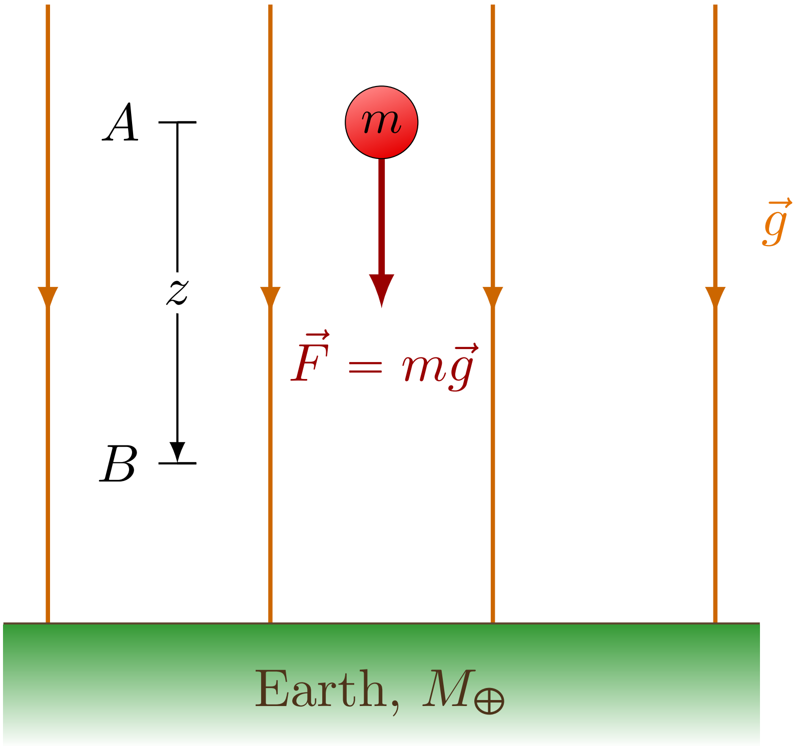

Figure 9.71: **Naive scenario of gravitational potential energy (author: Izaak Neutelings)**

Remark

The choice of the zero level of potential energy is often arbitrary; we set it ourselves for convenience depending on the situation. Only the differences of potential energy are generally interesting as we will see just below.

The previous relation is actually a useful expression near the Earth's surface (or any other planet). At a distance $r \gg R$ where R is the radius of the Earth, the gravitational force weakens and the approximation is no longer valid (if $r \ll R$ also anyway...).

To determine the correct relation, consider two masses m_1, m_2. The first is supposed at rest and fixed and the second is brought from infinity to a given distance from m_1 (the same reasoning applies to the electric field!!!!). The work $\mathrm{d}W$ of the gravitational force at any point being thus:

$$\mathrm{d}W = F\mathrm{d}x \tag{9.3.574}$$

and the potential energy of the system:

$$\mathrm{d}E_p = -\mathrm{d}W \tag{9.3.575}$$

Then:

$$\mathrm{d}E_p = -\mathrm{d}W = -F\mathrm{d}x = -G\frac{m_1m_2}{x^2}\mathrm{d}x \tag{9.3.576}$$

where just after integration (the potential energy in a point):

$$\boxed{E_p = G\frac{m_1m_2}{x}} \tag{9.3.577}$$

Let us see if this is consistent with $E_p = mgz$...:

Proof 9.8.2. At zero height of the planet surface $x=R$, we have:

$$E_p=-G\frac{m_1m_2}{R}=E_{0,p} \tag{9.3.578}$$

where the choice of the sign "$-$" depends only on the selected reference frame that is in this case in line with what is customary to take in schools.

We raise the object of $h\ll R$:

$$E_p(R+h)=-G\frac{m_1m_2}{R+h}=-Gm_1m_2\frac{1}{R+h}=-Gm_1m_2\frac{1}{R(1+h/R)}=-G\frac{m_1m_2}{R}\frac{1}{1+h/R} \tag{9.3.579}$$

We use now the rough approximation (see section Sequences and Series page 1696):

$$\frac{1}{1+x}\cong 1-x \tag{9.3.580}$$

valid when $x\ll 1$, hence:

$$E_p(R+h)\cong -G\frac{m_1m_2}{R}\left(1-\frac{h}{R}\right)=-G\frac{m_1m_2}{R}+G\frac{m_1m_2}{R^2}h=U_0-F_Gh=U_0+mgh \tag{9.3.581}$$

As at the surface of the Earth (or any other planet) we usually put in laboratories that $U_0=0$, we get well eventually:

$$E_p(h)\cong mgh \tag{9.3.582}$$

and we see that it is indeed a rough approximation.

■ Q.E.D.

Remark

We could apply the same development in the study of the Coulomb force and of the Electric field but until now we have never been put a laboratory to the surface of an electric charge... (sic!).

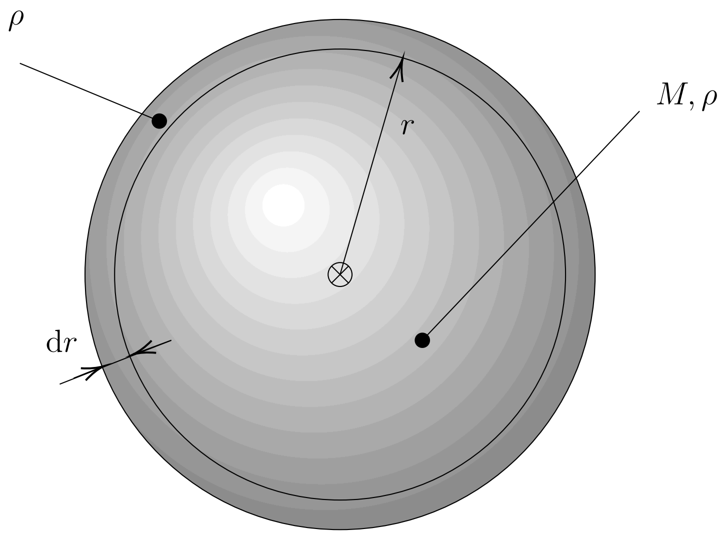
9.3.8.3.1 Gravitational Potential Energy of a Material Sphere

We will calculate here the potential energy of a material sphere. This style of exercise will be very useful in the section of Astrophysics (see page 5539) to determine the internal temperature of the stars and in the section about Cosmogony (see page 5878) to start the study of the Friedmann model.

The potential energy of the spherical ring of inner radius r and thickness $\mathrm{d}r$ is calculated as follows:

$$E_p=-\frac{GMm}{r} \tag{9.3.583}$$

Given a sphere of mass M, of mass density ρ and radius r surrounded by a spherical ring of inner radius r, of the same mass density ρ and thickness $\mathrm{d}r$:



The mass of the sphere of radius r and mass density ρ is equal as we know:

$$M=V\rho=\frac{4}{3}\pi r^3\rho \tag{9.3.584}$$

The mass of the ring surrounding the sphere of radius r, of thickness $\mathrm{d}r$ and mass density ρ is:

$$m=\mathrm{d}V\rho=4\pi r^2\mathrm{d}r\rho \tag{9.3.585}$$

By introducing the last two terms in the expression of the potential energy:

$$\mathrm{d}E_p=-\frac{G\left(\dfrac{4}{3}\pi r^3\rho\right)(4\pi r^2\rho\mathrm{d}r)}{r}=-\frac{1}{3}G(4\pi\rho)^2r^4\mathrm{d}r \tag{9.3.586}$$

By integrating the previous expression between 0 and R, this is equivalent to add successively a range of rings of thickness $\mathrm{d}r$ to get the whole sphere of radius R and therefore the potential energy of the whole sphere:

$$E_p=-\frac{1}{3}G(4\pi\rho)^2\int_0^R r^4\mathrm{d}r=-\frac{1}{3}G(4\pi\rho)^2\frac{R^5}{5} \tag{9.3.587}$$

Which can be written also:

$$E_p=-\frac{3}{5}G\left(\frac{4}{3}\pi\rho R^3\right)^2\frac{1}{R}=-\frac{3}{5}GM^2\frac{1}{R} \tag{9.3.588}$$

Thus finally:

$$\boxed{E_p=-\frac{3}{5}\frac{GM^2}{R}} \tag{9.3.589}$$

Exactly the same calculation can be done in electrostatics by replacing the gravitational constant G by the Coulomb constant k_e and the mass M by the total Electric charge Q. It is also a result we will reuse in the model of the liquid nuclear core (see section Nuclear Physics page 5141).

Remark

As the Newton law and Coulomb law are similar in shape, we get using exactly the same calculation for electrostatic in a condensed stable material:

$$E_p=\frac{3}{5}\frac{Q^2}{4\pi\epsilon_0 a} \tag{9.3.590}$$

It may seem useless to have such a result however... it is used a lot as basis of the study of "polarons". A polaron refers to the local distortion of a molecular structure or lattice caused by a charge carrier moving through a semiconductor, the charge carrier and its disturbed environment treated mathematically as a fermionic quasiparticles. It represents the combination of both the electron or hole and the displacement of atoms from their equilibrium position within the molecule or lattice. Polarons form easily in polarizable materials as excess charge carriers couple with ionic lattice vibrations, leading to localized lattice distortions.

9.3.8.3.2 Gravitational Effective potential

Definition (#445): The "effective potential" (also known as "effective potential energy") combines multiple, perhaps opposing, effects into a single potential. In its basic form, it is the sum of the 'opposing' centrifugal potential energy with the potential energy of a dynamical system. It may be used to determine the orbits of celestial objects (both Newtonian and relativistic as proved at page 5845) and to perform semi-classical atomic calculations (see section Quantum Chemistry page 6187), and often allows problems to be reduced to fewer dimensions.

Consider a particle of mass m orbiting a much heavier object of mass M. Assume Newtonian Mechanics, which is both classical and non-relativistic (the relativistic case based on General Relativity is treated in details in the section of General Relativity at page 5845). The conservation of energy E and angular momentum (see section Classical Mechanics page 3244) that we will denote here L instead of b to respect the traditions (...) give us two constants E and L (gravity being is a central force and thus not a torque which means that angular momentum is conserved), which have values (we expressed the speed in polar coordinates as proven in the section of Vector Calculus at page 1863):

$$\begin{gathered}E_{\text{tot}}=E_c+E_p=\frac{1}{2}mv^2-\frac{GmM}{r}=\frac{1}{2}m\left(\dot{r}^2+r^2\dot{\phi}^2\right)-\frac{GmM}{r}=\frac{1}{2}m\left(v_r^2+v_\phi^2\right)-\frac{GmM}{r}\\ L=mr^2\dot{\phi}\end{gathered} \tag{9.3.591}$$

when the motion of the larger mass is negligible. In these expressions:

- $\dot{r}$ is the derivative of r with respect to time,
- $\dot{\phi}$ is the angular velocity of mass m,
- G is the gravitational constant,
- E_{tot} is the total energy, and

- L is the angular momentum.

Only two variables are needed, since the motion occurs in a plane. Substituting the second expression into the first and rearranging gives:

$$m\dot{r}^2=2E_{\text{tot}}-\frac{L^2}{mr^2}+\frac{2GmM}{r}=2E_{\text{tot}}-\frac{1}{r^2}\left(\frac{L^2}{m}-2GmMr\right) \qquad (9.3.592)$$

That is denoted by tradition:

$$\frac{1}{2}m\dot{r}^2=E-U_{\text{eff}}(r) \qquad (9.3.593)$$

with by definition the "Gravitational non-relativistic effective potential" (as the previous relation has the shape of something like $E_c=E_{\text{tot}}-E_p$):

$$\boxed{U_{\text{eff}}(r):=\frac{L^2}{2mr^2}-\frac{GmM}{r}} \qquad (9.3.594)$$

The original two-variable problem has been reduced to a one-variable problem. For many applications the effective potential can be treated exactly like the potential energy of a one-dimensional system: for instance, an energy diagram using the effective potential determines turning points and locations of stable and unstable equilibria. A similar method may be used in other applications, for instance determining orbits in a general relativistic Schwarzschild metric.

Therefore an effective potential energy is not technically a potential energy but can still be used to obtain qualitative information about motion. So we can say that one introduces an effective potential when a physical effect whose origin is not a potential can be described adequately as if it simply gave rise to a potential!

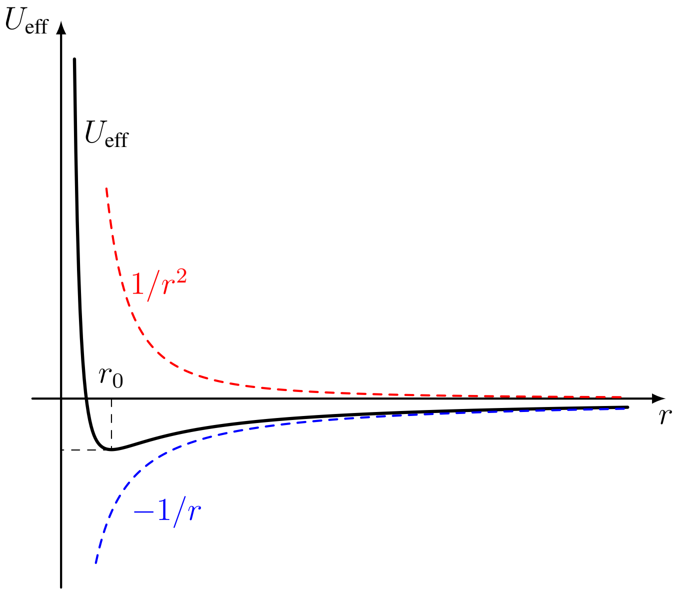


Figure 9.72: Graph of non-relativistic effective gravitational potential (author: Alexandros Tsagkaropoulos)

Given an angular momentum L, we can plot the non-relativistic gravitational effective potential as above and immediately see where the stable circular orbits are (the minima of the potential).

We can also qualitatively see how there is a barrier to approaching the object too closely (which makes sense - if we have angular momentum you wouldn't expect a head on collision).

Doing the same kind of plot for multiple values of L we see that the minimum position of the effective potential increases with angular momentum. Therefore, planets with higher angular momenta are farther from their stars.

9.3.8.4 Conservation of Total Mechanical Energy

Let us compare the relations:

$$W_{A,B} = -(E_p(B) - E_p(A)) = E_c(B) - E_c(A) \tag{9.3.595}$$

since it is the same work!

Which leads to:

$$E_p(A) - E_c(A) = E_c(B) - E_p(A) \tag{9.3.596}$$

sum of the two forms of energy at each point or also, considering any locations A and B, by rewriting the equation in a more general form:

$$\boxed{E_p + E_c = c^{te}} \tag{9.3.597}$$

Remark

We often name the total energy of a system "Hamiltonian of the system" as we have already study it in the section of Analytical Mechanics.

In the absence of friction of external force in the case of mechanical energy, we also write the variation such that:

$$\mathrm{d}E_p + \mathrm{d}E_c = 0 \tag{9.3.598}$$

An increase in kinetic energy therefore results in a decrease of potential energy (and vice versa) since the sum of the two remains constant.

Against-example: If there is friction, heat is released and then total mechanical energy is not constant! Also if the studied object is a rocket propulsed in space.

Furthermore let us come back on the relation:

$$\mathrm{d}W = -\mathrm{d}E_p \Leftrightarrow \mathrm{d}E_p = -\mathrm{d}W \tag{9.3.599}$$

and therefore:

$$\mathrm{d}E_p = -\mathrm{d}W = -\vec{F} \circ \mathrm{d}\vec{r} = -(F_x\mathrm{d}x + F_y\mathrm{d}y + F_z\mathrm{d}z) \tag{9.3.600}$$

On the other hand, E_p being a scalar function dependent on spatial coordinates, let us write its total differential:

$$\mathrm{d}E_p = \frac{\partial E_p}{\partial x}\mathrm{d}x + \frac{\partial E_p}{\partial y}\mathrm{d}y + \frac{\partial E_p}{\partial y}\mathrm{d}y \tag{9.3.601}$$

comparing with the previous equation and identifying term by term, we have:

$$\frac{\partial E_p}{\partial x}=-F_x \qquad \frac{\partial E_p}{\partial y}=-F_y \qquad \frac{\partial E_p}{\partial z}=-F_z \tag{9.3.602}$$

hence the sentence stating that the force derived from a potential energy if the work involved is independent of the followed path. If we express the force $\vec{F}$ in terms of unitary vectors, we get:

$$\vec{F}=F_x\vec{i}+F_y\vec{j}+F_z\vec{k}=-\left(\frac{\partial E_p}{\partial x}\vec{i}+\frac{\partial E_p}{\partial y}\vec{j}+\frac{\partial E_p}{\partial z}\vec{k}\right)=-\overrightarrow{\text{grad}}(E_p) \tag{9.3.603}$$

Finally, the claim (statement) that the force derived from a potential energy E_p can be summarized as:

$$\vec{F}=-\overrightarrow{\text{grad}}(E_p) \tag{9.3.604}$$

In the case of gravity:

$$\vec{F}=m\vec{g}=-\overrightarrow{\text{grad}}(E_p) \tag{9.3.605}$$

which is also written with the nabla operator (see section Vector Calculus page 1869):

$$\boxed{\vec{F}=-\overrightarrow{\text{grad}}(E_p)=-\vec{\nabla}(E_p)} \tag{9.3.606}$$

That is common to write also:

$$\vec{F}=-\vec{\nabla}U \tag{9.3.607}$$

That is to say in the one dimensional case:

$$\boxed{\vec{F}=-\frac{\partial U}{\partial x}} \tag{9.3.608}$$

So what we have seen so far about the potential energy bring us to what we name the "potential theory" and resumed by:

$$\begin{tikzcd}
& \boxed{\vec{F}=-\vec{\nabla}U} \arrow[dl] \arrow[dr, shift right] & \\
\boxed{\vec{\nabla}\times\vec{F}=\vec{0}} \arrow[rr, shift left] & & \boxed{\oint_\Gamma \vec{F}\circ \mathrm{d}\vec{r}=0} \arrow[ul, shift right] \arrow[ll, shift left]
\end{tikzcd}$$

Figure 9.73: **Potential theory summary**

9.3.8.4.1 Generalized Newton law

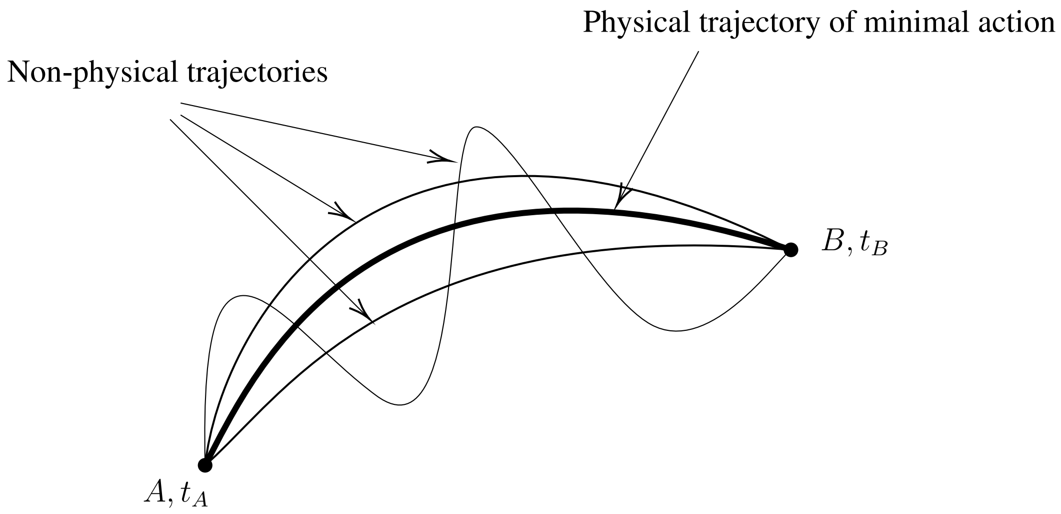
Now that we know explicitly how to express a kinetic and potential energy, let us come back to our principle of least action that we talked about in the section of Analytical Mechanics to proved that we can use it that latter to fall back on the generalized Newton's law demonstrated earlier in this section!

Let us take the case of an object launched into the air and let us choose two points of its motion path in any two different times. An infinite quantity of curves exist between these two points, but the Nature choose only one. So what distinguishes this curve - physical path - from all others? To answer this question we could quite rightly reply that this curve differs from others in that it is a solution of the differential equation of the path ... with appropriate initial conditions. But if we ignore the initial conditions or when the problem can not be reduced to a differential equation, by what method can we then distinguish the physical path of all possible paths?

The principle of last action in this context is expressed by a minimum speed for a minimum of motion path distance.

About speed, it is better in Mechanics to consider the quantity of linear momentum as the latter quantity is directly related to the inertial properties of the body. Pierre Louis Moreau de Maupertuis mathematically translated the principle of least action as follows for recall (see section Analytical Mechanics page 3152): If we consider the motion of a body between two points A in t_1 and B in t_2 by, for a given total energy E, the path selected by Nature is one for which the following quantity A_A^B is minimum:

$$\min A_A^B : \quad A_A^B = \int_{A,t_A}^{B,t_B} m\vec{v} \circ \mathrm{d}\vec{r} \tag{9.3.609}$$



Physical trajectory of minimal action
Non-physical trajectories
B, t_B
A, t_A

The physical path between two points A and B at times t_A and t_B is that for which the action is minimal!

Knowing that:

$$\mathrm{d}\vec{r} = \vec{v}\mathrm{d}t \tag{9.3.610}$$

then we get:

$$A_A^B = \int_{t_A}^{t_B} m\vec{v} \circ \vec{v}\mathrm{d}t = \int_{t_A}^{t_B} mv^2\mathrm{d}t = \int_{t_A}^{t_B} 2T(\vec{r},t)\mathrm{d}t \tag{9.3.611}$$

where T is as we the kinetic energy E_c of the body but as denoted in Analytical Mechanics...

We see that the action takes a surprisingly simple form and is expressed directly in terms of kinetic energy T. A few years later, from an intuition similar to that of Maupertuis, Leonhard Euler came to a very similar statement of the action but starting from the premise that the moving body tend to adopt a state where the potential energy is minimal. The Euler's action was expressed in terms of the potential energy rather than kinetic energy. Who of Maupertuis or Euler was right?

In fact, their personal definition Action were equivalent. We know that in a conservative field if we denote by U the potential energy then the total energy E_{tot} is equal to $T+U$ and the energy is a constant (in an isolated system). We derive immediately that $T=E_{\text{tot}}-U$ and therefore:

$$2T = T + E_{\text{tot}} - U \tag{9.3.612}$$

Hence:

$$A_A^B = \int_{t_A}^{t_B} (T(\vec{r},t) + E_{\text{tot}} - U(\vec{r},t)+)\mathrm{d}t \tag{9.3.613}$$

This relation is true regardless of the initial total energy E_{tot} of the path. We conclude that the value of the constant E_{tot} does not discriminate between different paths and can thus be removed from the formulation of the action. The action of Maupertuis can then be reduced to a new quantity denoted S (we fall back on the notations seen in the section of Analytical Mechanics):

$$S_A^B = \int_{t_A}^{t_B} (T(\vec{r},t) - U(\vec{r},t)+)\mathrm{d}t = \int_{t_A}^{t_B} L(\vec{r},t)\mathrm{d}t \tag{9.3.614}$$

This new formulation of the action was given by Joseph-Louis Lagrange in 11788 (holocene calendar). S is as we already know the "Lagrangian's action" (see section Analytical Mechanics page 3161) and the function:

$$L(\vec{r},t) = T(\vec{r},t) - U(\vec{r},t) \tag{9.3.615}$$

is named as we know the "Mechanics Lagrangrian". Thus formulated, the principle of least action became one of the most powerful tools of mechanics and above.

We have already seen how we express the principle of least action mathematically (see section Analytical Mechanics page 3152). In our case, the action is not a function of analytical variables but of trajectories!

Let us consider the simple case of a body of mass m that is moving on a single dimension (which we represent by the x-axis) of a point of abscissa x_1 at the moment t_1 to a point x_2 at a moment t_2. Let us suppose that the body is subject to a potential U that does not vary with the time that is to say $U=U(x)$. The action on this body on any path Γ going from (x_1,t_1) to (x_2,t_2) is then:

$$S(\Gamma)=\int\limits_{t_1}^{t_2}(T(x,t)-U(x)]\mathrm{d}t=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2-U(x)\right)\mathrm{d}t \qquad (9.3.616)$$

Given Γ_0 the physical path and S_0 the action on this path. Let us denote by $\bar{x}$ the values of the position x on the physical path. Let us consider now a path Γ very near of Γ_0 such that the positions along the path Γ have the values $x(t)=\bar{x}(t)+\varepsilon(t)$ that we will write, to facilitate the notations: $x=\bar{x}+\varepsilon$.

Remark

The Lagrangian action of a curve $\gamma\in\mathcal{C}(x,y,\tau)$ is often denoted (for a unit mass, i.e. $m=1$):

$$\mathcal{A}_L(\gamma)=\int\limits_a^b L(\gamma,\dot{\gamma})\mathrm{d}t=\int\limits_a^b\left(\frac{1}{2}\|\dot{\gamma}\|^2+U(\gamma)\right)\mathrm{d}t$$

Or when there is no potential:

$$\mathcal{A}_L(\gamma)=\int\limits_a^b L(\gamma,\dot{\gamma})\mathrm{d}t=\int\limits_a^b\frac{1}{2}\|\dot{\gamma}\|^2\mathrm{d}t$$

Let us now calculate the action for this path:

$$S(\Gamma)=\int\limits_{t_1}^{t_2}\left(\frac{1}{2}m\left(\frac{\mathrm{d}(\bar{x}+\varepsilon)}{\mathrm{d}t}\right)^2-U(\bar{x}+\varepsilon)\right)\mathrm{d}t \qquad (9.3.617)$$

As ε is infinitely small, it is possible to express the potential as a limited Taylor development (see section Sequences and Series page 1696):

$$U(\bar{x}+\varepsilon)\cong U(\bar{x})+\frac{1}{1!}\frac{\mathrm{d}U}{\mathrm{d}x}\varepsilon=U(\bar{x})+\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x} \qquad (9.3.618)$$

And for the first term we simply develop the square identity:

$$\left(\frac{\mathrm{d}(\bar{x}+\varepsilon)}{\mathrm{d}t}\right)^2=\left(\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\right)^2+2\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}+\left(\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}\right)^2 \qquad (9.3.619)$$

As we consider only the variations of the first order (very small one), the last term above can be neglected, which gives for the action on the path Γ:

$$S(\Gamma)=\int\limits_{t_1}^{t_2}\left[\frac{1}{2}m\left(\left(\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\right)^2+2\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}\right)-U(\bar{x})-\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x}\right]\mathrm{d}t \qquad (9.3.620)$$

Let us now put the variation δ of the action between the physical path Γ_0 and Γ is zero as it seems to be observed in Classical Mechanics labs:

$$\delta S=S(\Gamma)-S(\Gamma_0)=0 \qquad (9.3.621)$$

Therefore:

$$\begin{aligned}\delta S &= S(\Gamma)-S(\Gamma_0)\\ &=\int_{t_1}^{t_2}\left[\frac{1}{2}m\left(\left(\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\right)^2+2\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}\right)-U(\bar{x})-\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x}\right]\mathrm{d}t-\int_{t_1}^{t_2}\left[\frac{1}{2}m\left(\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\right)^2-U(\bar{x})\right]\mathrm{d}t\\ &=\int_{t_1}^{t_2}\left(m\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}-\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x}\right)\mathrm{d}t\end{aligned} \tag{9.3.622}$$

The first term in the last integral above can be integrated by parts as follows (see section Differential and Integral Calculus page 1532):

$$\int_{t_1}^{t_2} m\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}\mathrm{d}t=m\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\varepsilon(t)\Big|_{t_1}^{t_2}-\int_{t_1}^{t_2} m\varepsilon\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}\mathrm{d}t \tag{9.3.623}$$

But, all paths starting from x_1 at time t_1 and arriving at x_2 at time t_2. This implies that in t_1 and t_2 the variation of ε is zero, what we write:

$$\varepsilon(x_1,t_1)=\varepsilon(x_2,t_2)=0 \tag{9.3.624}$$

so the first term of integration by parts is zero such that:

$$\int_{t_1}^{t_2} m\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}\mathrm{d}t=-\int_{t_1}^{t_2} m\varepsilon\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}\mathrm{d}t \tag{9.3.625}$$

So finally:

$$\delta S=\int_{t_1}^{t_2}\left(m\frac{\mathrm{d}\bar{x}}{\mathrm{d}t}\frac{\mathrm{d}\varepsilon}{\mathrm{d}t}-\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x}\right)\mathrm{d}t=\int_{t_1}^{t_2}\left(-m\varepsilon\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}-\varepsilon\frac{\mathrm{d}U}{\mathrm{d}x}\right)\mathrm{d}t=-\int_{t_1}^{t_2}\left(m\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}+\frac{\mathrm{d}U}{\mathrm{d}x}\right)\varepsilon\mathrm{d}t \tag{9.3.626}$$

As this integral must be zero for all of the paths very close of the physical path Γ_0, regardless of the value of ε, the for such a condition to be fulfilled it seems necessary that the term in front of ε is zero, that is to say:

$$m\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}+\frac{\mathrm{d}U}{\mathrm{d}x}=0 \tag{9.3.627}$$

But we know in fact that the first term is nothing but $m\cdot a$ where a is the (average) acceleration of the body, and the second - the opposite of the potential gradient - is the amount of the gravitational force in a given point. This can the be rewritten as (but when the force is zero):

$$\boxed{F=m\frac{\mathrm{d}^2\bar{x}}{\mathrm{d}t^2}+\frac{\mathrm{d}U}{\mathrm{d}x}=m\bar{a}+\frac{\mathrm{d}}{\mathrm{d}x}U} \tag{9.3.628}$$

So we fall back on the generalized Newton's second law already developed at the beginning of the section!!!!

The principle of least action thus implicitly contains Newtonian Mechanics. Thus, it is possible to reconstruct the entire Newtonian Mechanics with the only the principle of least action and some assumptions!!!

This scaffolding of calculations may seem complicated to achieve only t a result that we already knew but the whole point of the principle of least action is that it allows to draw the basic laws from the only knowledge of the Lagrangian of a system (see section Analytical Mechanics page 3155).

The most recent theories such as Quantum Field Theory, Gauge Theories or Superstring Theory all have to start the expression of the action of the system (see corresponding sections in this textbook). Physicists then extract fundamental laws governing the behaviour of elementary particles.

9.3.8.5 Conservation of Linear Momentum

A moving object, during an interaction (collision) with another moving object point may transmit all or part of its motion (kinetic energy and / or potential). This is the case during an impact, for example (in fact the detailed calculation an impact is extremely difficult to do without many simplifications). And the exchanged quantity is the linear momentum $\vec{p}$. It is equal by definition (as we have seen it earlier above):

$$\vec{p}=m\vec{v} \tag{9.3.629}$$

Obviously, we have:

$$\boxed{m\vec{v}_2-m\vec{v}_1=\int_{t_1}^{t_2}\vec{F}\mathrm{d}t} \tag{9.3.630}$$

The quantity:

$$\int\limits_{t_1}^{t_2}\vec{F}\mathrm{d}t \tag{9.3.631}$$

is sometimes named "impulse", and the above relation sometimes is named "momentum theorem".

This theorem is stated as follows: The impulse supplied by a force between the moments t_1 and t_2 is equal to the variation of the amount of linear momentum during this time interval.

But let us come back to our conservation of linear momentum (and thus energy ... and vice versa). The interest of the quantity of linear momentum is due to the fact that it is preserved in interactions in Classical Mechanics (at least in first approximation...). Indeed, given two moving objects in collision, under the equality of action and reaction (3rd Newton's law) we have:

$$\vec{F}_{2,1}=-\vec{F}_{1,2} \tag{9.3.632}$$

and using the theorem of linear moment we can write:

$$\frac{\mathrm{d}\vec{p}_1}{\mathrm{d}t}=\vec{F}_{2,1} \quad \text{and} \quad \frac{\mathrm{d}\vec{p}_2}{\mathrm{d}t}=\vec{F}_{1,2} \tag{9.3.633}$$

By adding member to member these two equations, we deduce:

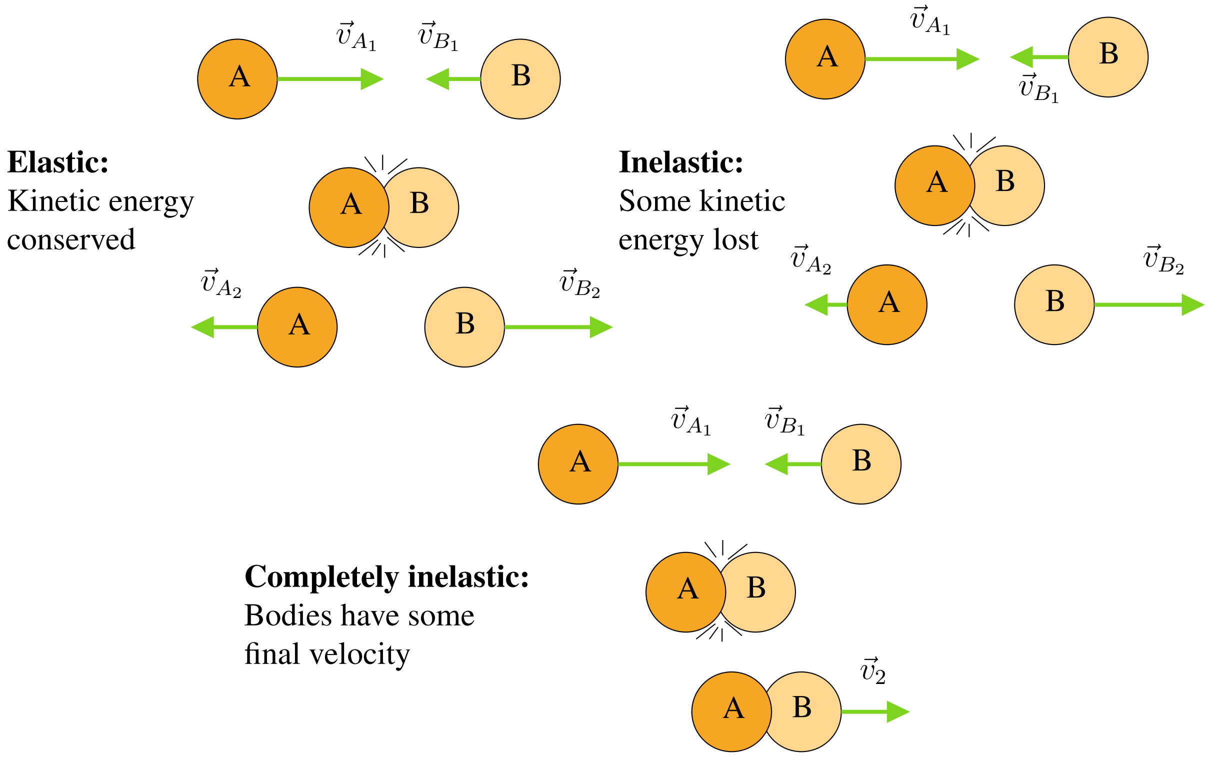
$$\frac{\mathrm{d}}{\mathrm{d}t}(\vec{p}_1+\vec{p}_2)=\vec{F}_{2,1}+\vec{F}_{1,2}=\vec{0} \tag{9.3.634}$$

as $\vec{F}_{2,1}=-\vec{F}_{1,2}$ and therefore in a "perfect" collision:

$$\boxed{\vec{p}_1+\vec{p}_2=c^{te}} \tag{9.3.635}$$

The total linear momentum is constant, it is therefore conserved!

Definition (#9.3.446): An "elastic collision" is an encounter between two bodies in which the total kinetic energy of the two bodies after the encounter is equal to their total kinetic energy before the encounter (the objects in question "bounce perfectly" like an ideal elastic). Elastic collisions occur only if there is no net conversion of kinetic energy into other forms (such as heat or noise):



$\vec{v}_{A_1}$
$\vec{v}_{B_1}$
A
B
Elastic:
Kinetic energy
conserved
$\vec{v}_{A_2}$
$\vec{v}_{B_2}$
Inelastic:
Some kinetic
energy lost
Completely inelastic:
Bodies have some
final velocity
$\vec{v}_2$

Definition (#9.3.447): An "inelastic collision" is one where some of the of the total kinetic energy is transformed into other forms of energy, such as sound and heat. Any collision in which the shapes of the objects are permanently altered, some kinetic energy is always lost to this deformation, and the collision is not elastic. It is common to refer to a "completely inelastic" collision whenever the two objects remain stuck together, but this does not mean that all the kinetic energy is lost; if the objects are still moving, they will still have some kinetic energy.

Remark

We will study in details an example of two body (non-relativistic) aligned elastic collision during our study of Newton Pendulum further below as a special case of the example above.

9.3.8.5.1 Elastic Collision in 1-dimensions

Given two objects, m_1 and m_2, with initial velocities of v_{1i} and v_{2i}, respectively, how fast will they be going after they undergo a completely elastic collision? We can derive some expressions for v_{1f} and v_{2f} by using the conservation of kinetic energy and the conservation of momentum, and a lot of high-school algebra.

Begin by making the following conservation statements:

- Conservation of Kinetic Energy:

$$\frac{1}{2}m_1v_{1i}^2+\frac{1}{2}m_2v_{2i}^2=\frac{1}{2}m_1v_{1f}^2+\frac{1}{2}m_2v_{2f}^2 \tag{9.3.636}$$

- Conservation of Momentum[16]:

$$m_1v_{1i}+m_2v_{2i}=m_1v_{1f}+m_2v_{2f} \tag{9.3.637}$$

To solve for v_{1f} and v_{2f} (which is really two equations in two unknowns), we need some algebra tricks to simplify the substitutions. Take both equations and group them according to the masses: put all the m_1 on one side of the equation and all the m_2 on the other. We'll also cancel out all the $1/2$ at this point.

Conservation of Kinetic Energy becomes:

$$m_1v_{1i}^2-m_1v_{1f}^2=m_2v_{2f}^2-m_2v_{2i}^2 \tag{9.3.638}$$

which can be simplified as:

$$m_1(v_{1i}^2-v_{1f}^2)=m_2(v_{2f}^2-v_{2i}^2) \tag{9.3.639}$$

Conservation of momentum becomes:

$$m_1v_{1i}-m_1v_{1f}=m_2v_{2f}-m_2v_{2i} \tag{9.3.640}$$

which can be simplified as:

$$m_1(v_{1i}-v_{1f})=m_2(v_{2f}-v_{2i}) \tag{9.3.641}$$

Now comes the algebra fun. We divide:

$$m_1(v_{1i}^2-v_{1f}^2)=m_2(v_{2f}^2-v_{2i}^2) \tag{9.3.642}$$

by:

$$m_1(v_{1i}-v_{1f})=m_2(v_{2f}-v_{2i}) \tag{9.3.643}$$

Hence:

$$\frac{m_1(v_{1i}^2-v_{1f}^2)}{m_1(v_{1i}-v_{1f})}=\frac{m_2(v_{2f}^2-v_{2i}^2)}{m_2(v_{2f}-v_{2i})} \tag{9.3.644}$$

---

[16] Conservation of momentum explains for example why when you jump inside a moving vehicle, you still move at the same speed of the vehicle. Or when you jump on Earth you still move with the rotating Earth...

After all the cancellations, we are left with:

$$v_{1i}+v_{1f}=v_{2f}+v_{2i} \tag{9.3.645}$$

Solving for v_{1f} we get:

$$v_{1f}=v_{2f}+v_{2i}-v_{1i} \tag{9.3.646}$$

Now we take the previous equation and substitute back into one of our original equations to solve for v_2f. Since the momentum equation is easier, lets use that.

Conservation of momentum becomes:

$$m_1v_{1i}+m_2v_{2i}=m_1(v_{2f}+v_{2i}-v_{1i})+m_2v_{2f} \tag{9.3.647}$$

Now we do some algebra...:

$$\begin{aligned}
&m_2v_{2f}+m_1v_{2f}=m_1v_{1i}+m_2v_{2i}-m_1(v_{2i}-v_{1i})\\
&(m_2+m_1)v_{2f}=m_1v_{1i}+m_1v_{1i}+m_2v_{2i}-m_1v_{2i}\\
&v_{2f}=\frac{(m_1+m_1)}{(m_2+m_1)}v_{1i}+\frac{(m_2-m_1)}{(m_2+m_1)}v_{2i}
\end{aligned} \tag{9.3.648}$$

Until we get:

$$\boxed{v_{2f}=\frac{2m_1}{m_2+m_1}v_{1i}+\frac{m_2-m_1}{m_2+m_1}v_{2i}} \tag{9.3.649}$$

Now we substitute this result back into equation:

$$v_{1f}=v_{2f}+v_{2i}-v_{1i} \tag{9.3.650}$$

do some algebra to solve for v_{1f}:

$$v_{1f}=\left(v_{2f}=\frac{2m_1}{m_2+m_1}v_{1i}+\frac{m_2-m_1}{m_2+m_1}v_{2i}\right)+v_{2i}-v_{1i} \tag{9.3.651}$$

Now do some algebra again...:

$$\begin{aligned}
&v_{1f}=\left(\frac{2m_1}{m_2+m_1}-1\right)v_{1i}+\left(\frac{m_2-m_1}{m_2+m_1}+1\right)v_{2i}\\
&v_{1f}=\left(\frac{2m_1-(m_2+m_1)}{m_2+m_2}\right)v_{1i}+\left(\frac{(m_2-m_1)+(m_2+m_1)}{m_2+m_1}\right)v_{2i}
\end{aligned} \tag{9.3.652}$$

Until we get:

$$\boxed{v_{1f}=\frac{m_1-m_2}{m_2+m_1}v_{1i}+\frac{2m_2}{m_2+m_1}v_{2i}} \tag{9.3.653}$$

The reader can notice that in the special well known case where $v_{2i}=0$ and $m_2=m_1$ the both boxed relations above give us:

$$v_{2f}=v_{1i} \qquad v_{1f}=0 \tag{9.3.654}$$

Notice that in the case where $m_1 \gg m_2$, we have:

$$\begin{aligned} v_{1f} &= \left(\frac{m_1-m_2}{m_1+m_2}\right)v_{1i}+\left(\frac{2m_2}{m_1+m_2}\right)v_{2i}\cong v_{1i} \\ v_{2f} &= \left(\frac{2m_1}{m_1+m_2}\right)v_{1i}+\left(\frac{m_2-m_1}{m_1+m_2}\right)v_{2i}\cong 2v_{1i}+v_{2i} \end{aligned} \tag{9.3.655}$$

This is perfectly represented by the illustration below:

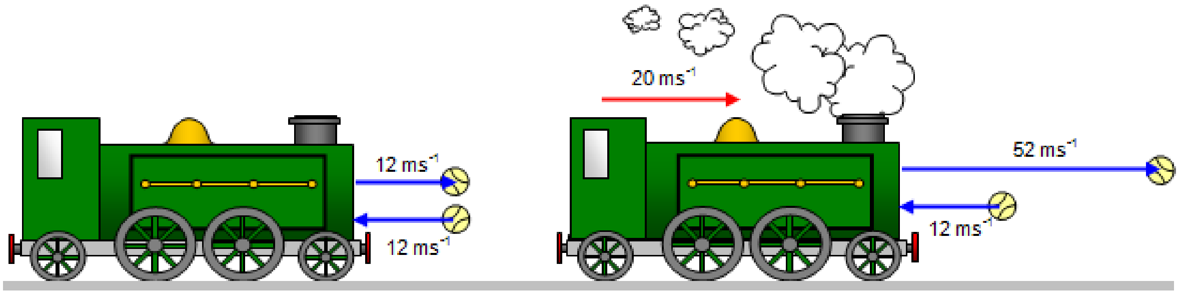


Figure 9.74: Elastic collision with $m_1 \gg m_2$ (source: schoolphysics.co.uk, author: Keith Gibbs)

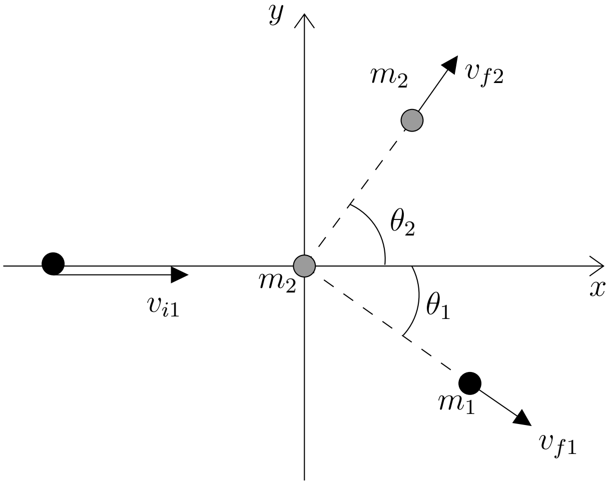
The last relation if famously known in aerospace engineering in the framework of gravity assist and traditionally denoted:

$$v_f = 2U + v_i \tag{9.3.656}$$

9.3.8.5.2 Elastic Collision in 2-dimensions

Suppose that an object of mass m_1, moving with initial speed v_{i1}, strikes a second object, of mass m_2, which is initially at rest. Suppose, further, that the collision is not head-on, so that after the collision the first object moves off at an angle θ_1 to its initial direction of motion, whereas the second object moves off at an angle θ_2 to this direction:



Let the final speeds of the two objects be v_{f1} and v_{f2}, respectively.

We are again considering a system in which there is zero net external force (the forces associated with the collision are internal in nature). It follows that the total momentum of the system is a conserved quantity. However, unlike before, we must now treat the total momentum as a vector quantity, since we are no longer dealing with 1-dimensional motion. Note that if the collision takes place wholly within the x-y plane, as indicated in the figure above, then it is sufficient to equate the x- and y-components of the total momentum before and after the collision.

Consider the x-component of the system's total momentum. Before the collision, the total x-momentum is simply $m_1 v_{i1}$, since the second object is initially stationary, and the first object is initially moving along the x-axis with speed v_{i1}. After the collision, the x-momentum of the first object is $m_1 v_{f1}\cos(\theta_1)$: i.e., m_1 times the x-component of the first object's final velocity. Likewise, the final x-momentum of the second object is $m_2 v_{f2}\cos(\theta_2)$. Hence, momentum conservation in the x-direction yields:

$$m_1 v_{i1} = m_1 v_{f1}\cos(\theta_1) + m_2 v_{f2}\cos(\theta_2) \tag{9.3.657}$$

Consider the y-component of the system's total momentum. Before the collision, the total y-momentum is zero, since there is initially no motion along the y-axis. After the collision, the y-momentum of the first object is $-m_1 v_{f1}\sin(\theta_1)$: i.e., m_1 times the y-component of the first object's final velocity. Likewise, the final y-momentum of the second object is $m_2 v_{f2}\sin(\theta_2)$. Hence, momentum conservation in the y-direction yields:

$$m_1 v_{f1}\sin(\theta_1) = m_2 v_{f2}\sin(\theta_2) \tag{9.3.658}$$

For the special case of an elastic collision, we can equate the total kinetic energies of the two objects before and after the collision. Hence, we obtain

$$\frac{1}{2}m_1 v_{i1}^2 = \frac{1}{2}m_1 v_{f1}^2 + \frac{1}{2}m_2 v_{f2}^2 \tag{9.3.659}$$

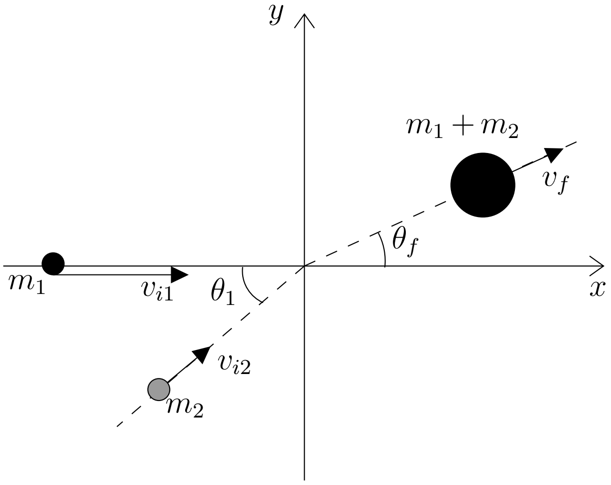
Given the initial conditions (i.e., m_1, m_2, and v_{i1}), we have a system of 3 equations:

$$\begin{aligned} &m_1 v_{i1} = m_1 v_{f1}\cos(\theta_1) + m_2 v_{f2}\cos(\theta_2) \\ &m_1 v_{f1}\sin(\theta_1) = m_2 v_{f2}\sin(\theta_2) \\ &\frac{1}{2}m_1 v_{i1}^2 = \frac{1}{2}m_1 v_{f1}^2 + \frac{1}{2}m_2 v_{f2}^2 \end{aligned} \tag{9.3.660}$$

and 4 unknowns (i.e., θ_1, θ_2, v_{f1}, and v_{f2}). Clearly, we cannot uniquely solve such a system without being given additional information: e.g., the direction of motion or speed of one of the objects after the collision.

9.3.8.5.3 Inelastic Collision in 2-dimensions

The figure below shows a 2-dimensional totally inelastic collision.



In this case, the first object, mass m_1, initially moves along the x-axis with speed v_{i1}. On the other hand, the second object, mass m_2, initially moves at an angle θ_i to the x-axis with speed v_{i2}. After the collision, the two objects stick together and move off at an angle θ_f to the x-axis with speed v_f. Momentum conservation along the x-axis yields

$$m_1v_{i1}+m_2v_{i2}\cos(\theta_i)=(m_1+m_2)v_f\cos(\theta_f) \tag{9.3.661}$$

Likewise, momentum conservation along the y-axis gives

$$m_2v_{i2}\sin(\theta_i)=(m_1+m_2)v_f\sin(\theta_f) \tag{9.3.662}$$

Given the initial conditions (i.e., m_1, m_2, v_{i1}, v_{i2}, and θ_i), we have a system of two equations and two unknowns (i.e., v_f and θ_f). Clearly, we should be able to find a unique solution for such a system.

Remark

The "Newton's empirical law of restitution" (that cannot be proven mathematically as far as we know) defined by:

$$\varepsilon=\frac{v_{f2}-v_{f1}}{v_{i1}-v_{i2}} \tag{9.3.663}$$

is the ratio of the relative speed after the collision to the relative speed before the collision. If $\varepsilon=1$ the collision is perfectly elastic (no loss of kinetic energy), if $\varepsilon=0$ the bodies stick together at rest, if $0<\varepsilon<1$ it is partially inelastic (some loss of kinetic energy).

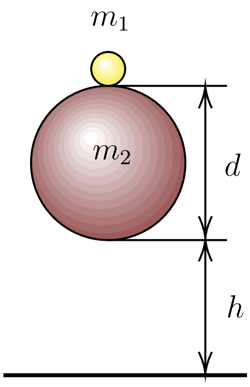
9.3.8.5.4 Rebound (stacked ball drop)

Often simple experiments can be conducted to reveal explanations to seemingly complex phenomena that are counter-intuitive for most people. Supernovas and gravitational assist orbits can be better understood by investigating conservation of energy and momentum in a stacked ball drop. A stacked ball drop is when two or more balls are stacked vertically and dropped, and the top ball (ball 1) has a rebound height greater than the initial drop height. In a scenario with two balls being dropped, the bottom ball's (ball 2) collision with the floor changes its velocity from the downwards direction to upwards. Ball 1 is travelling downwards when it collides with ball 2 which is travelling upwards. In this collision, ball 2 transfers energy to ball 1, changing the direction and magnitude of the velocity of ball 1. Using equations of conservation of energy and momentum, we can calculate the rebound height.

This phenomenon relates to a supernova because the star has a dense core that transfers a shock wave of energy outward. The transfer of energy from the dense core outward to the less dense layers causes the less dense layers to accelerate, resulting in a large velocity. Collisions are typically thought of as two or more objects making physical contact; however, the same principle can be applied to a spacecraft utilizing a gravity assist maneuver. When a spacecraft enters a planet's gravitational field some of the planet's orbital energy can be transferred to the spacecraft, increasing the velocity of said spacecraft. The sum of kinetic energy of the planet and spacecraft is preserved, however, so the interaction can be considered an elastic collision.

To understand how a larger rebound height occurs, we will examine the scenario as an elastic collision (the text below is almost a copy paste of the one written by Tan Chien Hao)!

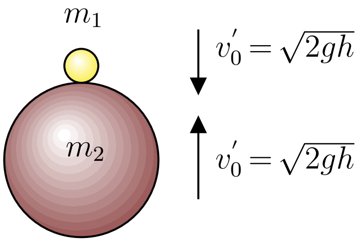
A tennis ball with a small mass of m_2 sits on top of a basketball with a large mass m_1, as shown in the figure below. The bottom of the basketball is at the height h above the ground, and the bottom of the tennis ball is at a height $h+d$ above the ground, where d is the diameter of the ball:



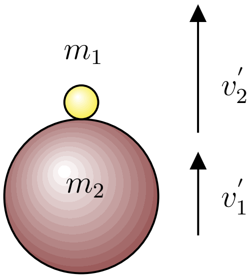
The balls are then dropped from rest. We want to find the height that the tennis ball bounces to in terms of h and d, using the approximation that $m_1 \gg m_2$. We assume that the collisions are all elastic, and that the two balls are initially separated by a very small separation and also that the balls bounce instantaneously.

We know that both balls will fall with acceleration g. And right before they hit the ground, both balls have velocity $v_0 = \sqrt{2gh}$. There will be two collisions that occur. The first collision is between the basketball (ball with mass m_1) and the ground. The second collision is between the basketball (ball with mass m_1) and the tennis ball (ball with mass m_2).

The first collision just flips the direction of the velocity of the basketball:



Let's take a look at the second collision:



So we have two unknowns. That means we need two equations. A guess would be to use the conversion of momentum and the conservation of energy.

So let us put the conservation of momentum (the minus sign on $m_2 v_0$ is non-obvious!):

$$m_1 v_0 - m_2 v_0 = m_1 v_1' + m_2 v_2' \quad (9.3.664)$$

and rearrange:

$$m_1 (v_0 - v_1') = m_2 (v_0 + v_2') \quad (9.3.665)$$

And let us put the conservation of energy:

$$\frac{1}{2} m_1 v_0^2 + \frac{1}{2} m_2 v_0^2 = \frac{1}{2} m_1 v_1'^2 + \frac{1}{2} m_2 v_2'^2 \quad (9.3.666)$$

We factorise the latter:

$$m_1 (v_0 - v_1')^2 = -m_2 (v_0 - v_2')^2 \quad (9.3.667)$$

Or that we can rewrite obviously as:

$$m_1 (v_0 - v_1')(v_0 + v_1') = -m_2 (v_0 - v_2')(v_0 + v_2') \quad (9.3.668)$$

If we divide the latter by the relation:

$$m_1 (v_0 - v_1') = m_2 (v_0 + v_2') \quad (9.3.669)$$

that we got earlier, we have therefore:

$$v_0+v'_1=v'_2-v_0 \quad (9.3.670)$$

Simplifying we get:

$$v'_1=v'_2-2v_0 \quad (9.3.671)$$

That we can inject back into the equation of conservation of momentum, given for reminder by:

$$m_1v_0-m_2v_0=m_1v'_1+m_2v'_2 \quad (9.3.672)$$

to get:

$$\begin{aligned}(m_1-m_2)\,v_0&=m_1\,(v'_2-2v_0)+m_2v'_2\\&=(m_1+m_2)\,v'_2-2m_1v_0\end{aligned} \quad (9.3.673)$$

Rearranging:

$$\frac{3m_1-m_2}{m_1+m_2}v_0=v'_2 \quad (9.3.674)$$

In the limit $m_1 \gg m_2$:

$$3v_0=v'_2 \quad (9.3.675)$$

Or written more traditionally:

$$\boxed{v_f=3v_0} \quad (9.3.676)$$

So the final speed of the small ball is three times its falling speed. And this is the important result that we wanted and that can be illustrated as below:

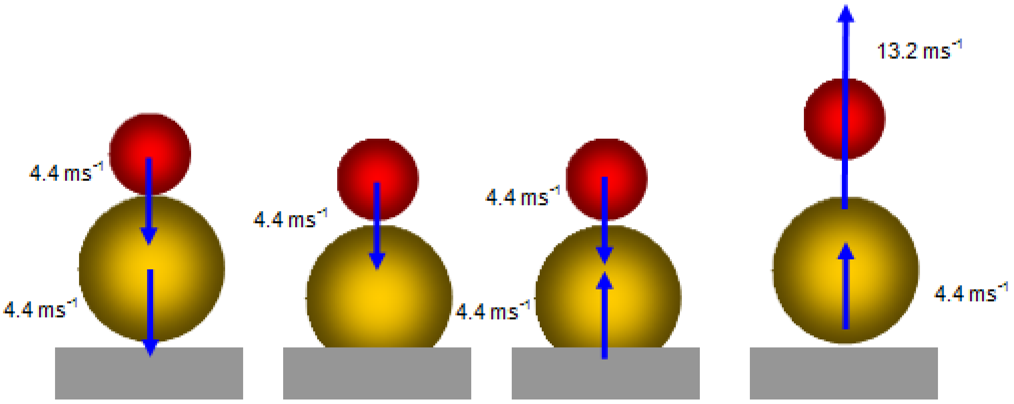


Figure 9.75: **Two balls rebound (source: schoolsphysics.co.ok, author: Keith Gibbs)**

We can also get the height of second tennis ball:

$$h_2=d+\frac{v_2'^2}{2g}=d+9\frac{v_0^2}{2g}=d+9h \quad (9.3.677)$$

✍**Example:**

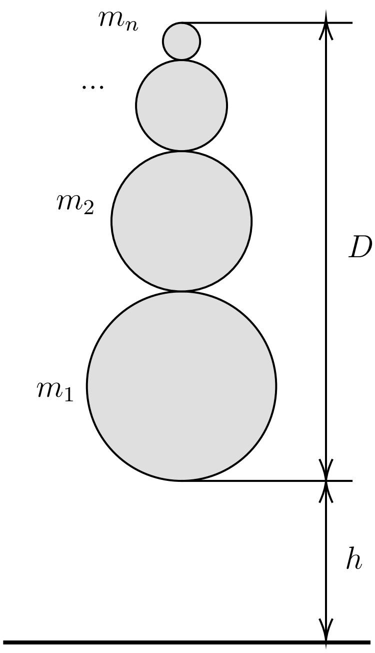
Imagine now that you have a set of 12 balls, each one being much smaller than the last with ball 1 being the biggest (heaviest). If you carefully stacked the balls one on top of the other and dropped the pile vertically onto the hard ground some amazing things happen. Each ball acts on the one above it and the result is an extension of the effect with only two balls.

The results are shown in the diagram (not to scale) and in the table. Ball 6 will reach just over $3,900$ [m] – nearly half the height of Mount Everest and its speed of rebound will be almost $280\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$. The ball 12 would reach a speed of over $280\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$, greater than the escape velocity of the Earth and travel off into space!

	Recoil speed	**Height risen**
Ball 1	$4.4\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$1\,[\mathrm{m}]$
Ball 2	$13.2\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$8.9\,[\mathrm{m}]$
Ball 3	$31\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$48.4\,[\mathrm{m}]$
Ball 4	$66\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$222.2\,[\mathrm{m}]$
Ball 5	$136\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$949.2\,[\mathrm{m}]$
Ball 6	$277\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$3.9\,[\mathrm{km}]$
Ball 7	$559\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$	$15.9\,[\mathrm{km}]$
Ball 8	$1.1\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$	$64.2\,[\mathrm{km}]$
Ball 9	$2.2\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$	$258\,[\mathrm{km}]$
Ball 10	$4.5\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$	$1,033\,[\mathrm{km}]$
Ball 11	$9\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$	$4,140\,[\mathrm{km}]$
Ball 12	$18\,[\mathrm{km}\cdot\mathrm{s}^{-1}]$	orbit

Remember that all this assumes no loss of energy on impact, each successive ball must be much less massive than the one below it and air resistance must be ignored.

As supernovas are made of multiple layers, let us generalize the technique that we have just seen to n balls as illustrated below:



So we start as before with:

$$\begin{aligned}m_n v_n - m_{n+1} v_{n+1} &= m_n v'_n + m_{n+1} v'_{n+1}\\ m_n\left(v_n - v'_n\right) &= m_{n+1}\left(v_{n+1}+v'_{n+1}\right)\\ \frac{1}{2}m_n v_n^2 + \frac{1}{2}m_{n+1}v_{n+1}^2 &= \frac{1}{2}m_n v_n'^2 + \frac{1}{2}m_{n+1}v_{n+1}'^2\\ \Rightarrow m_n\left(v_n - v'_n\right)\left(v_n + v'_n\right) &= m_{n+1}\left(v'_{n+1}-v_{n+1}\right)\left(v'_{n+1}+v_{n+1}\right)\end{aligned} \quad (9.3.678)$$

Dividing the fourth line by the the second one, we get:

$$v_n + v'_n = v'_{n+1} - v_{n+1} \quad (9.3.679)$$

Rearranging, this gives:

$$v'_n = v'_{n+1} - v_{n+1} - v_n \quad (9.3.680)$$

Let us substitute into:

$$m_n v_n - m_{n+1} v_{n+1} = m_n v'_n + m_{n+1} v'_{n+1} \quad (9.3.681)$$

This lead us to:

$$\begin{aligned}m_n v_n - m_{n+1} v_{n+1} &= \left(m_n + m_{n+1}\right) v'_{n+1} - m_n\left(v_{n+1}+v_n\right)\\ m_n\left(2v_n + v_{n+1}\right) - m_{n+1}v_{n+1} &= \left(m_n + m_{n+1}\right) v'_{n+1}\\ \frac{m_n\left(2v_n + v_{n+1}\right) - m_{n+1}v_{n+1}}{m_n + m_{n+1}} &= v'_{n+1}\end{aligned} \quad (9.3.682)$$

In the limit $m_n \gg m_{n+1}$, the latter simplifies to:

$$2v_n + v_{n+1} = v'_{n+1} \quad (9.3.683)$$

This leads to a recurrence relation v_n for speed of ball n after the collision:

$$v_{n+1}=2v_n+\sqrt{2gh} \tag{9.3.684}$$

Hence:

$$\begin{aligned}v_1&=\sqrt{2gh}\\v_2&=3\sqrt{2gh}\\v_3&=7\sqrt{2gh}\\v_4&=15\sqrt{2gh}\end{aligned} \tag{9.3.685}$$

We can prove that $x_n=(2^n-1)\sqrt{2gh}$ by mathematical induction.

And we have for the height of the n-th ball:

$$h_n=D+\frac{v_n^2}{2g}=D+(2^n-1)^2 h \tag{9.3.686}$$

9.3.8.6 Power

Definition (#9.3.448): The "power" is the instantaneous rate of change of work (energy in any form). So we have the "instantaneous power" that is given by:

$$\boxed{P=\frac{\mathrm{d}W}{\mathrm{d}t}} \tag{9.3.687}$$

The unit of power is the "Watt" (J$\cdot$s^{-1}) and is denoted [W] but in technique, some still use the "horsepower" [ch] defined as being equal to 736 [W] (as an average horse could at that time lift 75 kilograms or 1 meter in 1 second under the Earth's gravity).

Remark

In the electric power industry, the megawatt electrical [MWe] unit refers by convention to the electric power produced by a generator, while megawatt thermal or thermal megawatt [MWt] refers to thermal power produced by the plant. For example, the Embalse nuclear power plant in Argentina uses a fission reactor to generate $2,109$ [MWt] (i.e. heat), which generates steam to drive a turbine, which generates 648 [MWe] (i.e. electricity). Other SI prefixes are sometimes used, for example gigawatt electrical [GWe]. The International Bureau of Weights and Measures, which maintains the SI-standard, states that further information about a quantity should not be attached to the unit symbol but instead to the quantity symbol (i.e., $P_{\text{th}}=270$ [W] rather than $P=270$ [Wth]) and so these units are non-SI!

When describing alternating current (AC) electricity, another distinction is made between the watt [W] and the volt-ampere [Va]. While these units are equivalent for simple resistive circuits, they differ when loads exhibit electrical reactance (voir section Électrocinétique pages 4263 and ??).

If the work is provided on a regular basis (constant), then we have the "average power":

$$P=\frac{P}{t} \tag{9.3.688}$$

that should be denoted $\bar{P}=P/t$ but depending on the context we don't need to strictly respect the notations!

With this definition, the reader might think that a vehicle travelling at a constant speed can therefore provides then a power equal to zero because its kinetic energy does not change. In reality it is not so, because the car has to constantly overcome the friction of the tires with the road (see further the study of tribology), the viscous friction with the air (see section Continuum Mechanics page 3465), and loss of energy due to vibration and friction of its own components like axles, ball bearings, springs, heat exchange entropy, etc. Thus, a vehicle must every second supply the energy he lost in these frictions and heat transfers. We then have the "power of force":

$$P=\frac{\mathrm{d}W}{\mathrm{d}t}=\frac{\mathrm{d}(F_t\cdot r)}{\mathrm{d}t}=F_T\frac{\mathrm{d}r}{\mathrm{d}t}=F_Tv \tag{9.3.689}$$

where we used the definition of work W (force over a distance) and where F_T is the sum of various forces.

However, because we have often have to account for acceleration when we apply a force, we usually write the equation in terms of average power and average speed:

$$\boxed{\bar{P}=F_T\bar{v}} \tag{9.3.690}$$

But this also apply to a rocket pushing a satellite in space vacuum far from any gravitational field!!!

Notice finally that we can also found in some books:

$$\bar{P}=ma\bar{v}=ma(\bar{a}\Delta t)\cong m\bar{v}^2\Delta t \tag{9.3.691}$$

Remarks

R1. Expressing the work W (energy) from the relation $W=Pt$ where as we have just seen the power is given in [kW] and the time in hours, it appears the unit of energy [kWh] (kilowatt hour), widely used in practice by power plant, transformators and various domestic devices.

R2. The $2,000$ [W] society is an environmental vision, first introduced in 11998 (holocene calendar) by the Swiss Federal Institute of Technology in Zürich (ETH Zurich), which pictures the average First World citizen reducing their overall average primary energy usage to no more than $2,000$ [W] (48 kilowatt-hours per day) by the year 12050 (holocene calendar) - and without lowering their standard of living.

Definition (#9.3.449): A "machine" is typically defined as a physical system that uses energy to perform specific tasks, often by mechanical, chemical, electrical or computational means. It generally consists of components that work together to carry out processes or manipulate materials, energy, or information. A machine can be as simple as a lever or pulley, or as complex as a computer or robotic system or even a human (biochemical machine).

9.3.8.6.1 Power of a turning machine

The elementary work $\mathrm{d}W$ done by the for $\vec{F}$ turning a solid (a cylinder in the case presented below) around its axis of symmetry of an angle θ is equal to:

$$\mathrm{d}W=F\mathrm{d}r=F\left(\frac{2\pi r}{2\pi}\mathrm{d}\theta\right)=Fr\mathrm{d}\theta \tag{9.3.692}$$

The instantaneous power is then:

$$P=\frac{\mathrm{d}W}{\mathrm{d}t}=Fr\frac{\mathrm{d}\theta}{\mathrm{d}t}=Fr\omega \tag{9.3.693}$$

Now, as we have defined it earlier the force momentum is:

$$Fr=||\overrightarrow{M}|| \tag{9.3.694}$$

The power of a couple (torque) is then given by:

$$\boxed{P=M\omega} \tag{9.3.695}$$

This is a very popular relation well known by people passionate by motor vehicles and mechanics. Indeed, knowing the engine torque (the moment of force) and the motor speed (that must be converted into the correct units), we easily get an approximation of the power developed by the engineer. If we divide the result by 736, the reader will get the horsepower.

✍**Example:**

A boat engine is operating at $9.0\cdot 10^4$ [W] with running at 300 revolutions per minute. The torque is then given by:

$$M=\frac{P}{\omega}=\frac{9.0\cdot 10^4}{\dfrac{300\cdot 2\pi}{60}}=2864.8\,[\mathrm{N}\cdot\mathrm{m}] \tag{9.3.696}$$

9.3.8.6.1.1 Power yield

Because of friction and unperfect materials, the power output by a machine known as "power output" is always less than the "input power" in an isolated system. We take account of this fact by using the "power yield" defined by:

$$\boxed{\eta=\frac{P_{\text{usable}}}{P_{\text{input}}}} \tag{9.3.697}$$

As the numerator and denominator are measured during the same amount of time we also have the equivalent in terms of energy:

$$\boxed{\eta=\frac{E_{\text{usable}}}{E_{\text{input}}}} \tag{9.3.698}$$

and named sometimes also "energy returned on energy invested (EROEI or ERoEI)" or "energy return on investment (EROI)".

When the EROEI of a resource is less than or equal to one, that energy source becomes a net "energy sink", and can no longer be used as a source of energy, but depending on the system might it might be useful for energy storage (for example a battery).

We will return in much more detail on the above relations in our study of Thermodynamics (see section of the same name page 3668).

Here is a non-exhaustive summary of what we have seen so far:

Name	**Translational**	**Rotational**
Position	x	θ
Velocity	$v=\frac{\mathrm{d}x}{\mathrm{d}t}$	$\omega=\frac{\mathrm{d}\theta}{\mathrm{d}t}$
Acceleration	$a=\frac{\mathrm{d}^2x}{\mathrm{d}t^2}$	$\alpha=\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}$
Position, constant a or α	$x=x_0+v_0t+\frac{1}{2}at^2$	$\theta=\theta_0+\omega_0t+\frac{1}{2}\alpha t^2$
Velocity, constant a or α	$v=v_0+at$	$\omega=\omega_0+\alpha t$
Inertia	m	$I=\int r^2\mathrm{d}m$
Force (torque)	$\vec{F}$	$\vec{M}=\vec{r}\times\vec{F}$
Momentum	$\vec{p}=m\vec{v}$	$\vec{b}=\vec{r}\times\vec{p}=I\vec{\omega}$
Newton's second law	$\sum\vec{F}=\frac{\mathrm{d}\vec{p}}{\mathrm{d}t}=m\vec{a}$	$\sum\vec{M}=\frac{\mathrm{d}\vec{b}}{\mathrm{d}t}=I\vec{\alpha}$
Work	$W=\vec{F}\circ\Delta\vec{x}$	$W=M\Delta\theta$
Kinetic energy	$E_c=\frac{1}{2}mv^2$	$E_c=\frac{1}{2}I\omega^2$
Power	$P=\vec{F}\circ\vec{v}$	$P=M\omega$
Momentum conservation	$\sum\vec{p}_\mathrm{i}=\sum\vec{p}_\mathrm{f}$	$\sum\vec{b}_\mathrm{i}=\sum\vec{b}_\mathrm{f}$
Equilibrium	$\sum\vec{F}=\vec{0}$	$\sum\vec{M}=\vec{0}$

Table 9.19: **Comparison of translational (or linear) and rotational (or angular) relations**

9.3.9 Relative Movements and Inertial Forces

Let us now see the developments that will allow us to bring a very important and useful element in fluid mechanics (see section Continuum Mechanics page 3770) and meteorology (see section Marine & Weather Engineering page 8239).

Let us consider a fixed reference system X, Y, Z and a mobile reference frame x, y, z. They are therefore in relative motion and we consider a possible rotation of the moving frame. So our purpose is to express the speed, the acceleration of a point P of the space thanks to the coordinates of the fixed reference frame (absolute coordinates) from those attached to the moving frame (relative coordinates) and to the translation movement of this same moving frame.

We define for our study:

- $\vec{r}=(x(t),y(t),z(t))$ position vector of P relatively to the mobile frame
- $\vec{r}_0=(x_0(t),y_0(t),z_0(t))$ position vector of P relatively to the fixed frame
- $\vec{\rho}=(\ldots)$ position vector of O relatively to the origin of the fixed frame
- $\vec{v}_a=(\ldots)$ absolute velocity of P relatively to the fixed frame (supposed as unknown)
- $\vec{a}_a=(\ldots)$ absolute acceleration of P relatively to the fixed frame (supposed as unknown)
- $\vec{v}_r=(\ldots)$ relative velocity of the point P relatively to the mobile frame (supposed as known)
- $\vec{a}_r=(\ldots)$ relative acceleration of the point P relatively to the mobile frame (supposed as known)
- $\vec{v}_e=(\ldots)$ translation velocity at the point O of the mobile frame relatively to the fixed frame (supposed as known)
- $\vec{a}_e=(\ldots)$ translation acceleration at the point O of the mobile frame relatively to the fixed frame (supposed as known)
- $\vec{\omega}=(\ldots)$ angular speed of the mobile frame

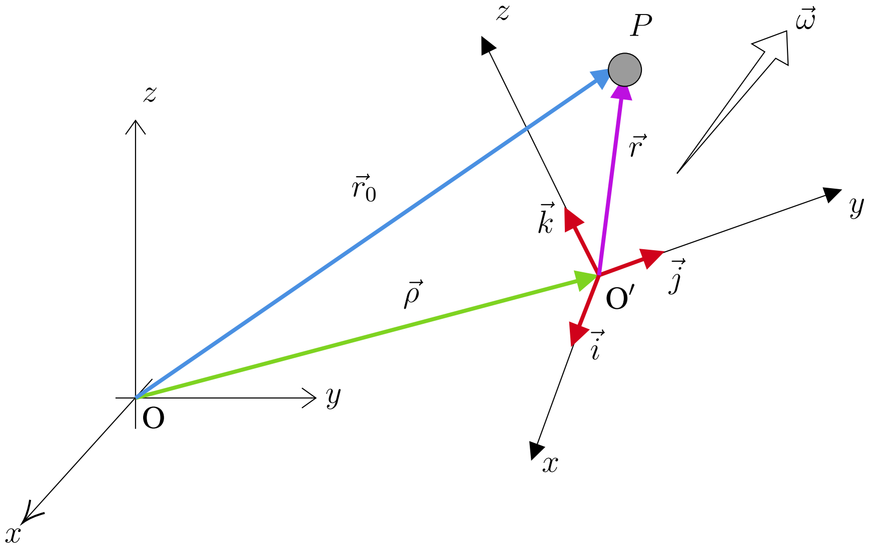


Figure 9.76: **Example of moving and rotating reference frame relatively to a fixed reference frame**

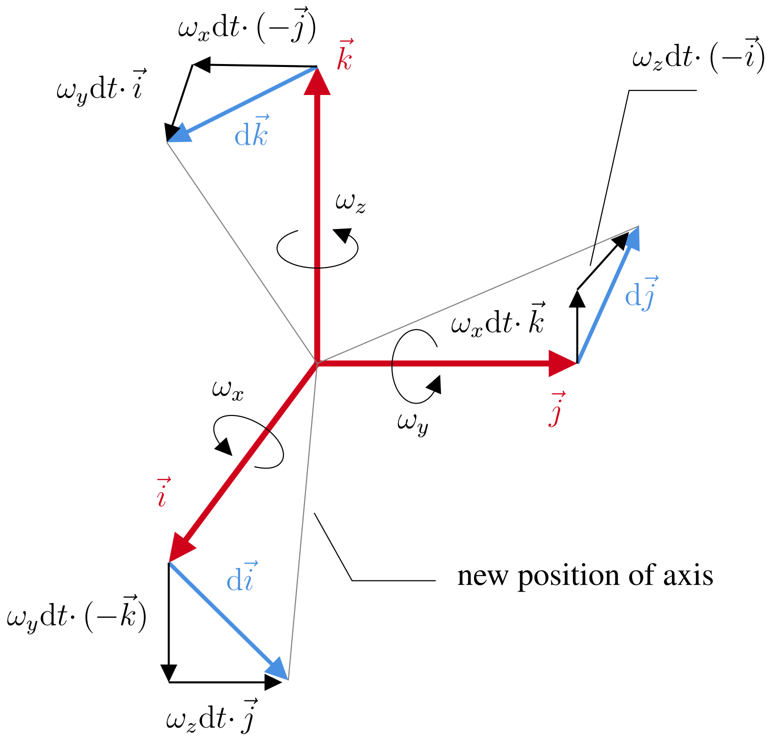
The position of the point P is therefore is given obviously by the "relation of composition of positions":

$$\vec{r}_0 = \vec{\rho} + \vec{r} \tag{9.3.699}$$

The absolute speed is calculated as follows:

$$\begin{aligned}\vec{v}_a = \frac{\mathrm{d}\vec{r}_0}{\mathrm{d}t} &= \frac{\mathrm{d}\vec{\rho}}{\mathrm{d}t} + \frac{\mathrm{d}\vec{r}}{\mathrm{d}t} = \frac{\mathrm{d}\vec{\rho}}{\mathrm{d}t} + \frac{\mathrm{d}}{\mathrm{d}t}(x\vec{i} + y\vec{j} + z\vec{k}) \\ &= \vec{v}_e + \left(\frac{\mathrm{d}x}{\mathrm{d}t}\vec{i} + \frac{\mathrm{d}y}{\mathrm{d}t}\vec{j} + \frac{\mathrm{d}z}{\mathrm{d}t}\vec{k}\right) + \left(x\frac{\mathrm{d}\vec{i}}{\mathrm{d}t} + y\frac{\mathrm{d}\vec{j}}{\mathrm{d}t} + z\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\right) \\ &= \vec{v}_e + \vec{v}_r + \left(x\frac{\mathrm{d}\vec{i}}{\mathrm{d}t} + y\frac{\mathrm{d}\vec{j}}{\mathrm{d}t} + z\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\right)\end{aligned} \tag{9.3.700}$$

The last term is the contribution due to the rotation of the moving frame. We have now to express the value of this contribution by considering rotations of angle $\mathrm{d}\theta_i = \omega_i \mathrm{d}t$ around each axis, successively:



$\omega_x\mathrm{d}t\cdot(-\vec{j})$
$\vec{k}$
$\omega_z\mathrm{d}t\cdot(-\vec{i})$
$\omega_y\mathrm{d}t\cdot\vec{i}$
$\mathrm{d}\vec{k}$
ω_z
$\mathrm{d}\vec{j}$
$\omega_x\mathrm{d}t\cdot\vec{k}$
ω_x
ω_y
$\vec{j}$
$\vec{i}$
$\mathrm{d}\vec{i}$
new position of axis
$\omega_y\mathrm{d}t\cdot(-\vec{k})$
$\omega_z\mathrm{d}t\cdot\vec{j}$

$$\mathrm{d}\vec{i}=(\vec{j}\omega_z-\vec{k}\omega_y)\mathrm{d}t \quad \mathrm{d}\vec{j}=(\vec{k}\omega_x-\vec{i}\omega_z)\mathrm{d}t \quad \mathrm{d}\vec{k}=(\vec{i}\omega_y-\vec{j}\omega_x)\mathrm{d}t$$

We obtain thus the elementary vectors $\mathrm{d}\vec{i},\mathrm{d}\vec{j},\mathrm{d}\vec{k}$ representing the shifting of the ends of the unit-vectors $\vec{i},\vec{j},\vec{k}$. We introduce them in the following expression which becomes, after rearrangement of the terms:

$$x\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}+y\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}+z\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}=(\omega_y z-y\omega_z)\vec{i}+(\omega_z x-z\omega_x)\vec{j}+(\omega_x y-x\omega_y)\vec{k}=\vec{\omega}\times\vec{r} \tag{9.3.701}$$

by definition of the vector cross product (see section Vector Calculus page 1830). The absolute velocity of the point P is therefore expressed as the "composition law of velocities":

$$\boxed{\vec{v}_a=\vec{v}_e+\vec{v}_r+\vec{\omega}\times\vec{r}} \tag{9.3.702}$$

we see that in the particular case where the moving reference frame only undergoes a translation such that $\vec{\omega}=\vec{0}$, we fall back on:

$$\vec{v}_a=\vec{v}_e+\vec{v}_r \tag{9.3.703}$$

that is the characteristic of the Galilean transformation and then we say that the reference frame are in "relative translations".

Remark

If we focus only on the terms $\vec{v}_e$ and $\vec{\omega}$ of the moving reference frame then we get what we name the "Bour formula".

Proceeding in the same way as the search for the absolute velocity it comes, by derivating the prior previous boxed relation:

$$\vec{a}_a=\vec{a}_e+\frac{\mathrm{d}\vec{v}_r}{\mathrm{d}t}+\frac{\mathrm{d}}{\mathrm{d}t}(\vec{\omega}\times\vec{r}) \tag{9.3.704}$$

with:

$$\begin{aligned}\frac{\mathrm{d}(\vec{\omega}\times\vec{v})}{\mathrm{d}t}&=\frac{\mathrm{d}\left[(\omega_y z-y\omega_z)\vec{i}+(\omega_z x-z\omega_x)\vec{j}+(\omega_x y-x\omega_y)\vec{k}\right]}{\mathrm{d}t}\\&=\frac{\mathrm{d}\omega_y}{\mathrm{d}t}z\vec{i}+\omega_y\frac{\mathrm{d}z}{\mathrm{d}t}\vec{i}+\omega_y z\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}-\frac{\mathrm{d}\omega_z}{\mathrm{d}t}y\vec{i}-\omega_z\frac{\mathrm{d}y}{\mathrm{d}t}\vec{i}-\omega_z y\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}\\&+\frac{\mathrm{d}\omega_z}{\mathrm{d}t}x\vec{j}+\omega_z\frac{\mathrm{d}x}{\mathrm{d}t}\vec{j}+\omega_z x\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}-\frac{\mathrm{d}\omega_x}{\mathrm{d}t}z\vec{j}-\omega_x\frac{\mathrm{d}z}{\mathrm{d}t}\vec{j}-\omega_x z\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}\\&+\frac{\mathrm{d}\omega_x}{\mathrm{d}t}y\vec{k}+\omega_x\frac{\mathrm{d}y}{\mathrm{d}t}\vec{k}+\omega_x y\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}-\frac{\mathrm{d}\omega_y}{\mathrm{d}t}x\vec{k}-\omega_y\frac{\mathrm{d}x}{\mathrm{d}t}\vec{k}-\omega_y x\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\end{aligned} \tag{9.3.705}$$

If we regroup the terms:

$$\left(\omega_y\frac{\mathrm{d}z}{\mathrm{d}t}\vec{i}-\omega_z\frac{\mathrm{d}y}{\mathrm{d}t}\vec{i}\right)+\left(\omega_z\frac{\mathrm{d}x}{\mathrm{d}t}\vec{j}-\omega_x\frac{\mathrm{d}z}{\mathrm{d}t}\vec{j}\right)+\left(\omega_x\frac{\mathrm{d}y}{\mathrm{d}t}\vec{k}-\omega_y\frac{\mathrm{d}x}{\mathrm{d}t}\vec{k}\right)=\vec{\omega}\times\vec{v}_r \tag{9.3.706}$$

If we regroup the terms:

$$\left(\frac{\mathrm{d}\omega_y}{\mathrm{d}t}z\vec{i}-\frac{\mathrm{d}\omega_z}{\mathrm{d}t}y\vec{i}\right)+\left(\frac{\mathrm{d}\omega_z}{\mathrm{d}t}x\vec{j}-\frac{\mathrm{d}\omega_x}{\mathrm{d}t}z\vec{j}\right)+\left(\frac{\mathrm{d}\omega_x}{\mathrm{d}t}y\vec{k}-\frac{\mathrm{d}\omega_y}{\mathrm{d}t}x\vec{k}\right)=\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r} \tag{9.3.707}$$

If we regroup the terms:

$$\begin{aligned}&\left(\omega_y z\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}-\omega_z y\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}\right)+\left(\omega_z x\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}-\omega_x z\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}\right)+\left(\omega_x y\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}-\omega_y x\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\right)\\&=(\omega_y z-\omega_z y)\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}+(\omega_z x-\omega_x z)\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}+(\omega_x y-\omega_y x)\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\end{aligned} \tag{9.3.708}$$

and we have:

$$\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}=(\vec{j}\omega_z-\vec{k}\omega_y)\quad\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}=(\vec{k}\omega_x-\vec{i}\omega_z)\quad\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}=(\vec{k}\omega_y-\vec{j}\omega_x) \tag{9.3.709}$$

Therefore:

$$\begin{aligned}&(\omega_y z-\omega_z y)(\vec{j}\omega_z-\vec{k}\omega_y)+(\omega_z x-\omega_x z)(\vec{k}\omega_x-\vec{i}\omega_z)+(\omega_x y-\omega_y x)(\vec{i}\omega_y-\vec{j}\omega_x)\\&=(\omega_z x-\omega_x z)(-\vec{i}\omega_z)+(\omega_x y-\omega_y x)(\vec{i}\omega_y)\\&+(\omega_y z-\omega_z y)(\vec{j}\omega_z)+(\omega_x y-\omega_y x)(-\vec{j}\omega_x)\\&+(\omega_y z-\omega_z y)(-\vec{k}\omega_y)+(\omega_z x-\omega_x z)(\vec{k}\omega_x)\\&=\left[\omega_y(\omega_x y-\omega_y x)-\omega_z(\omega_z x-\omega_x z)\right]\vec{i}+\left[\omega_z(\omega_y z-\omega_z y)-\omega_x(\omega_x y-\omega_y x)\right]\vec{j}\\&+\left[\omega_x(\omega_z x-\omega_x z)-\omega_y(\omega_y z-\omega_z y)\right]\vec{k}\\&=\vec{\omega}\times(\vec{\omega}\times\vec{r})\end{aligned} \tag{9.3.710}$$

Finally:

$$\vec{a}_a=\vec{a}_e+\frac{\mathrm{d}\vec{v}_r}{\mathrm{d}t}+\vec{\omega}\times\vec{v}_r+\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}+\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.711}$$

but (!) let us recall that:

$$\vec{v}_r=\left(\frac{\mathrm{d}x}{\mathrm{d}t}\vec{i}+\frac{\mathrm{d}y}{\mathrm{d}t}\vec{j}+\frac{\mathrm{d}z}{\mathrm{d}t}\vec{k}\right) \tag{9.3.712}$$

Hence:

$$\begin{aligned}\frac{\mathrm{d}\vec{v}_r}{\mathrm{d}t}&=\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{d}x}{\mathrm{d}t}\vec{i}+\frac{\mathrm{d}y}{\mathrm{d}t}\vec{j}+\frac{\mathrm{d}z}{\mathrm{d}t}\vec{k}\right)\\&=\left(\frac{\mathrm{d}^2x}{\mathrm{d}t^2}\vec{i}+\frac{\mathrm{d}^2y}{\mathrm{d}t^2}\vec{j}+\frac{\mathrm{d}^2z}{\mathrm{d}t^2}\vec{k}\right)+\left(\frac{\mathrm{d}x}{\mathrm{d}t}\frac{\mathrm{d}\vec{i}}{\mathrm{d}t}+\frac{\mathrm{d}y}{\mathrm{d}t}\frac{\mathrm{d}\vec{j}}{\mathrm{d}t}+\frac{\mathrm{d}z}{\mathrm{d}t}\frac{\mathrm{d}\vec{k}}{\mathrm{d}t}\right)\\&=\vec{a}_r+\vec{\omega}\times\vec{v}_r\end{aligned} \tag{9.3.713}$$

The absolute acceleration or "composition law of accelerations" or "acceleration transformation formula" is then expressed as:

$$\boxed{\vec{a}_a=\vec{a}_e+\vec{a}_r+2\vec{\omega}\times\vec{v}_r+\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}+\vec{\omega}\times(\vec{\omega}\times\vec{r})} \tag{9.3.714}$$

The term:

$$\vec{a}_{\text{cor.}}=2\vec{\omega}\times\vec{v}_r \tag{9.3.715}$$

is named the "Coriolis acceleration" (∼11820 according to holocene calendar) and the term $\vec{\omega}\times(\vec{\omega}\times\vec{r})$ is simply the expression of the centripetal acceleration in this particular case.

The physical acceleration $\vec{a}_a$ due to what observers in the inertial frame name "real external forces" on the object is, therefore, not simply the acceleration $\vec{a}_e+\vec{a}_r$ seen by observers in the rotational frame, but has several additional geometric acceleration terms associated with the rotation of moving rotational frame.

The second Newton's law $\vec{F}=m\vec{a}$ must have all the terms contained in the general equation above. For an observer in a stationary system, this law is then:

$$\boxed{\vec{F}=m\vec{a}_e+m\vec{a}_r+2m\vec{\omega}\times\vec{v}_r+m\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}+m\vec{\omega}\times(\vec{\omega}\times\vec{r})} \tag{9.3.716}$$

If we rewrite it as the point of view of the observer at the origin of the rotating and moving reference frame, we get obviously:

$$m\vec{a}_e+m\vec{a}=\vec{F}_r-2m\vec{\omega}\times\vec{v}_r-m\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}-m\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.717}$$

The set:

$$\vec{F}_{\text{fict}}=-2m\vec{\omega}\times\vec{v}_r-m\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}-m\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.718}$$

is the fictitious force used by the observer in the moving rotating frame to get the correct behaviour of the object from Newton's laws.

Above, the first term is the "Coriolis force", the second term is the "Euler Force", and the third term is the "centrifugal (fictional) force".

Indeed in scalar form we recognize in the third term:

$$m\omega^2 r = m\left(\frac{v}{r}\right)^2 r = m\frac{v^2}{r} = a_n \tag{9.3.719}$$

The Euler force is the fictitious tangential force that is felt in reaction to any angular acceleration. That reactive acceleration is the "Euler acceleration" also known as "azimuthal acceleration" or "transverse acceleration". In other words, it is an acceleration that appears when a non-uniformly rotating reference frame is used for analysis of motion and there is variation in the angular velocity of the reference frame's axes. The Euler force is typically felt by a person riding a merry-go-round. As the ride starts, the Euler force will be the apparent force pushing the person to the back of the horse, and as the ride comes to a stop, it will be the apparent force pushing the person towards the front of the horse. The Euler force is perpendicular to the centrifugal (fictional) force and is in the plane of rotation.

If the point P is rigidly connected to the moving reference frame, an observer in this system will see no movement, therefore no acceleration $\vec{a}_r$. So we are dealing with a system of forces in equilibrium. The dynamics problem is then reduced to a static problem. This is the "d'Alembert's principle of inertial forces".

✍**Example:**

We want to study the movement of a frictionless ball or puck on a turntable.

Taking into account Coriolis and centrifugal (fictional) forces, the fictitious force in the rotating frame of the turntable is as we have proved above:

$$\vec{F}_{\text{fict}} = m a_{\text{fict}} = -m\left(\vec{\omega}\times(\vec{\omega}\times\vec{r}) + 2\vec{\omega}\times\vec{v}_r\right) \tag{9.3.720}$$

The coordinate system is defined with respect to the center of the turntable, with the z-axis pointing out of its plane. Thus:

$$\vec{\omega} = \begin{pmatrix} 0 \\ 0 \\ \omega \end{pmatrix} \qquad \vec{r} = \begin{pmatrix} x \\ y \\ 0 \end{pmatrix} \qquad \vec{v}_r = \begin{pmatrix} \dot{x} \\ \dot{y} \\ 0 \end{pmatrix} \tag{9.3.721}$$

and hence:

$$\vec{\omega}\times(\vec{\omega}\times\vec{r}) = \begin{pmatrix} -x\omega^2 \\ -y\omega^2 \\ 0 \end{pmatrix} \tag{9.3.722}$$

and:

$$\vec{\omega}\times\vec{v}_r = \begin{pmatrix} -\dot{y}\omega \\ \dot{x}\omega \\ 0 \end{pmatrix} \tag{9.3.723}$$

Therefore we find the fictitious acceleration:

$$\vec{a}_{\text{fict}} = -\vec{\omega} \times (\vec{\omega} \times \vec{r}) - 2\vec{\omega} \times \vec{v}_r = \begin{pmatrix} x\omega^2 + 2\dot{y}\omega \\ y\omega^2 - 2\dot{x}\omega \\ 0 \end{pmatrix} \quad (9.3.724)$$

Splitting this up into components, we see that:

$$\begin{gathered} \ddot{x} = x\omega^2 + 2\dot{y}\omega \\ \ddot{y} = y\omega^2 - 2\dot{x}\omega \end{gathered} \quad (9.3.725)$$

Now consider the trick consisting to involve a fake complex coordinates $q = x + \mathrm{i}y$. We multiply:

$$\ddot{y} = y\omega^2 - 2\dot{x}\omega \quad (9.3.726)$$

by i and add:

$$\ddot{x} = x\omega^2 + 2\dot{y}\omega \quad (9.3.727)$$

So we get:

$$\ddot{x} + \mathrm{i}\ddot{y} + 2\omega\mathrm{i}(\dot{x} + \mathrm{i}\dot{y}) - \omega^2(x + \mathrm{i}y) = 0 \quad (9.3.728)$$

The auxiliary complex variable q then occurs naturally in the unique differential equation, as follows:

$$\ddot{q} + 2\omega\mathrm{i}\dot{q} - \omega^2 q = 0 \quad (9.3.729)$$

We have proved in the section of Differential and Integral Calculus (see page 1610) that the homogeneous solution of this differential equation was depending the discriminant of the polynomial. So here we have:

$$\Delta = (2\omega\mathrm{i})^2 - 4(-\omega^2) = -4\omega^2 + 4\omega^2 = 0 \quad (9.3.730)$$

Therefore the homogeneous solution is according to what we have proved in the section of Differential and Integral Calculus:

$$q_h = (Ct + c^{te})e^{K(t+\tau)} \quad (9.3.731)$$

with:

$$K_{1,2} = K = \frac{-2\mathrm{i}\omega \pm \Delta}{2} = \frac{-2\mathrm{i}\omega}{2} = -\mathrm{i}\omega \quad (9.3.732)$$

Following initial conditions, as at time $t = 0$ we have $x = 0$ and $y = 0$ it is same for q.

Then we see immediately that we must have:

$$\tau = 0 \quad \text{and} \quad c^{te} = 0 \quad (9.3.733)$$

Then it remains:

$$q_h = Cte^{-\mathrm{i}\omega t} = Ct\cos(\omega t) - Ct\mathrm{i}\sin(\omega t) \quad (9.3.734)$$

and as $q = x + \mathrm{i}y$ we have by correspondence:

$$\begin{aligned} x(t) &= Ct\cos(\omega t) \\ y(t) &= -Ct\sin(\omega t) \end{aligned} \qquad (9.3.735)$$

From the initial conditions it is quite obvious that:

$$\begin{aligned} x(t) &= v_0 t\cos(\omega t) \\ y(t) &= -v_0 t\sin(\omega t) \end{aligned} \qquad (9.3.736)$$

And we have only a one component initial velocity $v_0 = v_{0x} = v_{0y}$ as their is not privileged directions for our reference frame in the turntable of the axis can always be oriented in the direction of the initial velocity.

With Maple™ 4.00b we get:

```
>plot([t*cos(t),-t*sin(t),t=0..6]);
```

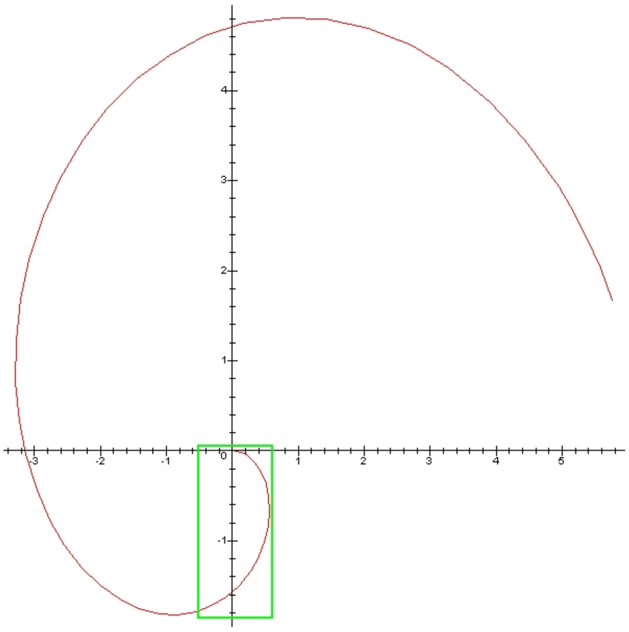


Figure 9.77: **Coriolis force trajectory of moving item on a turntable**

We have put on evidence in green the part of the trajectory that most of people know or have seen (even if the remaining part not highlighted really also exists as the reader can see it on many videos on YouTube!!!).

9.3.9.1 Coriolis force and deflection magnitude

Since almost all our observations are made on Earth, that is to say in a moving frame in the Universe, the Coriolis force can be detected.

The study of the motion of a body in relation to the Earth is one of the most interesting applications of the composition law proved above. The Earth has an angular velocity (assumed constant!) whose direction is that of the axis of rotation of the Earth. Let us denote by $\vec{g}_0$ the acceleration of gravity measured at a point A on the surface of the Earth if the latter did not rotate. $\vec{g}_0$ corresponds then to $\vec{a}_a$.

As we just proved it, we have:

$$\vec{a}_e+\vec{a}_r=\vec{a'}=\vec{a}_a-2\vec{\omega}\times\vec{v}_r-\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}-\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.737}$$

where we suppose for the Earth that (it's rotation speed does not change):

$$\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t}\times\vec{r}\cong\vec{0} \tag{9.3.738}$$

Therefore it remains:

$$\vec{a}_e+\vec{a}_r=\vec{a'}=\vec{a}_a-2\vec{\omega}\times\vec{v}_r-\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.739}$$

also sometimes denoted:

$$\vec{a}_{\text{rel}}=\vec{a}_{\text{abs}}-2\Omega\times\vec{v}_{\text{rel}}-\Omega\times(\Omega\times\vec{r}) \tag{9.3.740}$$

where $-2\Omega\times\vec{v}_{\text{rel}}$ represents the Coriolis force (per unit mass) deflecting the motion to its right and $-\Omega\times(\Omega\times\vec{r})$ the centrifugal acceleration, directed outwards, moving the mobile away from the Earth's axis of rotation.

We first consider the obvious case of a body initially at rest or moving very slowly so that the Coriolis term is zero or negligible compared to last term. The acceleration that we measure in this case is name the "effective acceleration" of gravity, and we denote it by $\vec{g}$.

Then it follows:

$$\vec{g}=\vec{g}_0-\vec{\omega}\times(\vec{\omega}\times\vec{r}) \tag{9.3.741}$$

Assuming that the Earth is a sphere (actually the shape is slightly away as we will see in the section Astronomy) and that there is no local anomalies, we can estimate that $\vec{g}_0$ is directed towards the center of the Earth. The second term $-\vec{\omega}\times(\vec{\omega}\times\vec{r})$ being the centrifugal acceleration is directed outwardly.

Since $\vec{g}$ is the sum of $\vec{g}_0$ and the centrifugal acceleration, the direction of $\vec{g}$, named sometimes the "vertical direction", deviates actually slightly from the radial direction; this is determined experimentally by a plumb line or also by a liquid recipient as they always maintained in equilibrium with their surface perpendicular to $\vec{g}$.

The magnitude of the centrifugal acceleration is:

$$\|\vec{\omega}\times(\vec{\omega}\times\vec{r})\| \cong \omega^2 r \cong 3.39\cdot 10^{-2}\,[\mathrm{m}\cdot\mathrm{s}^{-2}] \qquad (9.3.742)$$

where r is Earth's radius.

So when we see the value we understand why it can be neglected in most experiments! However explains most of the observed variations in the value of gravity with latitude!!

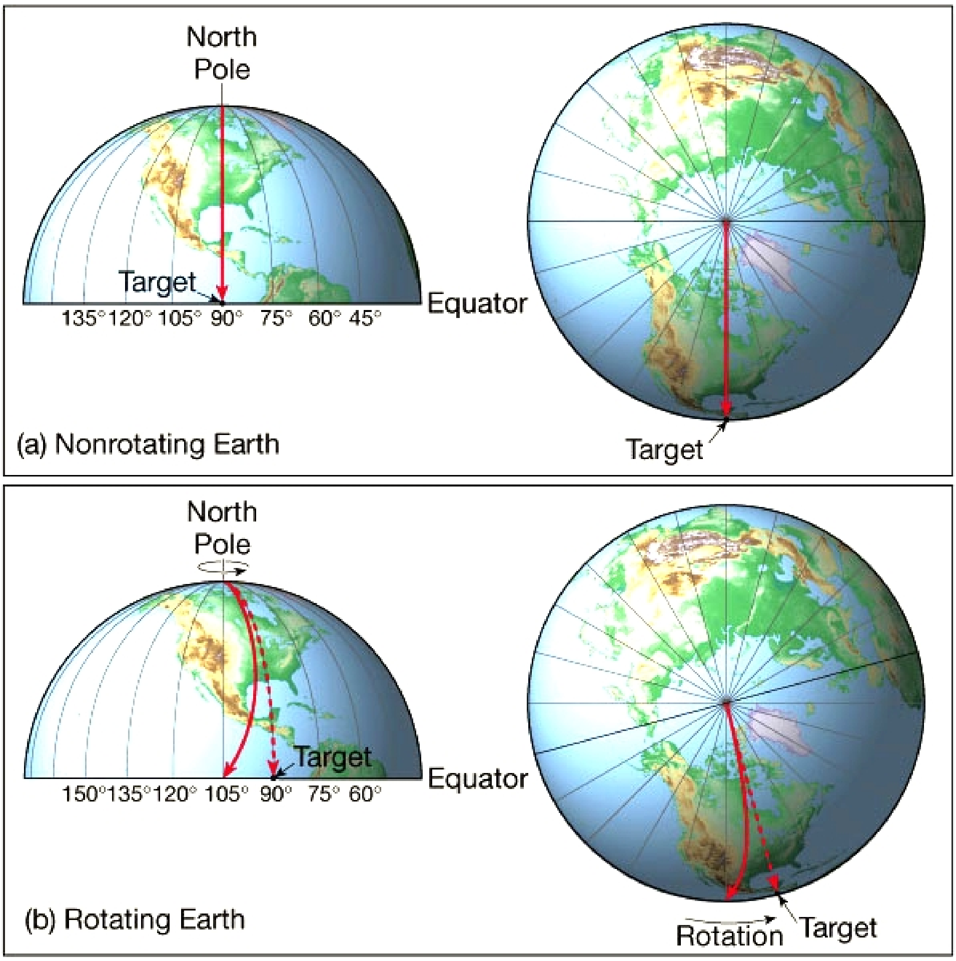
It also obvious as the centrifugal (fictional) force involves the cross product (and the therefore the sinus angle) that the latter is maximum at the equation and minimum at the poles. The centrifugal acceleration also decreases from the equator to the poles because the radius of the Earth is not constant (the Earth is flattened at the poles).

Remark

The gradient of the centrifugal acceleration has the effect of slightly moving the radial direction of a body that falls freely: the movement is oriented south in the northern hemisphere and to the north in the southern hemisphere.

Let us consider now the Coriolis term. In the case of a falling body, the velocity $\vec{r}_r$ is directed downward. Moreover, as $\vec{\omega}$ lies along the axis of the Earth, $\omega\times\vec{r}_r$ or oriented west. The term Coriolis term $-2m\vec{\omega}\times\vec{v}_r$ is then directed to the east; the falling body will be deflected in that direction as show the figure below.

For a body falling in a parallel and tangential to the surface of the Earth plane, we have:



North
Pole
Target
135° 120° 105° 90° 75° 60° 45°
Equator
Target
(a) Nonrotating Earth
North
Pole

Equator
(b) Rotating Earth
Rotation
Target

Figure 9.78: Illustration of the Earth's Coriolis force

It is exactly this phenomenon that is observed in the case of cyclones (we will return on this more in detail during our study of meteorology in the section of Weather and Marine Engineering). A low pressure air zone (relative low pressure) would give radial converging air currents (winds) towards depression if the Earth did not rotate around its axis:

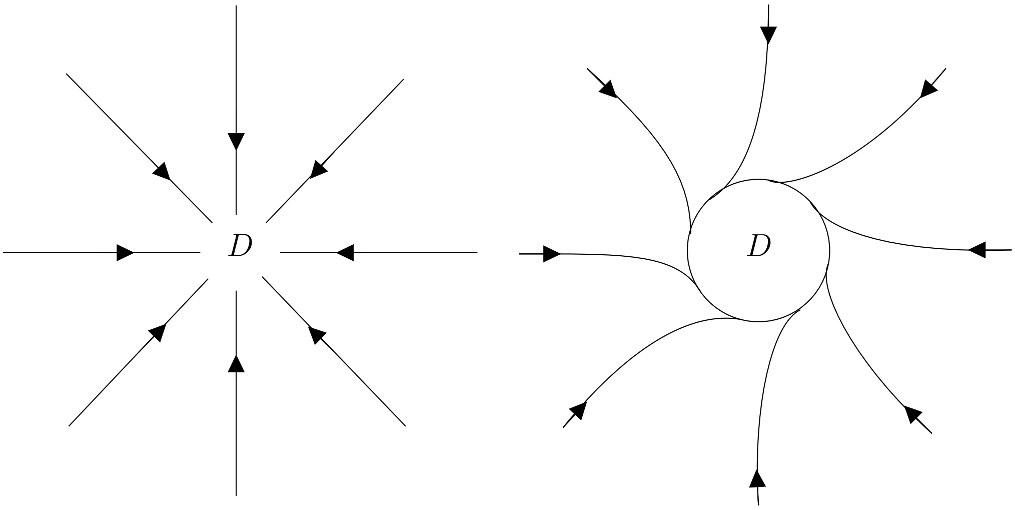

Figure 9.79: Generation of cyclones by the Coriolis force

The Coriolis force due to the rotation of the Earth therefore deflects the North-South winds towards the West and South-North winds East for an observer located at the North Pole. We see therefore the formation of cyclones turning in the counter-clockwise direction in the Northern Hemisphere and vice versa in the Southern hemisphere (due to the direction of the vector $\vec{\omega}$ in this part of the hemisphere).

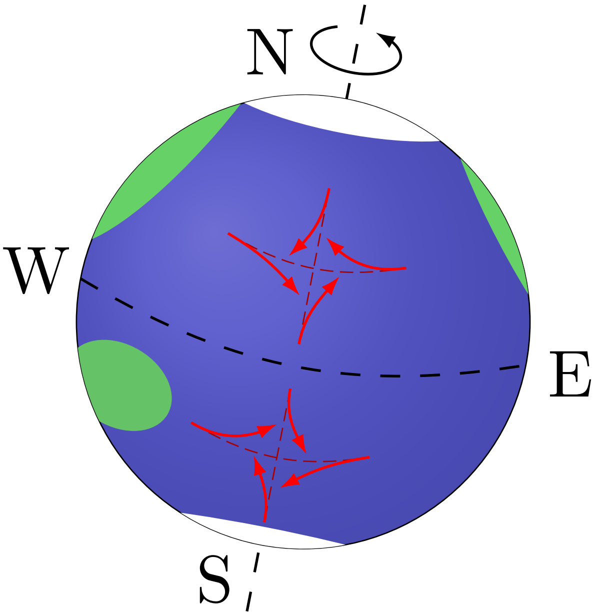

Figure 9.80: **North vs Southern Coriolis effect (author: Izaak Neutelings)**

As a second example, let consider the oscillations of a pendulum (that we will study in detail further below anyway!). For small amplitude oscillations, we can assume that the pendulum is in a horizontal trajectory. If we oscillates the pendulum initially in the North-South direction, the Coriolis force will deflect the pendulum to the right to an observer at the North Pole. In other words, the pendulum turns in the clockwise direction in the Northern Hemisphere and counter-clockwise in the Southern Hemisphere. This observed effect is zero at the equator (perfect parallelism between $\vec{r}$ and $\vec{\omega}$) and maximum to the Poles.

As a third example let us talk of the swirls that can be observed in the bathtub or sink. It is a legend that the latter rotates differently in different hemispheres. Because the speed and the mass involved are too small to be observable in such objects (see the numerical argument proof further below). In fact, the direction of rotation is due to imperfections (bumps) of the siphon. By cons, if you go in Ecuador, there are students who are happy to show you effect exists with a little experiment using a match. By moving 10 meters to the North or the South , they will show you the direction of rotation of the siphon changes depending on which hemisphere you are in but in fact this is fake a fake experiment[17]!

Ok now enough speak! Let us come back on pure calculations!!! So let us recall that:

$$\vec{a}_{\text{cor.}}=2\vec{\omega}\times\vec{v}_r \tag{9.3.743}$$

---

[17] Many videos can be found on YouTube

In scalar form this gives obviously:

$$a_{\text{cor.}}=\frac{\mathrm{d}v_{\text{cor.}}}{\mathrm{d}t}=2\omega v_r\sin(\phi) \tag{9.3.744}$$

If we assume that an air parcel, water parcel or any moving object moves at a constant speed v at given latitude ϕ, then the relation above can be integrated twice with respect to time to get the deflection magnitude x, of the horizontal deflection due to Coriolis. A first integration gives:

$$\frac{\mathrm{d}x_{\text{cor.}}}{\mathrm{d}t}=2\omega v_r\sin(\phi)t \tag{9.3.745}$$

So finally:

$$\boxed{\delta_{\text{cor.}}=x=\omega v_r\sin(\phi)t^2} \tag{9.3.746}$$

The justification for the oceanographer's observation that «*...something moving slow can be deflected more than something moving fast...*» can be deduced obviously from the latter relation.

We also define:

$$f=2\omega\sin(\phi) \tag{9.3.747}$$

as being the "Coriolis parameter" or "Coriolis frequency".

The "Rossby number" is a dimensionless ratio of the total acceleration to the Coriolis acceleration as given by:

$$R_0=\frac{a_a}{|2\omega v_r\sin(\phi)|} \tag{9.3.748}$$

The Rossby number is greater than 2.0 in the lower subtropics. In the middle latitudes the Rossby number is less than 0.1 on average. Values of the Rossby number in the middle latitudes are <0.05 in the mid troposphere.

And what about the corresponding force? We know we have:

$$\vec{F}=-2m\vec{\omega}\times\vec{v}_r \tag{9.3.749}$$

If we choose to track $1\,[\text{L}]$ of water falling vertically under gravity on a distance of $0.1\,[\text{m}]$ we have:

$$\begin{aligned}
m&=1\,[\text{kg}]\\
\phi&=\frac{\pi}{2}\\
\omega&=\frac{2\pi}{24\cdot 60\cdot 60}=7.27221\cdot 10^{-5}\,[\text{s}^{-1}]\\
v_r&=\sqrt{2mgh}=\sqrt{2\cdot 1\cdot 9.81\cdot 0.1}\cong 1.4\,[\text{m}\cdot\text{s}^{-1}]
\end{aligned} \tag{9.3.750}$$

where for recall ϕ is the latitude (so we take the pole!). Then the magnitude of the Coriolis force is in absolute value:

$$F_{\text{cor.}}=2m\omega v\sin(\phi)=2m\omega v=2\cdot 1\cdot 1.4\cdot 7.27221\cdot 10^{-5}\cong 0.0002\,[\text{N}] \tag{9.3.751}$$

So we see that even at the north pole this would not be enough to see water rotate only because of Coriolis force. So we let you imagine at the Equator where $\phi\cong 0$ what is the magnitude of the Coriolis force. Then the videos that we can see on Internet are just fake experimental pseudo proofs!

9.3.9.1.1 Coriolis deviation of free falling objects

Let us calculate the deflection of a particle thrown up to reach a maximum height z_0, and that of a particle dropped from rest from the same height, due to the Coriolis force.

The Coriolis force appears as we have just prove as extra force term in a rotating frame (such as one fixed to Earth), of the form:

$$\vec{F}_C = -2m\vec{\omega} \times \vec{v} \tag{9.3.752}$$

For a particle moving "up" in the Earth's frame (relatively to the ground(, this force has a horizontal direction (by construction of the cross product!

If we choose a coordinate system fixed and tangential to the ground of the Earth, with the z axis pointing "up", the x axis pointing north, and the y axis pointing West, the Earth's angular velocity will have components :

$$\vec{\omega} = \hat{x}\omega\cos(\lambda) + \hat{z}\omega\sin(\lambda) \tag{9.3.753}$$

where λ is the latitude angle (zero at the equator, $90°$ at the North pole, and $30°27'\text{N}$ at Baton Rouge).

Remembering that the cross product is given by:

$$\vec{x} \times \vec{y} = \begin{pmatrix} x_2y_3 - x_3y_2 \\ x_3y_1 - x_1y_3 \\ x_1y_2 - x_2y_1 \end{pmatrix} \tag{9.3.754}$$

So if we have only the third component of the second vector that is non-zero, and only the first and third component of the first vector that are non-zero, this reduces to:

$$\vec{x} \times \vec{y} = \begin{pmatrix} x_2y_3 - x_3y_2 \\ x_3y_1 - x_1y_3 \\ x_1y_2 - x_2y_1 \end{pmatrix} = \begin{pmatrix} 0 \\ -x_1y_3 \\ 0 \end{pmatrix} \tag{9.3.755}$$

Therefore:

$$\vec{F}_C = -2m\vec{\omega} \times \vec{v} = -2m\omega v_z(\hat{x}\cos(\lambda) + \hat{z}\sin(\lambda)) \times \hat{z} = 2m\omega\cos(\lambda)v_z\hat{y} \tag{9.3.756}$$

so the Coriolis force is only in the East-West direction, is maximum at the Equator, and is in the same direction on both hemispheres.

The motion in the vertical direction is only affected by gravity, so:

$$z(t) = z_0 + v_{0z}t - \frac{1}{2}gt^2 \tag{9.3.757}$$

and:

$$v_z = v_{0z} - gt \tag{9.3.758}$$

as usual. The acceleration in the y direction, however, is:

$$m\ddot{y} = 2m\omega\cos(\lambda)\,(v_{0z} - gt) \tag{9.3.759}$$

and direct integration leads to:

$$y(t)=y_0+v_{0y}t+2\omega\cos\lambda\left(\frac{1}{2}v_{0z}t^2-\frac{1}{6}gt^3\right) \tag{9.3.760}$$

If the particle is thrown from the ground with a vertical velocity upwards, then it will reach its maximum height at time $t=v_{0z}/g$, and the height will be $z_{\text{max}}=v_{0z}^2/2g$. The particle returns to the ground at time $t=2v_{0z}/g$, and the total horizontal deflection will be:

$$\begin{aligned}\Delta y&=2\omega\cos(\lambda)\left(\frac{v_{0z}}{2}\left(\frac{2v_{0z}}{g}\right)^2-\frac{g}{6}\left(\frac{2v_{0z}}{g}\right)^3\right)=\frac{4}{3}\omega\cos(\lambda)\frac{v_{0z}^3}{g^2}=\sqrt{2}\frac{8}{3}\cos(\lambda)z_{\text{max}}\sqrt{\frac{\omega^2 z_{\text{max}}}{g}}\\&=\sqrt{2}\frac{8}{3}\cos(\lambda)z_{\text{max}}\omega\sqrt{\frac{z_{\text{max}}}{g}}\end{aligned} \tag{9.3.761}$$

And now the most famous case! If the particle is dropped from rest from the same height z_{max}, then $v_{0z}=0$. The particle will reach the ground at time $t=\sqrt{2z_{\text{max}}/g}$, and the total horizontal deflection will be:

$$\Delta y=-\frac{1}{3}\omega\cos(\lambda)gt^3=-\frac{1}{3}\omega\cos(\lambda)g\left(\frac{2z_{\text{max}}}{g}\right)^{3/2}=-\sqrt{2}\frac{2}{3}\cos(\lambda)z_{\text{max}}\sqrt{\frac{\omega^2 z_{\text{max}}}{g}} \tag{9.3.762}$$

More often denoted:

$$\boxed{\Delta=\cos(\lambda)\frac{2\omega_0 h_0^{\frac{3}{2}}\sqrt{2}}{3\sqrt{g}}} \tag{9.3.763}$$

Remark

In reality, the motion of the particle in the Earth rotating coordinates is affected both by the Coriolis force $-2m\vec{\omega}\times\vec{v}$ and by the centrifugal force $-m\vec{\omega}\times\vec{\omega}\times\vec{r}$, which has both horizontal and vertical components. Also, once there is a velocity horizontal velocity in the east-west direction (proportional to ω), the Coriolis force will also have a component in the north-south direction (proportional to ω^2). However, since the Earth's velocity is small compared to the quantities in the system ($\omega R^2 \ll g$), these corrections are even smaller than the the corrections we calculated, proportional to ω.

An object falling straight downward will be slightly deflected due to Earth's rotation. It is the Coriolis effect that arises from vertical motion. Several experiments have confirmed it since the 118th century (holocene calendar):

	Drop height	**Deflection**	**Expected**
Giovanni Battista Guglielmini, 11791 Torre degli Asinelli, Bologna, Italy	78 m	16 mm	10.7 mm

9.3.9.2 Eötvös effect

The "Eötvös effect" is the change in measured Earth's gravity caused by the change in centrifugal acceleration resulting from eastbound or westbound velocity. When moving eastbound, the object's angular velocity is increased (in addition to Earth's rotation), and thus the centrifugal force also increases, causing a perceived reduction in gravitational force.

In the early 11900s (holocene calendar), a German team from the Geodetic Institute of Potsdam carried out gravity measurements on moving ships in the Atlantic, Indian, and Pacific oceans. While studying their results, the Hungarian nobleman and physicist Baron Roland von Eötvös (Loránd Eötvös) noticed that the readings were lower when the boat moved eastwards, higher when it moved westward. He identified this as primarily a consequence of Earth's rotation. In 11908 (holocene calendar), new measurements were made in the Black Sea on two ships, one moving eastward and one westward. The results substantiated Eötvös' claim!

Geodesists use the following formula to correct for velocity relative to Earth during a gravimetric run (see proof further below):

$$a_r = 2\Omega u \cos(\phi) + \frac{u^2+v^2}{R} \qquad (9.3.764)$$

Here:

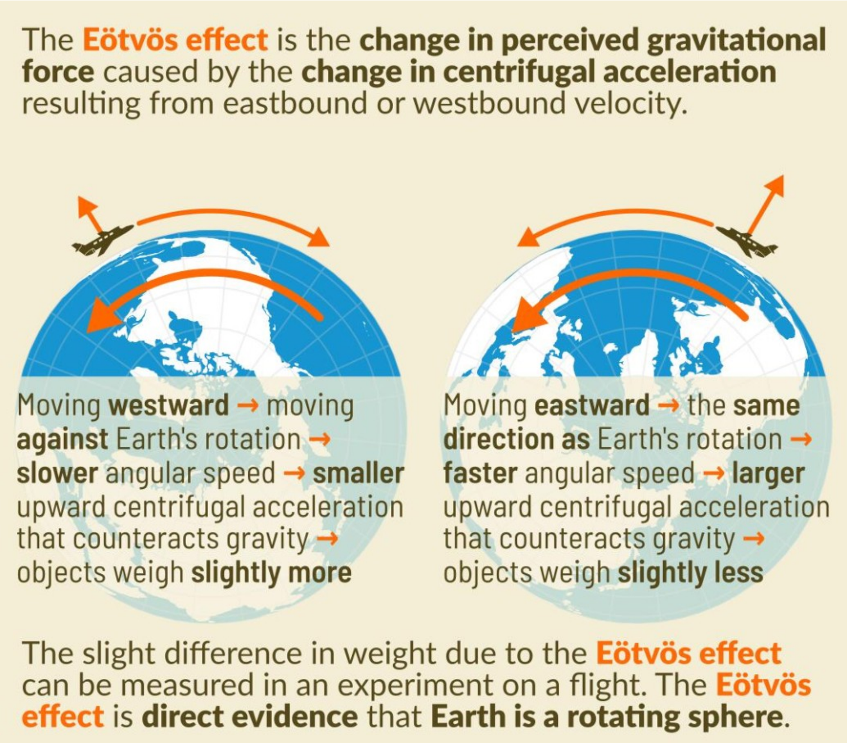
- a_r is the relative acceleration
- Ω is the rotation rate of the Earth
- u is the velocity in longitudinal direction (East-West)
- ϕ is the latitude where the measurements are taken
- v is the velocity in latitudinal direction (North-South)
- R is the radius of the Earth

The first term in the formula, $2\Omega u\cos(\phi)$, corresponds to the Eötvös effect. The second term is a refinement that under normal circumstances is much smaller than the Eötvös effect and that represents the required centrifugal acceleration for the ship to follow the curvature of the Earth. It is independent of both the Earth's rotation and the direction of motion (under normal conditions this term is negligible).

The relation above is the result of a simple reasoning. The attraction force of the Earth is the resultant of two forces: the gravitational force, according to Newton's law and the centrifugal force caused by the Earth rotation (for modern measurements of Earth's rotation and its variations see [102] and [484]). Since the masses on the Earth's surface are uniform distributed and the angular velocity at which the Earth rotates are constant, the weight of the objects at rest on the Earth's surface is a constant. In the case of moving objects the situation is different. Since the Earth's rotation is from west to east, the centrifugal force acting on a moving object is greater if its motion on Earth's surface is towards the east than towards the west. Therefore the specific weight of a moving eastwards object is decreasing, while the specific weight of a moving westwards object is increasing.

Coriolis is a conservation of angular momentum consideration when objects move North/South across a spinning sphere. As you move away from the equator latitudinally, the same angular rate of rotation around the Earth's results in a different velocity in the East/West component, and the effects of this difference is the Coriolis Effect. Were the Earth a cylinder instead of a sphere, there'd be no Coriolis Force!

Eötvös on the other hand is a centrifugal force/orbital mechanics problem. Eötvös would still occur on a cylinder, where Coriolis would not.



The Eötvös effect is the change in perceived gravitational force caused by the change in centrifugal acceleration resulting from eastbound or westbound velocity.
Moving westward → moving against Earth's rotation → slower angular speed → smaller upward centrifugal acceleration that counteracts gravity → objects weigh slightly more
Moving eastward → the same direction as Earth's rotation → faster angular speed → larger upward centrifugal acceleration that counteracts gravity → objects weigh slightly less
The slight difference in weight due to the Eötvös effect can be measured in an experiment on a flight. The Eötvös effect is direct evidence that Earth is a rotating sphere.

Figure 9.81: Eötvös effect illustrated (source: flatearth.ws)

Proof 9.8.3. The Eötvös effect describes the change in perceived gravitational acceleration for an object moving relative to the surface of the rotating Earth. When an object moves eastward, its angular velocity around the Earth's axis increases, which increases the outward centrifugal force and decreases its apparent weight. Moving westward has the opposite effect. To derive the complete Eötvös formula, we must account for both the Earth's rotation and the curvature of the Earth's surface.

Let us define the parameters for an object moving on the surface of a spherical Earth:

- R : Radius of the Earth.
- Ω : Angular velocity of the Earth's rotation.
- ϕ : Geodetic latitude of the object.
- v_E : The object's velocity component in the Eastward direction.
- v_N : The object's velocity component in the Northward direction.

Before the object moves, it is simply resting on the Earth's surface at latitude ϕ. It travels in a circle around the Earth's axis of rotation.

The distance from the object to the axis of rotation is:

$$r_\perp = R\cos(\phi) \tag{9.3.765}$$

The centrifugal acceleration directed strictly outward from the axis of rotation is:

$$a_{c,0} = \Omega^2 r_\perp = \Omega^2 R\cos(\phi) \tag{9.3.766}$$

Because gravimeters and scales measure forces relative to the local vertical (perpendicular to the Earth's surface), we only care about the radial component of this centrifugal acceleration, pointing straight up from the ground. We project this vector onto the local vertical by multiplying by $\cos(\phi)$:

$$a_{r,0} = a_{c,0}\cos(\phi) = \Omega^2 R\cos^2(\phi) \tag{9.3.767}$$

This baseline outward radial acceleration is already subtracted from Earth's raw gravitational pull[18] to give the standard local gravitational acceleration g that we measure at rest.

Now, let the object move eastward with a velocity v_E. This motion increases the object's total angular velocity around the Earth's axis.

The additional angular velocity due to v_E is the velocity divided by the radius of its circular path:

$$\omega_{\text{extra}} = \frac{v_E}{R\cos(\phi)} \tag{9.3.768}$$

The total angular velocity of the object around the Earth's axis is now:

$$\omega_{\text{tot.}} = \Omega + \frac{\nu_E}{R\cos(\phi)} \tag{9.3.769}$$

---

[18] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

We substitute this new angular velocity into the formula for outward radial centrifugal acceleration:

$$a_{r,\text{new}} = \omega_{\text{tot.}}^2 R\cos^2(\phi) = \left(\Omega + \frac{v_E}{R\cos(\phi)}\right)^2 R\cos^2(\phi) \tag{9.3.770}$$

Expanding the squared term:

$$a_{r,\text{new}} = \left(\Omega^2 + \frac{2\Omega v_E}{R\cos(\phi)} + \frac{v_E^2}{R^2\cos^2(\phi)}\right) R\cos^2(\phi) \tag{9.3.771}$$

Distributing $R\cos^2(\phi)$:

$$a_{r,\text{new}} = \Omega^2 R\cos^2(\phi) + 2\Omega v_E\cos(\phi) + \frac{v_E^2}{R} \tag{9.3.772}$$

If the object also moves northward (or southward) with velocity v_N, it is traveling along a meridian. Because the Earth is curved, moving along its surface at velocity v_N forces the object into a circular path of radius R.

This requires a centripetal force to keep it grounded. From the perspective of the object, this manifests as an additional outward centrifugal acceleration purely due to following the Earth's curvature:

$$a_{r,N} = \frac{v_N^2}{R} \tag{9.3.773}$$

The Eötvös acceleration a_r is defined as the change in the outward vertical acceleration caused by the object's motion. To find this, we sum the new radial accelerations and subtract the baseline radial acceleration of an object at rest:

$$\begin{aligned} a_r &= \text{Total outward acceleration in motion} - \text{Outward acceleration at rest} \\ &= (a_{r,\text{new}} + a_{r,N}) - a_{r,0} \end{aligned} \tag{9.3.774}$$

Substitute the derived expressions:

$$a_r = \left(\Omega^2 R\cos^2(\phi) + 2\Omega v_E\cos(\phi+)\frac{v_E^2}{R} + \frac{v_N^2}{R}\right) - \left(\Omega^2 R\cos^2(\phi)\right) \tag{9.3.775}$$

The $\Omega^2 R\cos^2(\phi)$ terms cancel out, leaving the final expression for the Eötvös acceleration:

$$a_r = 2\Omega v_E\cos(\phi) + \frac{v_E^2 + v_N^2}{R} \tag{9.3.776}$$

More often denoted:

$$\boxed{a_r = 2\Omega u\cos(\phi) + \frac{u^2 + v^2}{R}} \tag{9.3.777}$$

Because $v_E^2 + v_N^2 = v_s^2$ (where v_s is the total horizontal speed over the surface), the formula also sometimes written as:

$$a_r = 2\Omega u\cos(\phi) + \frac{v_s^2}{R} \tag{9.3.778}$$

■ Q.E.D.

To calculate what it takes for the internal weight of a gravimeter to be neutrally suspended when it is stationary with respect to the Earth, the Earth's rotation must be taken into account. At the equator, the velocity of Earth's surface is about 465 metres per second ($1,674\,[\mathrm{km}\cdot\mathrm{h}^{-1}]$). The amount of centripetal force required to cause an object to move along a circular path with a radius of $6,378$ kilometres (the Earth's equatorial radius), at $465\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$, is about 0.034 newtons per kilogram of mass. For a $10,000$-gram internal weight, that amounts to about 0.34 newtons. The amount of suspension force required is the mass of the internal weight (multiplied by the acceleration of gravity) minus those 0.34 newtons. In other words: any object corotating with the Earth at the equator has its measured weight reduced by 0.34%, thanks to the Earth's rotation.

When cruising at $10\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$ due East, the total velocity becomes $465+10=475\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$, which requires a centripetal force of about 0.0354 newtons per kilogram. Cruising at $10\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$ due West the net velocity is $465-10=455\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$, requiring about 0.0325 newtons per kilogram. So if the internal weight is neutrally suspended while cruising due East, after reversing course it will not be neutrally suspended any more: the apparent mass of the $10,000$-gram internal weight will increase by about 3 grams, and the spring of the gravimeter must extend some more to accommodate this greater weight.

Calculating the weight reduction when stationary with respect to the Earth: An object located at 60° latitude, co-moving with the Earth, is following a circular trajectory, with a radius of about $3,190$ kilometer, and a velocity of about $233\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$. That circular trajectory requires a centripetal force of about 0.017 newton for every kilogram of mass; 0.17 newton for the $10,000$ gram internal weight. At 60° latitude, the component that is perpendicular to the local surface (the local vertical) is half the total force. Hence, at 60° latitude, any object co-moving with the Earth has its weight reduced by about 0.08%, thanks to the Earth's rotation.

In high-performance meteorological models, this effect needs to be taken into account on a terrestrial scale. Air masses with significant velocity with respect to the Earth have a tendency to migrate to another altitude, and when the accuracy demands are strict this must be taken into account.

9.3.10 Oscillating Movements

Oscillation is the repetitive variation, typically in time, of some measure about a central value (often a point of equilibrium) or between two or more different states. The term "vibration" is precisely used to describe mechanical oscillation. Familiar examples of oscillation include a swinging pendulum and alternating current power.

All real-world oscillator systems are thermodynamically irreversible. This means there are dissipative processes such as friction or electrical resistance which continually convert some of the energy stored in the oscillator into heat in the environment. This is named "damping". Thus, oscillations tend to decay with time unless there is some net source of energy into the system.

There is an incredible amount of physical phenomena of this kind. We will deal in this subsection only on the classics from which the developments on more complex phenomena are based in this textbook (especially for the sections of Wave Quantum Physics and Mechanical Engineering).

For examples, oscillations occur not only in mechanical systems but also in dynamic systems in virtually every area of science: for example the beating human heart, business cycles in economics, predator–prey population cycles in ecology, geothermal geysers in geology, vibrating strings in musical instruments, periodic firing of nerve cells in the brain, and the periodic swelling of Cepheid variable stars in astronomy, molecular vibrations, quantum physics bonds.

We will limit here our study of oscillating movements to pendulums. The others situations will come step by step in the others chapters and respective sections of this textbook.

As far as we know there are 9 well-known pendulum study at school that are (order in which we will study): Newton's cradle, simple pendulum, physical pendulum clock, elastic pendulum, conical pendulum, torsion pendulum, Foucault pendulum, Huygens pendulum.

9.3.10.1 Newton's cradle

We will not take too much time to describe Newton's cradle. A photo will suffice:

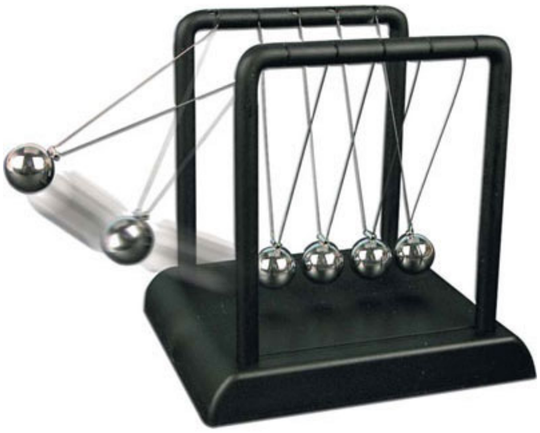


Figure 9.82: **Newton's cradle (pendulum)**

The operating principle is as follows:

If you throw a ball, at the end a single ball will move. That seems logical and coherent according to the conservation of momentum arising from the conservation of energy as we have already seen.

A little bit more curious (funny): when we initially launch two balls, two balls moves at the other end!

The proof is simple and the operation is based on a very simple condition that we are going to determine for the special case of two balls (it's always the same principle for a higher number of balls):

Given p_{1i}, p_{2i} the linear momentum of the two initial balls, and p_{1f}, p_{2f} those of the two ball at the other end, we have:

$$m_1v_{1i}+m_2v_{2i}=m_1v_{1f}+m_2v_{2f} \tag{9.3.779}$$

We then have for the kinetic energy:

$$\frac{1}{2}m_1v_{1i}^2+\frac{1}{2}m_2v_{2i}^2=\frac{1}{2}m_1v_{1f}^2+\frac{1}{2}m_2v_{2f}^2 \tag{9.3.780}$$

after consolidation and simplification of the two previous relations:

$$\begin{aligned}m_1(v_{1i}-v_{1f})&=m_2(v_{2f}-v_{2i})\\ m_1(v_{1i}^2-v_{1f}^2)&=m_2(v_{2f}^2-v_{2i}^2)\end{aligned} \tag{9.3.781}$$

From the second relation above we have:

$$m_1(v_{1i}-v_{1f})(v_{1i}+v_{1f})=m_2(v_{2f}-v_{2i})(v_{2f}+v_{2i}) \tag{9.3.782}$$

Dividing by the first it remains:

$$(v_{1i}+v_{1f})=(v_{2f}+v_{2i}) \tag{9.3.783}$$

We draw from that:

$$\begin{aligned}v_{1f}&=v_{2f}+v_{2i}-v_{1i}\\ v_{2f}&=v_{1i}+v_{1f}-v_{2i}\end{aligned} \tag{9.3.784}$$

Let us inject the first of these two relations in:

$$m_1(v_{1i}+v_{1f})=m_2(v_{2f}+v_{2i}) \tag{9.3.785}$$

Then we have:

$$m_1(v_{1i}-(v_{2f}+v_{2i}-v_{1i}))=m_2(v_{2f}-v_{2i}) \tag{9.3.786}$$

This gives us after rearranging:

$$v_{2f}=\frac{v_{2i}(m_2-m_1)+2m_1v_{1i}}{m_1+m_2} \tag{9.3.787}$$

At the end by doing the same for the other final speed, we deduce the expression of the two speeds after the elastic collision:

$$\boxed{v_{1f}=\frac{v_{1i}(m_1-m_2)+2m_2v_{2i}}{m_1+m_2}\qquad v_{2f}=\frac{v_{2i}(m_2-m_1)+2m_1v_{1i}}{m_1+m_2}} \tag{9.3.788}$$

Hypothesis: Suppose now that by taking one of the balls with $v_{2i}=0$ there are two who go away at the other such as:

$$v_{1f}=\frac{v_{1i}(m_1-m_2)}{m_1+m_2}\qquad v_{2f}=\frac{2m_1v_{1i}}{m_1+m_2} \tag{9.3.789}$$

and in the latter situation consider the case where all of Newton pendulum balls have the same mass (cases corresponding to that we can find in science shops). So:

$$m_1=m_2\Rightarrow v_{1f}=0, v_{2f}=v_{1i} \tag{9.3.790}$$

We see that our initial assumption is false: if with equal masses, a single ball is launched then, at the other end, only one ball will leave by conservation of momentum (assuming the "elastic collisions")!

By cons, if we launch two balls in a Newton's cradle composed of identical masses we have after simplification of equations:

$$v_{1f}=v_{2i}\qquad v_{2f}=v_{1i} \tag{9.3.791}$$

two balls which leave at the other end.

We just need make the make similar development for $3,4,5,\ldots$ balls.

9.3.10.2 Simple Pendulum (mass-wire pendulum)

In physics, the "simple pendulum" is a point mass attached to the end of a massless wire attached to a friction-less pivot, inextensible and oscillating freely under the effect of uniform gravity. When a pendulum is displaced sideways from its resting, equilibrium position, it is subject to a restoring force due to gravity that will accelerate it back toward the equilibrium position. When released, the restoring force combined with the pendulum's mass causes it to oscillate about the equilibrium position, swinging back and forth.

This is the simplest model of "weighted pendulum". It is sometimes named "ideal gravity pendulum" when we consider the experience in vacuum.

Remark

From the first scientific investigations of the pendulum around 11602 (holocene calendar) by Galileo Galilei, the regular motion of pendulums was used for timekeeping, and was the world's most accurate timekeeping technology until the 11930s (holocene calendar). The pendulum clock invented by Christian Huygens in 11658 (holocene calendar) became the world's standard timekeeper, used in homes and offices for 270 years, and achieved accuracy of about one second per year before it was superseded as a time standard by quartz clocks in the 11930s (holocene calendar). Pendulums are also used in scientific instruments such as accelerometers and seismometers. Historically they were used as gravimeters to measure the acceleration of gravity in geophysical surveys, and even as a standard of length.

Either T the period of time required for a simple pendulum (see figure below) goes through a complete cycle and that we can write:

$$T=\frac{2\pi}{\omega} \tag{9.3.792}$$

which is the inverse of the "natural frequency" f of the system in the absence of friction.

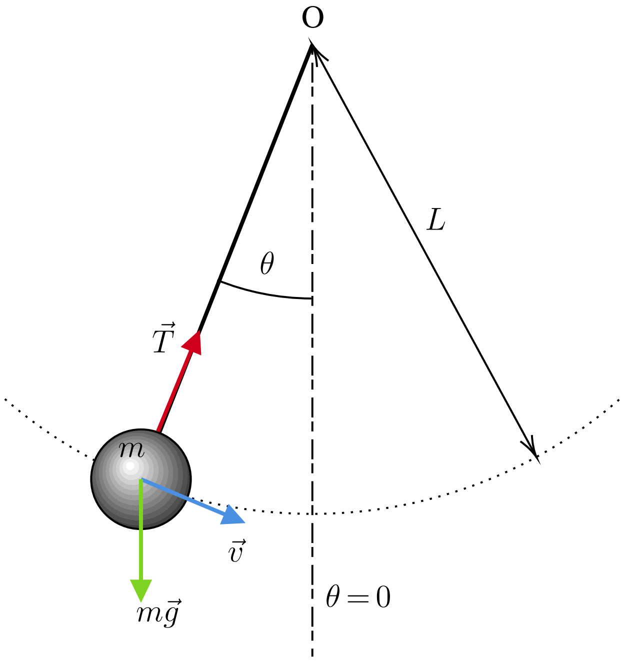

Figure 9.83: **Schematic ideal simple pendulum**

Given L the length of the pendulum rod/wire, and either:

$$\omega=\dot{\theta}=\frac{\mathrm{d}\theta}{\mathrm{d}t} \tag{9.3.793}$$

its angular velocity. The velocity of the mass (massive bob) is then:

$$v=\omega L=\dot{\theta}L \tag{9.3.794}$$

The sum of the kinetic energy of the pendulum and its gravitational potential energy, measured from the pendulum suspension point (so that when $\theta=0$ the potential energy is zero), is in the case without friction and if the pendulum is not forced:

$$E_{\text{tot}}=E_c+E_p=\frac{1}{2}mL^2\dot{\theta}^2+mgL(1-\cos(\theta)) \tag{9.3.795}$$

So the total energy being constant by assumption, its derivative with respect to time is zero. Then we have:

$$\frac{\mathrm{d}E_{\text{tot}}}{\mathrm{d}t}=mL^2\dot{\theta}\frac{\mathrm{d}\dot{\theta}}{\mathrm{d}t}+mgL\sin(\theta)\frac{\mathrm{d}\theta}{\mathrm{d}t}=mL^2\dot{\theta}\ddot{\theta}+mgL\dot{\theta}\sin(\theta)=0 \tag{9.3.796}$$

Then we divide by $mL^2\dot{\theta}$ which excludes the solution when the massive pop is stopped. Then we have:

$$\ddot{\theta}+\frac{g}{L}\sin(\theta)=0 \tag{9.3.797}$$

and from the perspective of the units, it is customary to note this in the form of a non-linear second order differential equation of the second of the type:

$$\boxed{\ddot{\theta}+\omega_0^2+\omega_0^2\sin(\theta)=0} \tag{9.3.798}$$

with therefore:

$$\omega_0=\sqrt{\frac{g}{L}} \tag{9.3.799}$$

Who has a physical interpretation in the sense that when $\theta=\pi/2$, we have:

$$\ddot{\theta}+\omega_0^2\sin\left(\frac{\pi}{2}\right)=0\Rightarrow\ddot{\theta}+\omega_0^2=0\Rightarrow\ddot{\theta}=-\omega_0^2 \tag{9.3.800}$$

That is why ω_0 is considered as the initial pulse.

Remark

If the initial pulse depends of the time, the problem is taken down to what is named an "adiabatic pendulum".

For small oscillations, we know that by Taylor expansion of the sine (see section Sequences and Series page 1703), the differential equation can be written:

$$\ddot{\theta}+\omega_0^2\theta=0 \tag{9.3.801}$$

Which has a trivial solution:

$$\theta(t)=\theta_0\cos(\omega_0 t) \tag{9.3.802}$$

And we also deduce from it the frequency and thus the oscillation period:

$$\omega_0=2\pi f\Leftrightarrow T=2\pi\sqrt{\frac{L}{g}} \tag{9.3.803}$$

So we get the famous relation (don't forget it is an approximation!):

$$\boxed{T\cong 2\pi\sqrt{\frac{L}{g}}} \tag{9.3.804}$$

So the swing period is independent of the amplitude if the latter is small, which explains why the number of swings per minute of a simple pendulum is constant, whatever the force we put to the swinging ... We talk then of "isochronism"!

If:

$$L=l_0+NP \tag{9.3.805}$$

where l_0 is the position of the center of mass of the object and N the number of potential links of the chain (rather than a wire) that we would have taken for the length L of the chain and P is the pitch of the chain.

Which finally gives obviously:

$$T \cong \frac{2\pi}{\omega_0}\sqrt{\frac{l_0+NP}{g}} \tag{9.3.806}$$

Notice that our differential equation can also be reduced to a differential system of equations of the first order (transformation useful for many computer softwares such as Maple™ and MATLAB® for example as they request such an input!):

$$\frac{\mathrm{d}^2\theta}{\mathrm{d}t} = -\omega_0^2\sin(\theta) \underset{\substack{x=\theta \\ y=\mathrm{d}x/\mathrm{d}t}}{\Leftrightarrow} \frac{\mathrm{d}}{\mathrm{d}t}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} y \\ -\omega_0^2\sin(x) \end{bmatrix} \tag{9.3.807}$$

With Maple™ 4.00b we can plot thanks to this above relation the phase diagram $\theta-\omega$:

```
>with(DEtools):
>omega:=2:
>phaseportrait([diff(x(t),t)=y(t),diff(y(t),t)=-omega*sin(x(t))],
[x(t),y(t)],t=-10..20,[[x(0)=-2,y(0)=0],[x(0)=3,y(0)=0],[x(0)=1,y(0)=4]],
x=-4..7,y=-7..7,stepsize=0.1,linecolour=[blue,violet,green]);
```

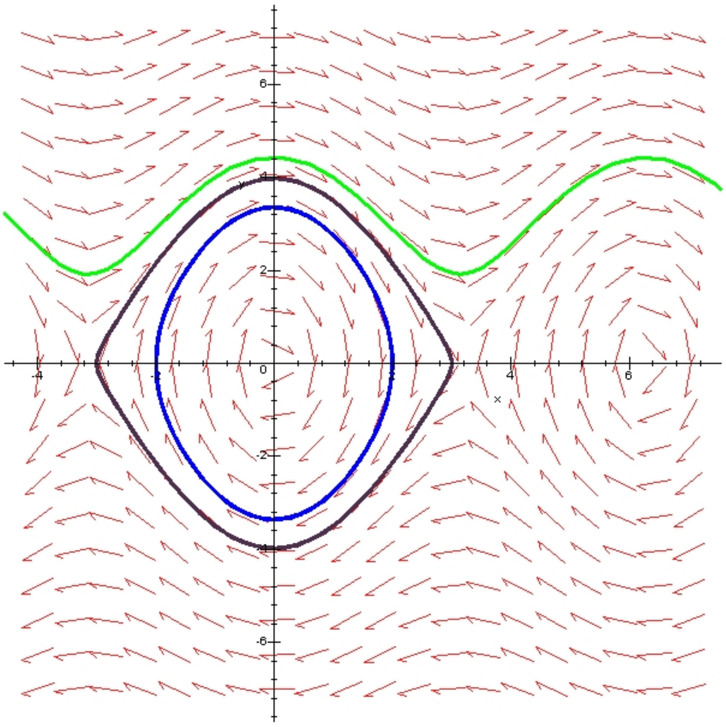

Figure 9.84: **Phase space $\theta-\omega$ of the simple pendulum in Maple™ 4.00b**

We must then know how to read this result:

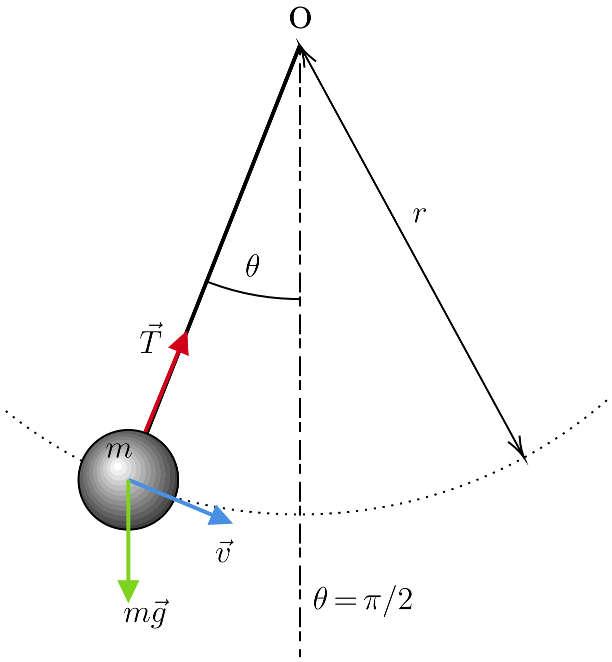
1. If the starting angle `x(0)` is small or large and the starting pulsation `y(0)` is small, the angle remains bounded and the pendulum then has a finite (non-revolving) balanced movement (blue and violet on the plot)

2. Whether the starting angle `x(0)` is small or large if the launching speed `y(0)` is positive and greater than a certain critical value, then the pendulum has an infinite revolving movement (green on the plot)

For the people interested in the Lagrangian approach of the simple ideal pendulum we start as always with the Euler-Lagrange equation (see section Analytical Mechanics page 3162):

$$L=T-V=\frac{1}{2}m(\dot{r}^2+r^2\dot{\theta})+mgr\cos(\theta) \tag{9.3.808}$$

Taking the potential V to be zero when the pendulum is horizontal $\theta=\pi/2$ and expressing the speed in polar coordinates (see section Vector Calculus page 1863).



Now we use our equation of motion:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{\theta}}\right)-\frac{\partial L}{\partial\theta}=0 \tag{9.3.809}$$

This gives us:

$$\frac{\mathrm{d}}{\mathrm{d}t}(mr^2\dot{\theta})+mgr\sin(\theta)=0 \tag{9.3.810}$$

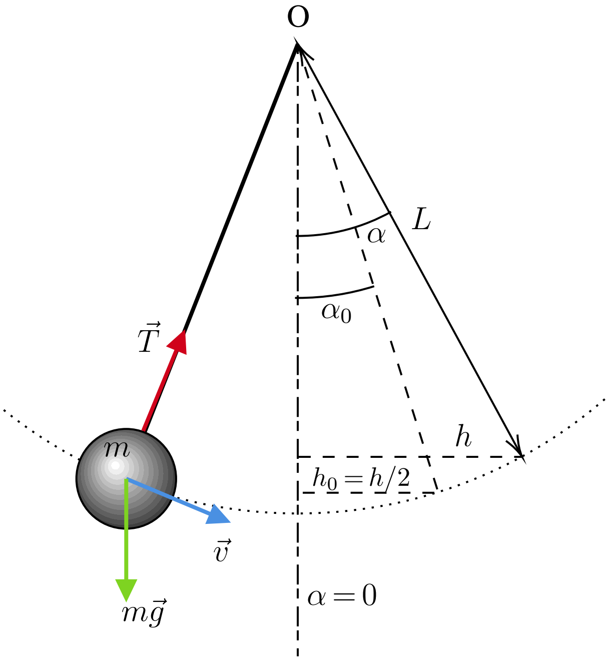
Therefore:

$$mr^2\ddot{\theta}+mgr\sin(\theta)=0 \tag{9.3.811}$$

and we fall back on our ODE...

Finally to close this subject on the simple pendulum, some textbooks (especially computer science textbooks????) give another approach based on the fact that the final relation must be given using an Elliptic Integral (it's a matter of choice). For this purpose let us rewrite the total energy at the angle α_0 where the kinetic energy is equal to the potential energy (obviously the α_0 is where the potential energy is equal to the kinetic energy is a the half height):

$$\frac{1}{2}mL^2\dot{\alpha}^2=mgL(\cos(\alpha_0)-\cos(\alpha)) \tag{9.3.812}$$



That can be rewritten as:

$$(\mathrm{d}t)^2=\frac{L(\mathrm{d}\alpha)^2}{2g(\cos(\alpha)-\cos(\alpha_0))} \tag{9.3.813}$$

therefore:

$$\mathrm{d}t=\sqrt{\frac{L}{2g}}\frac{\mathrm{d}\alpha}{\sqrt{\cos(\alpha)-\cos(\alpha_0)}} \tag{9.3.814}$$

Now if we integrate from $\alpha=0\ldots\alpha_0$, as we need four times this angle to make a complete cycle (indeed! remember that we were are the half height!), we then have:

$$T=4\sqrt{\frac{L}{2g}}\int\limits_0^{\alpha_0}\frac{\mathrm{d}\alpha}{\sqrt{\cos(\alpha)-\cos(\alpha_0)}} \tag{9.3.815}$$

Now let us use some trigonometric identities (see section Trigonometry page 2519):

$$\begin{gathered}\cos(\alpha)=1-2\sin^2\left(\frac{\alpha}{2}\right)\\ \cos(\alpha_0)=1-2\sin^2\left(\frac{\alpha_0}{2}\right)\end{gathered} \tag{9.3.816}$$

By putting:

$$p=\sin\left(\frac{\alpha_0}{2}\right) \tag{9.3.817}$$

Then we have:

$$T=\sqrt{\frac{L}{2g}}\int\limits_0^{\alpha_0}\frac{\mathrm{d}\alpha}{\cos(\alpha)-\cos(\alpha_0)}=2\sqrt{\frac{L}{g}}\int\limits_0^{\alpha_0}\frac{\mathrm{d}\alpha}{p^2-\sin^2\left(\frac{\alpha}{2}\right)} \tag{9.3.818}$$

We now carry out a series of subtle transformations beginning with a change of variable:

$$\sin\left(\frac{\alpha}{2}\right)=p\sin(\theta)=\sin\left(\frac{\alpha_0}{2}\right)\sin(\theta) \tag{9.3.819}$$

So when:

$$\alpha=0\Rightarrow\theta=0 \tag{9.3.820}$$

and:

$$\alpha=\alpha_0\Rightarrow\theta=\frac{\pi}{2} \tag{9.3.821}$$

In addition:

$$\begin{aligned}&\mathrm{d}\left(\sin\left(\frac{\alpha}{2}\right)\right)=\frac{1}{2}\cos\left(\frac{\alpha}{2}\right)\mathrm{d}\alpha\\&\mathrm{d}(p\sin(\theta))=p\cos(\theta)\mathrm{d}\theta\end{aligned} \tag{9.3.822}$$

It follows, since we have put for recall that:

$$\sin\left(\frac{\alpha}{2}\right)=p\sin(\theta) \tag{9.3.823}$$

that we then have:

$$\frac{1}{2}\cos\left(\frac{\alpha}{2}\right)\mathrm{d}\alpha=p\cos(\theta)\mathrm{d}\theta \tag{9.3.824}$$

and therefore:

$$\begin{aligned}\mathrm{d}\alpha&=\frac{2p\cos(\theta)}{\cos\left(\frac{\alpha}{2}\right)}\mathrm{d}\theta=\frac{2p\sqrt{1-\sin^2(\theta)}}{\sqrt{1-\sin^2\left(\frac{\alpha}{2}\right)}}\mathrm{d}\theta=\frac{2\sqrt{p^2-p^2\sin^2(\theta)}}{\sqrt{1-\sin^2\left(\frac{\alpha}{2}\right)}}\mathrm{d}\theta\\&=\frac{2\sqrt{p^2-\sin^2\left(\frac{\alpha}{2}\right)}}{\sqrt{1-\sin^2\left(\frac{\alpha}{2}\right)}}\mathrm{d}\theta=\frac{2\sqrt{p^2-\sin^2\left(\frac{\alpha}{2}\right)}}{\sqrt{1-p^2\sin^2(\theta)}}\mathrm{d}\theta\end{aligned} \tag{9.3.825}$$

Then we have:

$$T=2\sqrt{\frac{L}{g}}\int\limits_0^{\alpha_0}\frac{\mathrm{d}\alpha}{\sqrt{p^2-\sin^2\left(\frac{\alpha}{2}\right)}}=2\sqrt{\frac{L}{g}}\int\limits_0^{\pi/2}\frac{\frac{2\sqrt{p^2-\sin^2\left(\frac{\alpha}{2}\right)}}{\sqrt{1-p^2\sin^2(\theta)}}}{\sqrt{p^2-\sin^2\left(\frac{\alpha}{2}\right)}}\mathrm{d}\theta=4\sqrt{\frac{L}{g}}\int\limits_0^{\pi/2}\frac{\mathrm{d}\theta}{\sqrt{1-p^2\sin^2(\theta)}} \tag{9.3.826}$$

Either in the condensed form of the "elliptic integral of the first kind" (see section Differential and Integral Calculus page 1599):

$$\boxed{T=4\sqrt{\frac{L}{g}}\int\limits_0^{\pi/2}\frac{\mathrm{d}\theta}{\sqrt{1-p^2\sin^2(\theta)}}=4\sqrt{\frac{L}{g}}F\left(\frac{\pi}{2},p^2\right)} \tag{9.3.827}$$

We notice first that if in the integral $p=0$ we fall back on the relation we get earlier:

$$T=2\pi\sqrt{\frac{L}{g}} \tag{9.3.828}$$

We speak then of the "harmonic limit" (small initial angle amplitude).

We can make an approximation of $F(\pi/2,p^2)$ at the neighbourhood of $p=0$. For this we use the Taylor development (see section Sequences and Series page 1703):

$$\frac{1}{\sqrt{1-x^2\sin(\theta)}}=1+\frac{\sin^2(\theta)}{2}p^2+\mathcal{O}(x^4\sin^4(\theta)) \tag{9.3.829}$$

Then we can approach the integral for small x:

$$F\left(\frac{\pi}{2},p^2\right)\cong\int\limits_0^{\pi/2}\left(1+\frac{\sin^2(\theta)}{2}p^2+\mathcal{O}(p^4\sin^4(\theta)\right)\mathrm{d}\theta=\frac{\pi}{2}\left(1+\frac{1}{4}p^2+\mathcal{O}(p^4)\right) \tag{9.3.830}$$

Which gives:

$$F\left(\frac{\pi}{2},p^2\right)\cong4\sqrt{\frac{L}{g}}\frac{\pi}{2}\left(1+\frac{1}{4}p^2+\mathcal{O}(p^4)\right)=2\pi\sqrt{\frac{L}{g}}\left[1+\frac{1}{4}\sin^2\left(\frac{\alpha_0}{2}\right)+\mathcal{O}\left(\sin^2\left(\frac{\alpha_0}{2}\right)\right)\right] \tag{9.3.831}$$

Finally, if we neglect the terms of order 4, we have $\sin^2(\alpha_0/2)\cong\alpha_0^2/2$ and then we get finally the "Borda approximation":

$$T\cong2\pi\sqrt{\frac{L}{g}}\left(1+\frac{\alpha_0^2}{16}\right) \tag{9.3.832}$$

The dependence of the period with the amplitude of the oscillations is therefore quadratic. This an anharmonic effect due to the non-parabolic profile of the potential well in which is trapped the pendulum. However, the Borda formula produces an error greater than 1% as soon as α_0 exceeds $74°$.

There is - and this is less known - an approximate formula based on the arithmetico-geometric mean, which by far exceeds the performance of most of the other formulas found in the literature.

9.3.10.3 Physical Pendulum

We name "physical pendulum" any solid that can oscillate freely in gravity and in vacuum around a friction-less axis A, with a small amplitude ($|\theta_0| < 5°$):

First remember that we have proved during our study of inertia momentum that:

$$\vec{M} = J\frac{\mathrm{d}\vec{\omega}}{\mathrm{d}t} \tag{9.3.833}$$

What we will write here in scalar form as:

$$M = J_A\frac{\mathrm{d}\omega}{\mathrm{d}t} = J_A\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2} \tag{9.3.834}$$

where for recall M is the force momentum (torque) that take back the pendulum to its equilibrium position and J_a the moment of inertia of the pendulum from its support axis A.

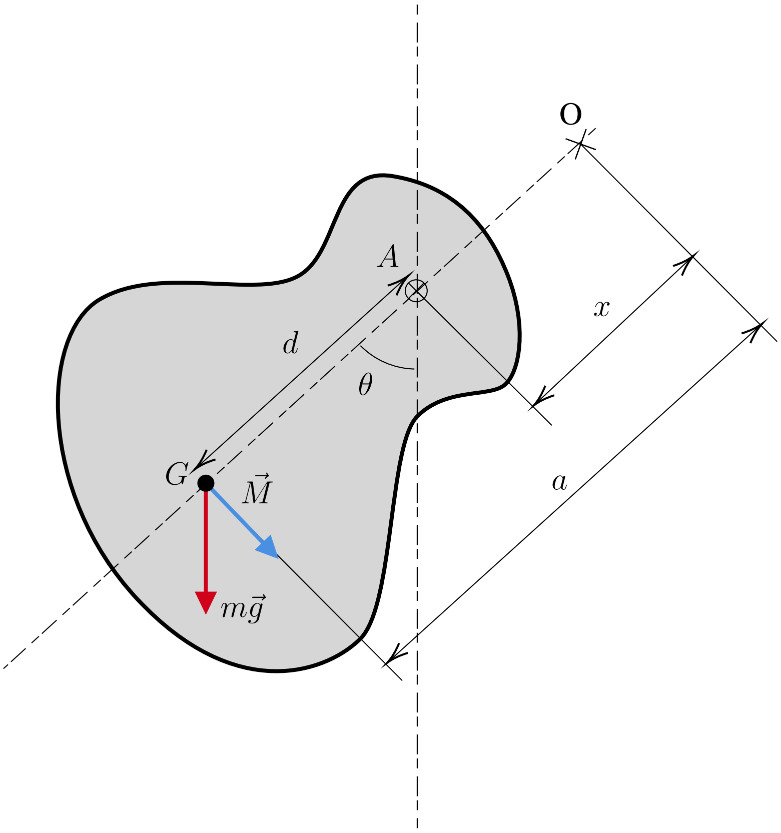


Figure 9.85: **Schematic ideal physical pendulum**

By analysing the force of our pendulum relatively to its centroid G we get another relation for M:

$$M = -Fd = -mg\cos\left(\frac{\pi}{2}-\theta\right)d = -mg\sin(\theta)d \cong -mgd\theta \tag{9.3.835}$$

For $\theta - 0 \leq \theta \leq \theta_0$ and where d is the distance from the friction-less axis of support of the pendulum to its center of mass G. The negative term appears here to express the fact that the period decreases with time (because the torque opposes the angular displacement from equilibrium).

As the angles θ are small, we replaced $\sin(\theta)$ without not too serious error by the first term of its development in Taylor series as for the simple pendulum (see section Sequences and Series page 1696).

Therefore we can write:

$$M=J_A\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}\cong -mgd\theta \tag{9.3.836}$$

Hence the following differential equation of movement:

$$J_A\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}+mgd\theta=0\Leftrightarrow\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}+\frac{mgd}{J_A}\theta=0 \tag{9.3.837}$$

Or in a more condensed way:

$$\ddot{\theta}+\omega_0\theta=0 \tag{9.3.838}$$

So we have exactly the same type of differential equation as the simple pendulum for which a trivial solution is:

$$\theta(t)=\theta_0\cos(\omega_0 t) \tag{9.3.839}$$

but now with:

$$\omega_0=\sqrt{\frac{mgd}{J_A}} \tag{9.3.840}$$

Hence:

$$\boxed{T=2\pi\sqrt{\frac{J_A}{mgd}}} \tag{9.3.841}$$

✍**Example:**

Let us calculate the oscillation period of a swinging rod pivoting about one of its end. As we proved in the section of Geometry, for such a shape we have (see page 2926):

$$I=\frac{ML^2}{3} \tag{9.3.842}$$

Then:

$$T=2\pi\sqrt{\frac{\dfrac{ML^2}{3}}{Mg(L/2)}}=2\pi\sqrt{\frac{2L}{3g}} \tag{9.3.843}$$

Expressing the moment of inertia J_A using Steiner's theorem proven earlier during our study of inertial momentum :

$$J_A=J_G+md^2 \tag{9.3.844}$$

and further introducing the radius of gyration k:

$$J_A = mk^2 + md^2 \tag{9.3.845}$$

Hence:

$$J_A = md\left(\frac{k^2}{d} + d\right) \tag{9.3.846}$$

Given x the position of the axis of rotation A measured relatively to any one origin and a the position of center of gravity G with respect to the same origin we have:

$$d = |x - a| \tag{9.3.847}$$

as visible in the figure above. Therefore:

$$J_A = m|x-a|\left(\frac{k^2}{|x-a|} + |x-a|\right) \tag{9.3.848}$$

which gives us then another well known form of the period of the physical pendulum:

$$\boxed{T = 2\pi\sqrt{\frac{1}{g}\left(\frac{k^2}{|x-a|} + |x-a|\right)}} \tag{9.3.849}$$

As the root square is not comfortable we rise the whole at the square, which ultimately gives us:

$$T^2 = \frac{4\pi^2}{g}\left(\frac{k^2}{|x-a|} + |x-a|\right) \tag{9.3.850}$$

As we know x and T, this relation will allow us to draw a graph to determine the position of G and k if needed.

Thus, by plotting T^2 in function of x:

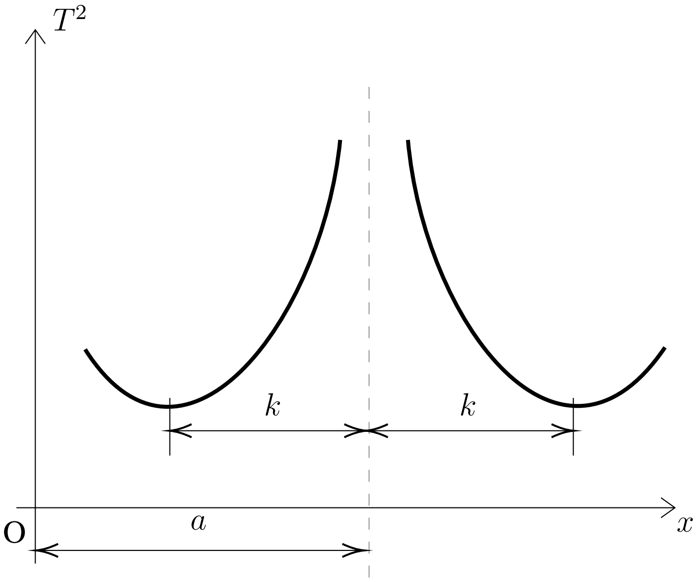

Figure 9.86: **Illustration of the vertical asymptote for determining the center of mass**

The resulting curve has a vertical asymptote ($T = +\infty$) for $x = a$ and two minima.

Differentiating T^2 with respect to x and cancelling the derivatives, we find the position of the minima:

$$x = a \pm k \tag{9.3.851}$$

9.3.10.4 Elastic Pendulum (mass-spring pendulum)

A "spring pendulum" (also named "elastic pendulum" or swinging spring) is a physical system where a piece of mass is connected to a spring so that the resulting motion contains elements of a simple pendulum as well as a spring. The system is much more complex than a simple pendulum, as the properties of the spring add an extra dimension of freedom to the system. For example, when the spring compresses, the shorter radius causes the spring to move faster due to the conservation of angular momentum. It is also possible that the spring has a range that is overtaken by the motion of the pendulum, making it practically neutral to the motion of the pendulum.

9.3.10.4.1 One degree of freedom elastic pendulum with/without friction

First let us consider the natural oscillations of a solid suspended in an elastic spring as it oscillates. After the separation of the solid from the equilibrium position, it will perform harmonic oscillations in the vertical direction, under the assumption that the elastic spring undergoes deformations proportional to the elongation (tension) of the spring.

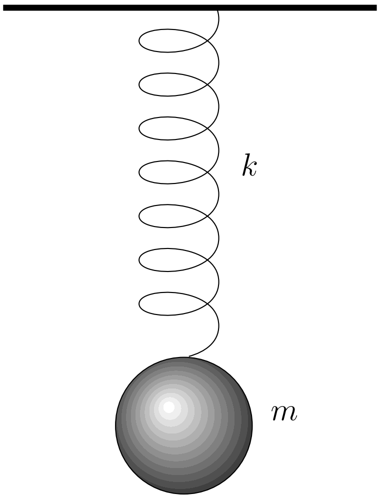

Figure 9.87: **Schematic ideal physical one degree of freedom pendulum**

We will often have to make in this textbook small movements around an equilibrium position.

This type of movement characteristic of what we name a "harmonic oscillator" is very common. It generalizes to all kinds of physical situations, such as RLC circuits (see section Electrical Engineering page 8475), the particle and wave quantum model of the atom (see section Wave Quantum Physics page 4688), quartz resonators or other vibrating structure slightly around its equilibrium point (see section Molecular Chemistry page 6211).

Remark

The harmonic oscillator is important because it's an approximate solution to nearly every system with a minimum of potential energy!

The reasoning comes from Taylor expansion (see section Sequences and Series page 1696). Consider a system with potential energy given by $U(x)$. You can approximate U at $x=x_0$ by:

$$U(x)=U(x_0)+(x-x_0)\left.\frac{\mathrm{d}U}{\mathrm{d}x}\right|_{x_0}+\frac{(x-x_0)^2}{2!}\left.\frac{\mathrm{d}^2U}{\mathrm{d}x^2}\right|_{x_0}+\ldots \tag{9.3.852}$$

The system will tend to settle into the configuration where $U(x)$ has a minimum - but, by definition, that's where the first derivative $\mathrm{d}U/\mathrm{d}x=0$ vanishes. Also a constant offset to a potential energy usually does not affect the physics. That leaves us with:

$$U(x)=\frac{(x-x_0)^2}{2!}\left.\frac{\mathrm{d}^2U}{\mathrm{d}x^2}\right|_{x_0}+\mathcal{O}(x-x_0)^3\cong\frac{1}{2}k(x-x_0)^2 \tag{9.3.853}$$

which is the harmonic oscillator potential for small oscillations around x_0.

We know that the restoring force (Hooke's law) of a spring is proportional and opposite to the strain such that (see section Continuum Mechanics page 3416):

$$F=ma=-k\Delta L \tag{9.3.854}$$

The differential equation of the harmonic oscillator can then be written:

$$\frac{\mathrm{d}^2x}{\mathrm{d}t^2}=-\frac{k}{m}x \tag{9.3.855}$$

We will take the simple approach that to try a solution, intuitively of the type... (exactly the same type as for the Simple Pendulum and Physical Pendulum):

$$x(t)=\cos(\omega_0 t) \tag{9.3.856}$$

It is a solution, because indeed:

$$\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}t}&=-\omega_0\sin(\omega t)\\ \frac{\mathrm{d}^2x}{\mathrm{d}t^2}&=-\omega_0^2\cos(\omega t)\end{aligned} \tag{9.3.857}$$

provided that we take the natural frequency:

$$\omega_0=\sqrt{\frac{k}{m}} \tag{9.3.858}$$

So we get the famous period relation for the elastic pendulum:

$$\boxed{T=2\pi\sqrt{\frac{m}{k}}} \tag{9.3.859}$$

We also have the "proper mode":

$$x(t)=\sin(\omega_0 t) \tag{9.3.860}$$

as a solution.

A general solution is as we know (see section Differential and Integral Calculus page 1609):

$$x(t)=A\sin(\omega_0 t)+B\cos(\omega_0 t) \tag{9.3.861}$$

To find A and B, we must specify the initial conditions. Let us take for example at $t=0$:

$$x(0)=x_0=\Delta l \qquad v(0)=v_0 \tag{9.3.862}$$

Then we have:

$$\begin{aligned}x(t=0)&=B=\Delta l\\ v(t)&=A\omega\cos(\omega t)-B\sin(\omega t)\\ v(0)&=A\omega=v_0\end{aligned} \tag{9.3.863}$$

Let us now calculate the work (energy) needed to deform the harmonic oscillator. We have:

$$W=\int_{x_1}^{x_2}F\mathrm{d}x=\int_{x_1}^{x_2}kx\mathrm{d}x=k\int_{x_1}^{x_2}x\mathrm{d}x=\frac{1}{2}k(x_2^2-x_1^2)=\frac{1}{2}k\Delta x^2 \tag{9.3.864}$$

Thus, the elastic potential energy in a spring of material constant k, which have undergone a deformation x from it's initial position is thus given by:

$$\boxed{E_{\text{elastic}}=\frac{1}{2}kx^2} \tag{9.3.865}$$

For a more realistic description, a better modelling, we assume that the oscillator is subjected to an additional force representing friction. Often the approximation in which the friction force is proportional to the speed, and opposite to the speed, is a good approximation. It is not the only possible one and it is not always the best. We'll talk about friction forces (tribology) later.

Thus we consider a frictional force of the form (not to be confused with the notation of the momentum $\vec{b}$ that has absolutely no relation):

$$\vec{F}_f=-b\vec{v} \tag{9.3.866}$$

For our coordinate system:

$$F_f=-b\frac{\mathrm{d}x}{\mathrm{d}t} \tag{9.3.867}$$

The Newton's second law imposes:

$$m\frac{\mathrm{d}^2x}{\mathrm{d}t^2}=-kx-b\frac{\mathrm{d}x}{\mathrm{d}t} \tag{9.3.868}$$

Frequently written in the following important form:

$$\boxed{\frac{\mathrm{d}^2x}{\mathrm{d}t^2}+b\frac{\mathrm{d}x}{\mathrm{d}t}+kx=0} \tag{9.3.869}$$

Remark

For the forced version of this differential equation, introducing the concept of "resonance", the reader should refer to the page 8224.

To comply with a standard notation as part of the oscillator's study, we write:

$$\frac{k}{m}=\omega_0^2 \qquad \frac{b}{2m}=\gamma \tag{9.3.870}$$

hence the differential equation:

$$\frac{\mathrm{d}^2x}{\mathrm{d}t^2}+2\gamma\frac{\mathrm{d}x}{\mathrm{d}t}+\omega_0^2x=0 \tag{9.3.871}$$

We take the trail function:

$$x=e^{\lambda t} \tag{9.3.872}$$

Substituting, we find:

$$e^{\lambda t}\left(\lambda^2+2\gamma\lambda+\omega_0^2\right)=0 \tag{9.3.873}$$

As we seek non-zero solutions ($e^{\lambda t}$) we must have:

$$\lambda^2+2\gamma\lambda+\omega_0^2=0 \tag{9.3.874}$$

hence:

$$\begin{aligned}\lambda_1&=-\gamma+\sqrt{\gamma^2-\omega_0^2}\\ \lambda_2&=-\gamma-\sqrt{\gamma^2-\omega_0^2}\end{aligned} \tag{9.3.875}$$

and the general solution is:

$$x(t)=A_1e^{\lambda_1 t}+A_2e^{\lambda_2 t}=e^{-\gamma t}\left(A_1e^{\sqrt{\gamma^2-\omega_0^2}t}+A_2e^{-\sqrt{\gamma^2-\omega_0^2}t}\right) \tag{9.3.876}$$

where the two constants are determined by the initial conditions.

We will see that they corresponds to a low damping. Indeed, we can write with real square roots:

$$\lambda_{1,2}=-\gamma\pm\sqrt{\gamma^2-\omega_0^2}=-\gamma\pm\mathrm{i}\sqrt{\omega_0^2-\gamma^2} \tag{9.3.877}$$

the general solution can then be written as:

$$x(t)=e^{-\gamma t}\left(A_1e^{\mathrm{i}\sqrt{\omega_0^2-\gamma^2}t}+A_2e^{-\mathrm{i}\sqrt{\omega_0^2-\gamma^2}t}\right) \tag{9.3.878}$$

Using the complex (imaginary) properties of exponential and particularly the "Euler's formula" (see section Numbers page 251):

$$\begin{aligned}x(t)&=e^{-\gamma t}\left(A_1e^{\mathrm{i}\sqrt{\omega_0^2-\gamma^2}t}+A_2e^{-\mathrm{i}\sqrt{\omega_0^2-\gamma^2}t}\right)\\ &=e^{-\gamma t}\left(A_1\cos(\sqrt{\omega_0^2-\gamma^2}t)+\mathrm{i}A_1\sin(\sqrt{\omega_0^2-\gamma^2}t)+A_2\cos(-\sqrt{\omega_0^2-\gamma^2}t)+\mathrm{i}A_2\sin(-\sqrt{\omega_0^2-\gamma^2}t)\right)\end{aligned} \tag{9.3.879}$$

Let us choose $A_1 = A_2$ and recall that $\sin(-\alpha) = -\sin(\alpha)$ (see section Trigonometry page 2503). Therefore:

$$x(t) = e^{-\gamma t}\left(A_2\cos(\sqrt{\omega_0^2-\gamma^2}t) + A_2\cos(-\sqrt{\omega_0^2-\gamma^2}t)\right) \tag{9.3.880}$$

and as we also have $\cos(-\alpha) = \cos(\alpha)$. Then:

$$x(t) = e^{-\gamma t}2A_2\cos(\sqrt{\omega_0^2-\gamma^2}t) = e^{-\gamma t}C\cos(\sqrt{\omega_0^2-\gamma^2}t) \tag{9.3.881}$$

Let us put $\omega_1 = \sqrt{\omega_0^2-\gamma^2}$ and as the trigonometric function is periodic at $\phi = \pm 2k\pi$ with $k \in \mathbb{N}$ then:

$$x(t) = e^{-\gamma t}C\cos(\omega_1 t + \phi) \tag{9.3.882}$$

The general appearance of $x(t)$ for a given amplitude is a follows:

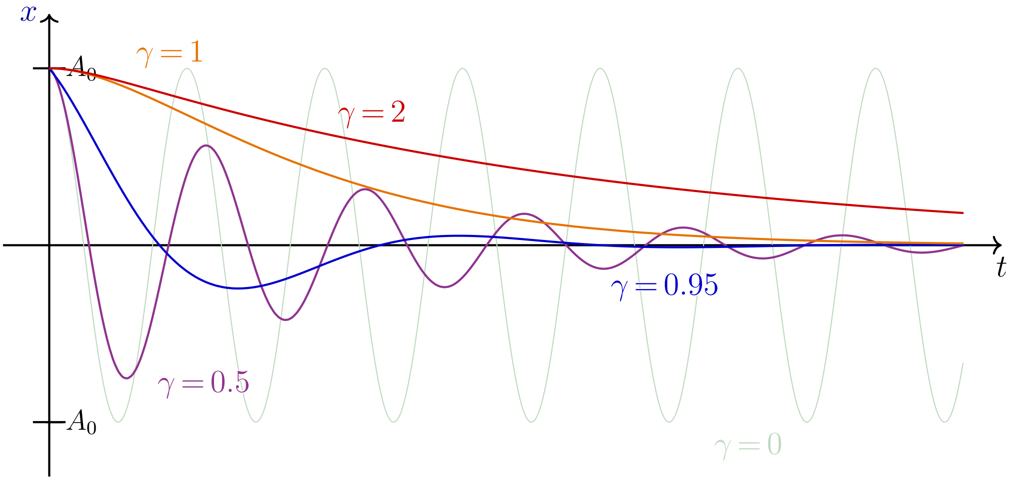

Figure 9.88: **Illustration of the amplitude damping of an elastic pendulum (author: Izaak Neutelings)**

And respectively for the energy:

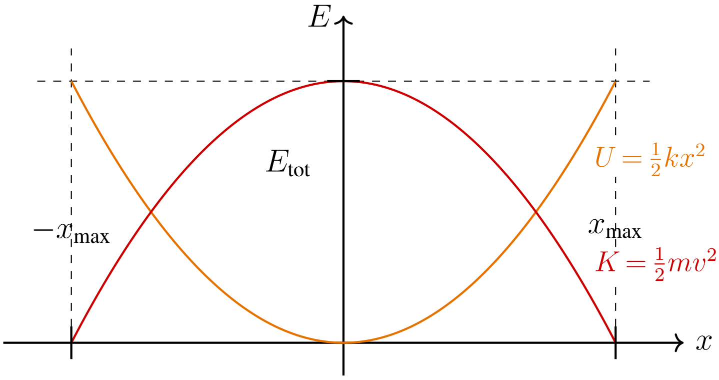

Figure 9.89: **Potential and Kinetic energy balancing of an elastic pendulum (author: Izaak Neutelings)**

When $\omega_0 = \gamma$ we say that there is a "critical damping", when $\omega_0 < \gamma$, we say that there is an "over-critical damping".

The dimensionless ratio:

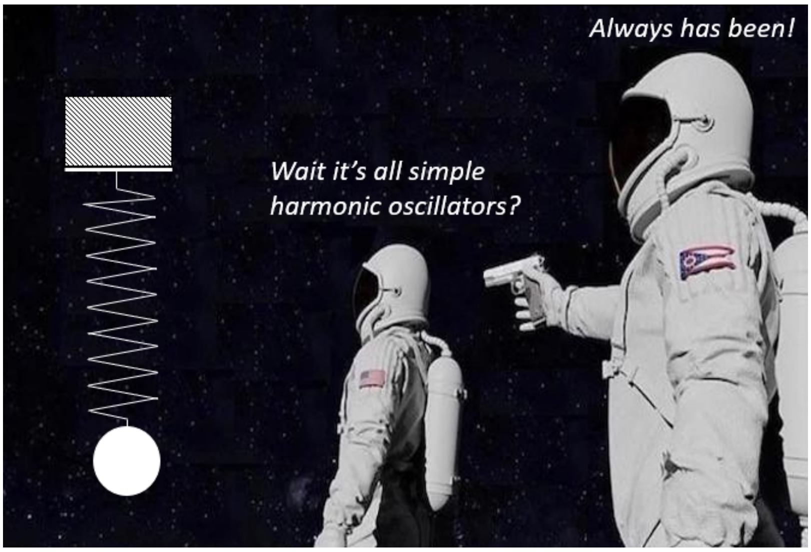
$$Q = \frac{\omega_0}{2\gamma} \tag{9.3.883}$$

meanwhile is named the "quality factor".

9.3.10.4.2 Harmonic oscillator (Lorentz oscillator)

The harmonic oscillator (also named "Lorentz oscillator") that is of main importance in many fields of physics is introduced in this textbook in the section of Music Mathematics at page 8224.

Once you will have finished to read that entire book you will very likely understand that meme:



Always has been!
Wait it's all simple
harmonic oscillators?

9.3.10.4.3 Two degrees of freedom elastic pendulum without friction

Now we consider an elastic pendulum that oscillates in the direction of the spring axes but that also oscillates in a $x - y$ plane:

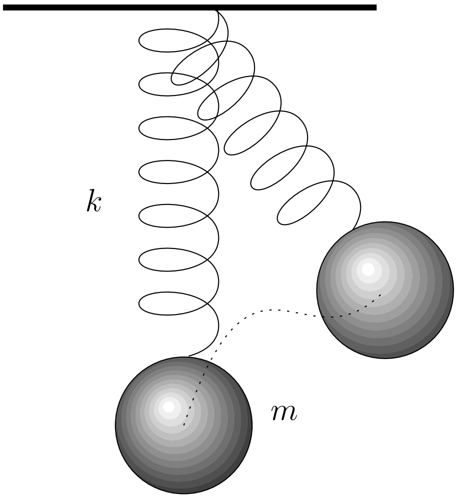


Figure 9.90: **Two degrees of freedom ideal elastic pendulum**

In practice the movement of such a pendulum seems chaotic but if we consider a friction-less pivot and that the experiment occurs in vacuum, it is still predictable!

Solving the equation of motion for such a pendulum cannot be done formally as far as we know and get the system of differential equation using the traditional method is quite awful.

So we will use the lagrangian approach. That is:

$$L = T - V \tag{9.3.884}$$

and:

$$\frac{\partial}{\partial t}\left(\frac{\partial L}{\partial \dot{q}}\right) - \frac{\partial L}{\partial q} \tag{9.3.885}$$

The kinetic energy may be broken up into the radial and tangential parts, so we have (the x component is along the axis of the spring relatively to the equilibrium length l_0 of the spring):

$$\begin{aligned}T &= T_{\text{rad}} + T_{\text{tan}} = \frac{1}{2}m\dot{x}^2 + \frac{1}{2}m(\omega r)^2 = \frac{1}{2}m\dot{x}^2 + \frac{1}{2}mr^2\omega^2 = \frac{1}{2}m\dot{x}^2 + \frac{1}{2}m(l_0+x)^2\dot{\theta}^2 \\ &= \frac{1}{2}m\left(\dot{x}^2 + (l_0+x)^2\dot{\theta}^2\right)\end{aligned} \tag{9.3.886}$$

The potential energy comes from both gravity and the spring, so we have:

$$V = E_p + E_{\text{elastic}} = -mg(l_0+x)\cos(\theta) + \frac{1}{2}kx^2 \tag{9.3.887}$$

The lagrangian is therefore:

$$L = T - V = \frac{1}{2}m\left(\dot{x}^2 + (l_0+x)^2\dot{\theta}^2\right) + mg(l_0+x)\cos(\theta) - \frac{1}{2}kx^2 \tag{9.3.888}$$

9.3.10.5 Conical Pendulum

A "conical pendulum", also sometimes named "circular pendulum",consists of a mass (or bob) fixed on the end of a string (or rod) suspended from a pivot. Its construction is similar to an ordinary pendulum; however, instead of swinging back and forth, the bob of a conical pendulum moves at a constant speed in a circle with the string (or rod) tracing out a cone.

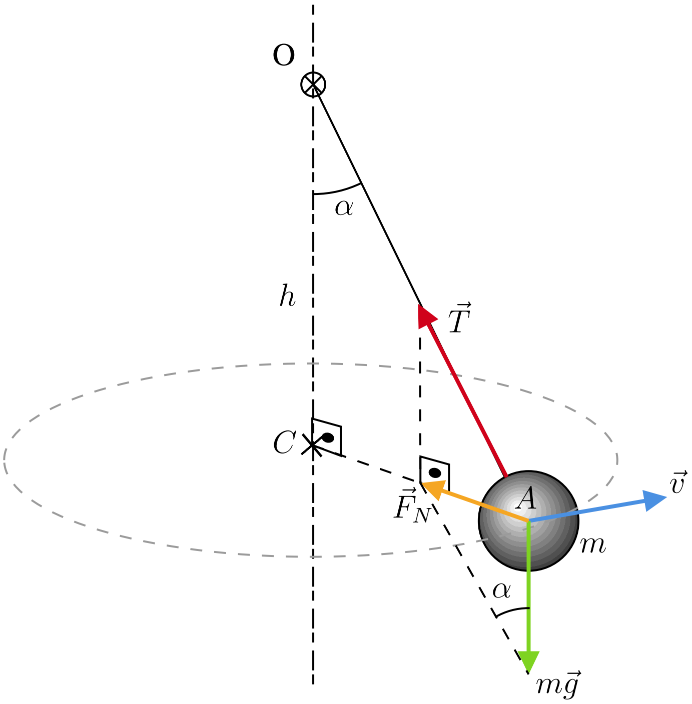

Figure 9.91: **Ideal conical pendulum**

As we can see above, the conical pendulum consist in taking a mass m considered as punctual and suspended to a rope of length $\overline{\text{O}A}=L$ to a friction-less pivot O.

The mass being taking to angle α of the vertical, the aim of this pendulum is frequently (because it is the simplest case) to determine the dependence between the angle and speed when you consider that trajectories are circular.

The mass m moves around the vertical $\overline{\text{O}C}$, describing a circle of radius:

$$r=\overline{CA}=\overline{\text{O}A}\sin(\alpha)=L\sin(\alpha) \tag{9.3.889}$$

The following forces act on the mass m:

$$\begin{aligned}F_g&=mg\\F_N&=m\frac{v^2}{R}=m\frac{(\omega R)^2}{R}=m\omega^2R=m\omega^2L\sin(\alpha)\end{aligned} \tag{9.3.890}$$

From the figure, we see that:

$$\tan(\alpha)=\frac{F_N}{F_G}=\frac{\omega^2L\sin(\alpha)}{g} \tag{9.3.891}$$

or, as:

$$\tan(\alpha)=\frac{\sin(\alpha)}{\cos(\alpha)} \tag{9.3.892}$$

then:

$$\cos(\alpha)=\frac{g}{\omega^2 L} \tag{9.3.893}$$

The angle α is even greater than the angular velocity ω is high, which is confirmed by the experience. For this reason, the conical pendulum was long used as cruise control on steam engines (it closes the steam supply when the speed exceeds a limit set in advance and opens when it falls below this value).

We have also:

$$\cos(\alpha)=\frac{g}{\left(\dfrac{v}{R}\right)^2 L}\Rightarrow v=\sqrt{\frac{R^2 g}{\cos(\alpha)L}}=\sqrt{\frac{g}{\cos(\alpha)L}}R=\sqrt{\frac{g}{\cos(\alpha)L}}L\sin(\alpha) \tag{9.3.894}$$

hence after simplification:

$$\boxed{v=\sqrt{\frac{gL}{\cos(\alpha)}}\sin(\alpha)} \tag{9.3.895}$$

As we have obviously $v=2\pi R/t$ (where t is the period to not confuse it with the T in the figure above that represents the tension) it comes:

$$T=2\pi R\sqrt{\frac{\cos(\alpha)L}{R^2 g}} \tag{9.3.896}$$

That is:

$$\boxed{t=2\pi\sqrt{\frac{\cos(\alpha)L}{g}}} \tag{9.3.897}$$

For small angles θ, $\cos(\theta)\cong 1$, and the period t of a conical pendulum is equal to the period of an ordinary pendulum of the same length. Also, the period for small angles is approximately independent of changes in the angle θ. This means the period of rotation is approximately independent of the force applied to keep it rotating. This property, named "isochronism", is shared with ordinary pendulums and makes both types of pendulums useful for timekeeping.

9.3.10.6 Torsion Pendulum

Consider a disk suspended from a torsion wire attached to its center (see figure below). This setup is known as a "torsion pendulum". A torsion wire is essentially inextensible, but is free to twist about its axis. Of course, as the wire twists it also causes the disk attached to it to rotate in the horizontal plane. Let θ be the angle of rotation of the disk, and let $\theta = 0$ correspond to the case in which the wire is untwisted.

Remark

The torsion pendulum is also a system that was used by Charles-Augustin Coulomb for measuring the elementary charge q_e and Henry Cavendish for measuring the gravitational constant G (see page 5270).

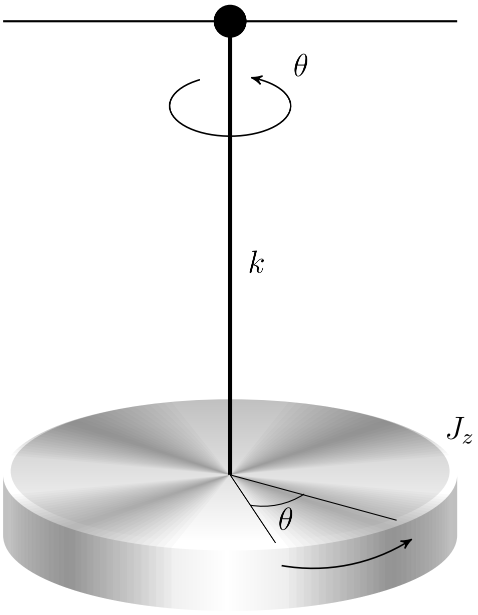

Figure 9.92: **Ideal torsion pendulum**

Any twisting of the wire is inevitably associated with mechanical deformation. The wire resists such deformation by developing a restoring torque, M, which acts to restore the wire to its untwisted state. For relatively small angles of twist, the magnitude of this torque is assumed directly proportional to the twist angle. Hence, we can write:

$$M = -k\theta \tag{9.3.898}$$

where k is the "torsion constant" of that particular material wire (see section Mechanical Engineering page 8404).

So we have:

$$M = J_z \frac{\mathrm{d}^2\theta}{\mathrm{d}t^2} = -k\theta \tag{9.3.899}$$

Hence the differential equation:

$$\frac{\mathrm{d}^2\theta}{\mathrm{d}t^2}+\frac{k}{J_z}\theta=0 \tag{9.3.900}$$

By analogy with the simple pendulum and physical pendulum where we had a similar differential equation to a given factor, we get:

$$\boxed{T=2\pi\sqrt{\frac{J_z}{k}}} \tag{9.3.901}$$

We conclude that when a torsion pendulum is perturbed from its equilibrium state (i.e., $\theta=0$), it executes torsional oscillations about this state at a fixed frequency, ω, which depends only on the torque constant of the wire and the moment of inertia of the disk. Note, in particular, that the frequency is independent of the amplitude of the oscillation (provided θ remains small enough).

Torsion pendulums are often used for time-keeping purposes. For instance, the balance wheel in a mechanical wristwatch is a torsion pendulum in which the restoring torque is provided by a coiled spring.

9.3.10.7 Foucault's Pendulum

The Foucault pendulum is a great experience to account for the rotation of the Earth. While it had long been known that the Earth rotates, the introduction of the Foucault pendulum in 11851 (holocene calendar) was the first simple proof of the rotation in an easy-to-see experiment. Today, Foucault pendulums are popular displays in science museums and universities.

There are several mathematical methods to analyse the behaviour of the Foucault pendulum. We have chosen to present the simplest one which requires little computational pages.

But first let us give a little explanatory text may be relevant as this experience is important and so well known.

Foucault's experiment aims to demonstrate that the Earth rotates on itself as we have just say. We push a pendulum (a mass after a wire). He moved back and forth regularly in the same direction. If we take it in a car and we do not turn too sharply, the pendulum don't care of the turns you take with the car: he continues to fight in the same direction. This is because a simple pendulum always oscillate in the same plane, despite the movements of its support.

This is why the French physicist Léon Foucault had the idea of attaching a heavy pendulum to a 67 meters long wire under the dome of the Pantheon, in the presence of Napoleon III and some scholars:

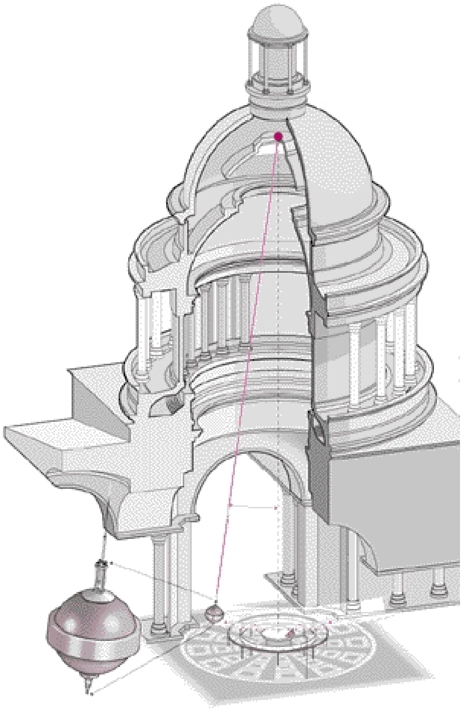

Figure 9.93: **Schematic view of Foucault's pendulum (source: ?)**

At each of its whereabouts, the pendulum came modify a pile of sand where it left a mark. But the track was never in the same place: there were 3 to 4 millimetres of difference between a swing and the next one, 16 seconds later. The pendulum remained in the same plane, but the Pantheon, Paris, the Earth are revolving!

To introduce the maths, consider the figure below:

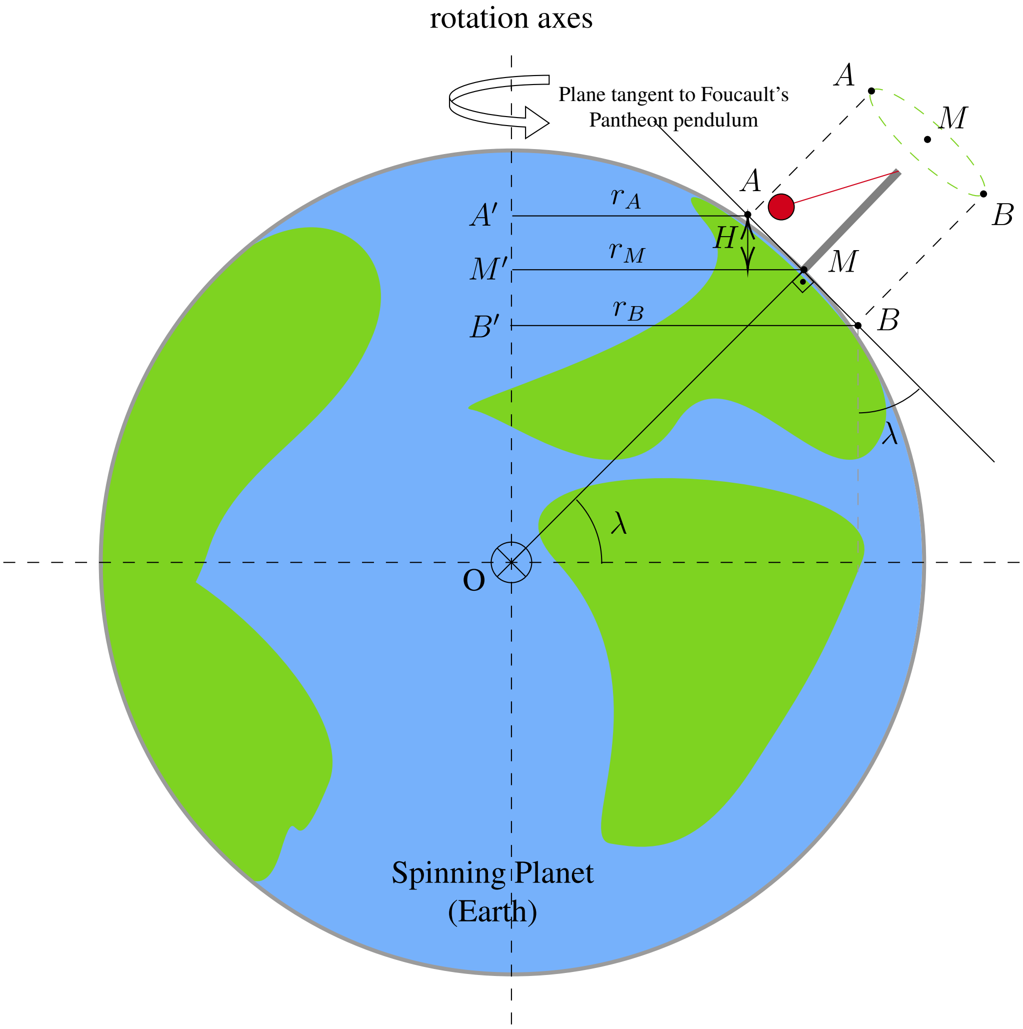

Figure 9.94: **Study diagram of Foucault's pendulum (not to scale obviously!)**

We consider that this is the view from a geocentric reference (Earth) seen in section on a plane containing the axis of rotation.

The size of the pendulum is obviously exaggerated in the figure above. However, it still oscillates in a meridian plane, between A and B (a terrestrial observer sees the line $\overline{AB}$ rotate relative to the Earth's surface by the green circle, seen in perspective, in the reverse direction).

Given T the rotation period of A (or B). The speed of A (v_a), on this circle is due to the fact that in the geocentric frame of reference, the point M, to the vertical of the point of suspension at the latitude λ, and the point on the Earth's surface coinciding with A at a given instant, does not have the same speed in the geocentric frame of reference: the point M being furthest from the axis of rotation of the Earth it is faster than A (same for the speed B that is higher than the speed of M).

Indeed, as $r_B > r_M > r_A$ and that $v = \omega R$, we have $v_B > v_M > v_A$.

The difference is of these speeds can easily be calculated assuming that rotation Earth's reasoning is uniform over a period of one day (sidereal) T_0.

We know that:

$$v = \omega r = \frac{2\pi}{T} \tag{9.3.902}$$

From this it easily follows that:

$$\Delta v = \frac{2\pi}{T_0}(r_m - r_A) \tag{9.3.903}$$

Since in the triangle AHM we have:

$$r_M - r_A = \overline{HM} = \overline{AM}\sin(\lambda) \tag{9.3.904}$$

Then:

$$\Delta v = \frac{2\pi}{T_0}\overline{AM}\sin(\lambda) \tag{9.3.905}$$

But we know Δv is just on green circle:

$$\Delta v = v_a = \frac{2\pi}{T}\overline{AM} \tag{9.3.906}$$

Therefore by equating and simplifying we get:

$$\boxed{T = \frac{T_0}{\sin(\lambda)}} \tag{9.3.907}$$

Remark

The direction of rotation of the pendulum is clockwise for an observer in the Northern Hemisphere; and counter-clockwise for an observer in the Southern Hemisphere.

✍**Example:**

The period of the Pantheon pendulum is 16.5 [s], the maximum amplitude of 6 [m] and the damping time of 6 [h]. We can observe a displacement of several millimetres at each return of the pendulum.

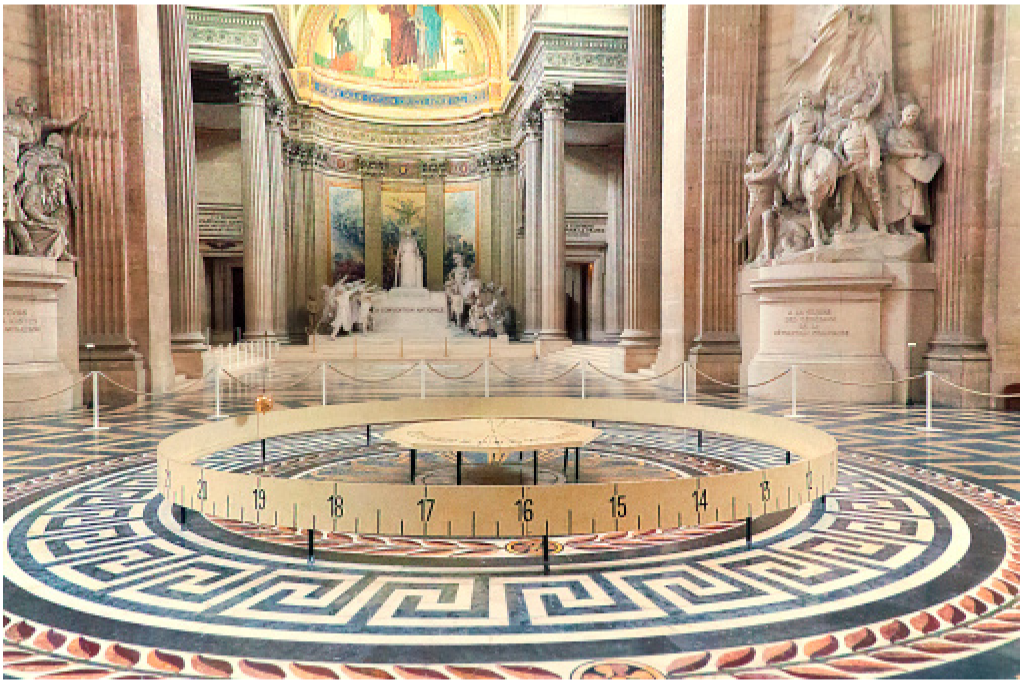

Figure 9.95: **Photo of Foucault's pendulum in Pantheon (Paris/France)**

At the poles (where the angle is $\pi/2$ [rad] and the sinus is equal to 1), the period of the pendulum equals that of the Earth and is therefore 24 [h]. At the equator (where the angle is equal to 0 [rad] and the sinus is equal to 0), the period of rotation of the oscillation plane is infinite: the plane of oscillation is stationary relative to the Earth! A Paris, where the latitude angle is equal $48°52'$ we have:

$$T=\frac{24}{\sin(48°52')}=\frac{24}{0.749}\cong 32 \tag{9.3.908}$$

That is to say in degrees: $11°$ [h^{-1}]. And this corresponds to the value given on Internet relatively to the Foucault's pendulum at the Pantheon!

Place	**Latitude**	Rotation time of the oscillation plane
North Pole	90°N	23 hours 56 minutes
Mourmansk (Russia)	68°58′N	25 hours 42 minutes
Oslo (Norway)	59°55′N	27 hours 45 minutes
Paris (France)	48°50′N	31 hours 57 minutes
Toulouse (France)	43°37′N	34 hours 51 minutes
Alexandria (Egypt)	31°13′N	46 hours 18 minutes
N'Djamena (Tchad)	12°10′N	114 hours 10 minutes
Equator	0°	Infinite : the oscillation plane remains fixed
The Cap (South Africa)	−33°94′S	42 hours 52 minutes
South Pole	90°S	23 hours 56 minutes

Table 9.20: **Foucault pendulum various periods**

However, the importance of Foucault's pendulum is elsewhere ...

The pendulum oscillation plane is fixed in reality and it is the rotation of the Earth on itself that result in an apparent rotation. But finally ... what is the reference system?

Indeed, all motions are relative. If the Earth is rotating, it because it's compared to something else. We can not talk about a movement without defining a frame of reference. The question that therefore arises is then to know relatively to what reference frame the pendulum oscillates in a fixed plane???

The first idea that comes to mind is to say that the pendulum plane is fixed relatively to the Sun. But if Foucault had managed to build a pendulum capable of oscillating long enough, say for a month, he would have noticed that the plane of oscillation also derived from the position of the Sun. Our star is therefore not part of the reference frame we are looking for!

Perhaps it is then necessary to consider the stars near the Sun? But again, if the experience could last long enough, it would show that the plane of oscillation clearly moves relative to the stars after a few years. What object to choose then? The galactic center, the Andromeda galaxy, the local group, the local superclusters? Each of these objects give the illusion of being stationary relative to the plane of the oscillations, but would end, after an increasingly long time, by revealing a drift.

Finally, as a last resort, we can consider the most distant objects, galaxies or quasars located billions of light-years away. With this reference system, and if the experience of Foucault was feasible, the plan of oscillation would finally be fixed and there would be no drift. So it is that in considering the most distant objects in fact the observable Universe as a whole, that we can get a reference frame in which the plane of oscillation stabilizes.

Foucault's pendulum then don't care of the presence of the Earth, the Sun (actually a G2V-type star, aka yellow dwarf) or the Galaxy. A part of its movement is directly dictated by the Universe as a whole. This experience highlights a kind of mysterious link between each point and the entire Universe. Until further notice, the nature of that relationship is unknown.

A similar conclusion was drawn by the Austrian physicist Ernst Mach in the late 119th century (we will talk of the "Mach's principle" in the section of Special Relativity).

According to Newtonian physics, the product of the mass of a body by its acceleration is equal to the force applied on it. Therefore, for a given force, the more massive an object, the more its acceleration is low. From this point of view, the mass is therefore a measure of the inertia of the body, that is to say its ability to resist to a force.

Now suppose that all matter in the Universe disappears, except for that body. The latter is then completely isolated and no force is exerted on it. This means, according to Newtonian physics, the product of its mass by its acceleration is zero. But the acceleration can not be equal to zero. Indeed, as all matter in the Universe is gone, there is no reference system against which to set the speed or acceleration. The latter is indefinite and not zero. From a mathematical point of view, there is only one possibility, that the mass of the body is zero!

This reasoning shows that the mass and inertia of a body are not really the properties of the object itself, but rather the result of an interaction with the rest of the Universe. Just as the Foucault pendulum, Mach's principle shows us that there must be some sort of connection between the local properties of a body and the global properties of the Universe. As in the previous case, the nature of this mysterious connection need to be determined.

9.3.10.8 Huygens' Pendulum (and brachistochrone curve)

We seek to build a pendulum whose period is independent of the amplitude (and not just by approximation as we have seen above!), that it is customary to name "rigorous isochronism". For this we have two cycloidal lamella at symmetrical positions and determined as shown in the figure below:

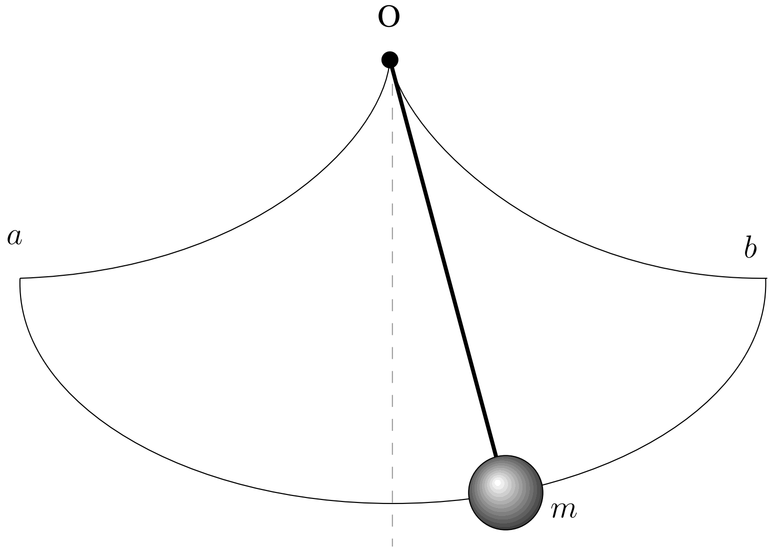

Figure 9.96: **Schematic Huygens' pendulum**

From this moment such pendulum applied to the measurement of time are known as "Coster clock", and at present all of these clocks manufactured under Huygen's license are in museums (the oldest known Huygens-style pendulum clock is dated 11657 - according holocene calendar - and can be seen at the Museum Boerhaave in Leiden) or in private collections.

Figure 9.97: **Reproduction of a coster clock (source: Lamazares Gil)**

The choice of the cycloid (also named "orthocycloïde") is because it is a "brachistochrone curve" (see definition below) and since the work of Christian Huygens in 11659 (holocene calendar), we also know that it is a "tautochronous curve" or "isochrone curve[19]" (some pendulums in modern watches have traditionally this form). That is to say that the bodies that fall into an inverted cycloid reach the lowest point at the same time, in any height they begin to fall (and for the pendulum independently of the starting amplitude - for small amplitudes only - they will reach the lowest point a the same time!).

So contrary to popular belief, the fastest way for a falling body on a solid support is not the straight line!

Indeed, one of the most famous problems of the history of mathematics is the "brachistochrone problem" which is to find the curve along which a particle would slide from one point to another in the shortest time being subject to a uniform field of gravity. This problem was posed by Johann Bernoulli in 11696 (holocene calendar) as a challenge for mathematicians of his day (and that was a really important challenge!!!). The solution was found by Johann Bernoulli himself and his brother Jacques Bernoulli, Isaac Newton, Gottfried Wilhelm Leibniz and the Marquis de l'Hospital. The brachistochrone problem is important in the development of mathematics and proves to be a major application of the method of variation calculus.

To introduce the corresponding maths we consider the two points A and B in the gravity field a material point m moving without friction on a curve of ends A and B. As already mentioned we want to determine the curve, named "brachistochrone", wherein the travel time is minimal when the point m starts from the point with a zero velocity.

Let us consider the figure below:

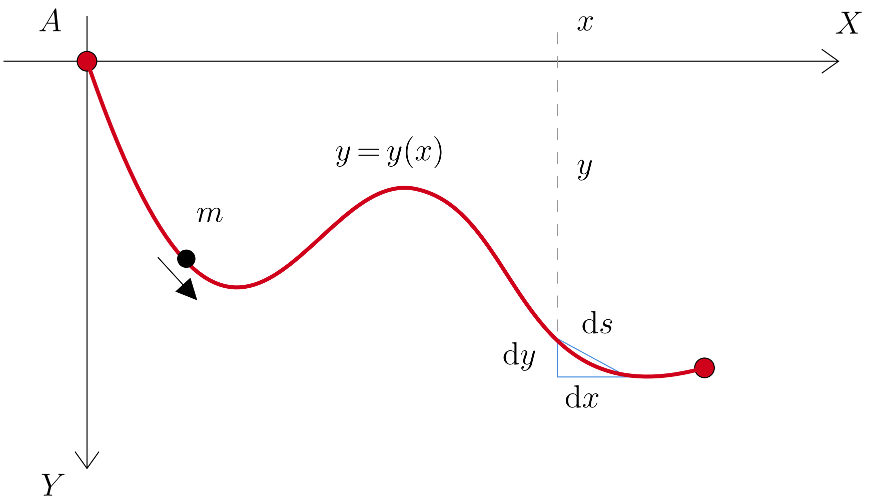

Figure 9.98: **Typical path to attack the brachistochrone problem without bias**

At the x-coordinate on the path plot above, the lost potential energy is $E_p = mgy$, equivalent to the kinetic energy gained by the material point from the start such as:

$$\frac{1}{2}mv^2 = mgh \tag{9.3.909}$$

---

[19] Remember that "brachistochrone" means "shortest time" and "tautochrone" means "same time".

Hence without too many surprises we get the "free fall speed in vacuum":

$$\boxed{v=\sqrt{2gh}} \tag{9.3.910}$$

The speed v is measured along the curve so that we have to rewrite the expression in horizontal and vertical components:

We will put that s is the curvilinear abscissa, $\mathrm{d}s$ the increase of this distance along the curve (see section Differential Geometry page 2850). The quantities $\mathrm{d}x$ and $\mathrm{d}y$ are the horizontal and vertical components of $\mathrm{d}s$.

Therefore:

- $\mathrm{d}s/\mathrm{d}t$ represents the speed along the curve
- $\mathrm{d}x/\mathrm{d}t$ the x component of the speed
- $\mathrm{d}x$ and $\mathrm{d}y$ are given by the Pythagorean theorem in exactly the same way as we did during our study of the Lagrangian formalism in the section of Analytical Mechanics:

$$v=\frac{\mathrm{d}s}{\mathrm{d}t}=\frac{\sqrt{\mathrm{d}x^2+\mathrm{d}y^2}}{\mathrm{d}t}=\sqrt{1+\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2}\frac{\mathrm{d}x}{\mathrm{d}t}=\sqrt{1+(y'(x))^2}\frac{\mathrm{d}x}{\mathrm{d}t} \tag{9.3.911}$$

By inserting the obtained equation from the principles of dynamics:

$$v=\sqrt{2gh}=\sqrt{2gy(x)}=\sqrt{1+(y'(x))^2}\frac{\mathrm{d}x}{\mathrm{d}t} \tag{9.3.912}$$

A simple integration then gives us the expression t to minimize:

$$t=\int\sqrt{\frac{1+(y'(x))^2}{2gy(x)}}\mathrm{d}x \tag{9.3.913}$$

We end up the with a function similar to the one we had in our study of a practical case of the Lagrangian formalism.

The challenge now is to find the minimum reached by t among all possible functions $y(x)$ satisfying the constraints:

$$y(x=0)=0 \qquad y(x=a)=b \tag{9.3.914}$$

The fundamental problem said to be of the "calculus of variations" is to search among all continuously differentiable functions $y=f(x)$ over a given interval $[A,B]$ for which the functions $f(A)$ and $f(B)$ are given known values, which make maximum or minimum the previous integral.

To apply this method, we start from the Euler-Lagrange equation (see section Analytical Mechanics page 3162):

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial Z(x,y,y')}{\partial y'}\right)-\frac{\partial Z(x,y,y')}{\partial y}=0 \tag{9.3.915}$$

which gives the extremum of the integral.

Similarly to an example that we saw during our study of the Lagrangian formalism (see section Analytical Mechanics page 3172) we put in our case:

$$Z(x,y,y')=\sqrt{\frac{1+(y'(x))^2}{2gy(x)}} \tag{9.3.916}$$

Therefore:

$$\begin{aligned}\frac{\partial Z}{\partial y}&=-\frac{1}{4}\frac{\sqrt{2}(1+y'^2}{\sqrt{\dfrac{1+y'^2}{gy}}gy^2}=-\frac{1}{4}\frac{\sqrt{2(1+y'^2}}{y\sqrt{gy}}\\ \frac{\partial Z}{\partial y'}&=\frac{\dfrac{2y'}{2gy}}{2\sqrt{\dfrac{1+y'^2}{2gy}}}=\frac{y'}{2gy}\sqrt{\frac{2gy}{1+y'^2}}=\frac{y'}{\sqrt{1+y'^2}\sqrt{2gy}}\end{aligned} \tag{9.3.917}$$

We wish to inject the last two relations in the Euler-Lagrange equation:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial Z(x,y,y')}{\partial y'}\right)-\frac{\partial Z(x,y,y')}{\partial y}=0 \tag{9.3.918}$$

but we anticipate relatively easily that the derivative with respect to x will give us an indigestible monster to simplify (I tried ... but I have the excuse of not being good at math).

We will then use the Beltrami's identity proved in the section of Analytical Mechanics (see page 3177) that is written with the above selected notation:

$$Z-y'\frac{\partial Z}{\partial y'}=c^{te} \tag{9.3.919}$$

that we have the right to do as the Beltrami 's condition here is satisfied:

$$\frac{\partial Z}{\partial t}=0 \tag{9.3.920}$$

Which gives us:

$$\sqrt{\frac{1+y'^2}{2gy}}-y'\frac{y'}{\sqrt{1+y'^2}\sqrt{2gy}}=c^{te} \tag{9.3.921}$$

Thus after rearranging:

$$\frac{\sqrt{1+y'^2}\sqrt{1+y'^2}}{\sqrt{2gy}\sqrt{1+y'^2}}-y'\frac{y'}{\sqrt{1+y'^2}\sqrt{2gy}}=\frac{\sqrt{1+y'^2}\sqrt{1+y'^2}-y'^2}{\sqrt{1+y'^2}\sqrt{2gy}}=\frac{1}{\sqrt{1+y'^2}\sqrt{2gy}}=c^{te} \tag{9.3.922}$$

So finally:

$$\frac{1}{\sqrt{1+y'^2}\sqrt{2gy}}=c^{te} \tag{9.3.923}$$

Or written in another way:

$$y(1+y'^2)=\frac{1}{2gc^{te2}}=K \tag{9.3.924}$$

where the constant K is only $-D$, the maximal point reached by the mobile. More explicitly:

$$y\left(1+\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2\right)=\frac{1}{2gc^{te2}}=K \tag{9.3.925}$$

We must solve this differential equation to find the function that provides the fastest path. Let's us focus on it in the following form:

$$y\left(1+\left(\frac{\mathrm{d}x}{\mathrm{d}t}\right)^2\right)=K \tag{9.3.926}$$

and let us recall that on the figure above we have:

$$\frac{\mathrm{d}y}{\mathrm{d}x}=\tan(\theta) \tag{9.3.927}$$

Then we have (see section Trigonometry page 2519):

$$y(1+\tan^2(\theta))=\frac{y}{\cos^2(\theta)}=K \tag{9.3.928}$$

Hence:

$$y=K\cos^2(\theta)=\frac{K}{2}(1+\cos(2\theta)) \tag{9.3.929}$$

Note that we have (still using trigonometric identities):

$$\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}\theta}&=\frac{\mathrm{d}x}{\mathrm{d}y}\frac{\mathrm{d}y}{\mathrm{d}\theta}=-\frac{1}{\tan(\theta)}K\sin(2\theta)=-\frac{1}{\tan(\theta)}K2\tan(\theta)\cos^2(\theta)=-2K\cos^2(\theta)\\&=-2K\frac{(1+\cos(2\theta))}{2}=-K(1+\cos(2\theta))\end{aligned} \tag{9.3.930}$$

Therefore:

$$\frac{\mathrm{d}x}{\mathrm{d}\theta}=-K(1+\cos(2\theta)) \tag{9.3.931}$$

Which is easy to integrate (see section Differential and Integral Calculus page 1534):

$$\begin{aligned}x&=-K\left(\theta+\frac{1}{2}\sin(2\theta)\right)+c^{te}=-\frac{2}{2}K\left(\theta+\frac{1}{2}\sin(\theta)\right)+c^{te}\\&=-\frac{K}{2}(2\theta+\sin(2\theta))+c^{te}\end{aligned} \tag{9.3.932}$$

So we have at this point (for recall):

$$\begin{aligned}x&=-\frac{K}{2}(2\theta+\sin(2\theta))+c^{te}\\y&=\frac{K}{2}(1+\cos(2\theta))\end{aligned} \tag{9.3.933}$$

Let us put to simplify the writing $\alpha=2\theta$, we have then:

$$\begin{aligned}x&=-\frac{K}{2}(\alpha+\sin(\alpha))+c^{te}\\ y&=\frac{K}{2}(1+\cos(\alpha))\end{aligned} \tag{9.3.934}$$

Let us recall now that we have the initial condition:

$$y(x=0)=0 \tag{9.3.935}$$

and as K is not zero, this requires that in the prior previous relation that:

$$\cos(\alpha_{x=0})=-1 \tag{9.3.936}$$

and therefore that:

$$\alpha_{x=0}=-\pi\Leftrightarrow\theta_{x=0}=-\frac{\pi}{2} \tag{9.3.937}$$

Therefore, we must have:

$$x=-\frac{K}{2}(-\pi+\sin(-\pi))+c^{te}=0 \tag{9.3.938}$$

and we deduce immediately that:

$$c^{te}=-\frac{K\pi}{2} \tag{9.3.939}$$

Since then:

$$\begin{aligned}x&=-\frac{K}{2}(\alpha+\sin(\alpha))-\frac{K\pi}{2}\\ y&=\frac{K}{2}(1+\cos(\alpha))\end{aligned} \tag{9.3.940}$$

To close that subject, let us do the traditional variable change:

$$\alpha=\varphi-\pi\qquad a=\frac{K}{2} \tag{9.3.941}$$

It comes then:

$$\begin{aligned}x&=-a((\varphi-\pi)+\sin(\varphi-\pi))-a\pi=-a(\varphi+\sin(\varphi-\pi))=-a(\varphi-\sin(\varphi))\\ y&=a(1+\cos(\alpha)=a(1+\cos(\varphi-\pi))=a(1-\cos(\varphi))\end{aligned} \tag{9.3.942}$$

So in the end:

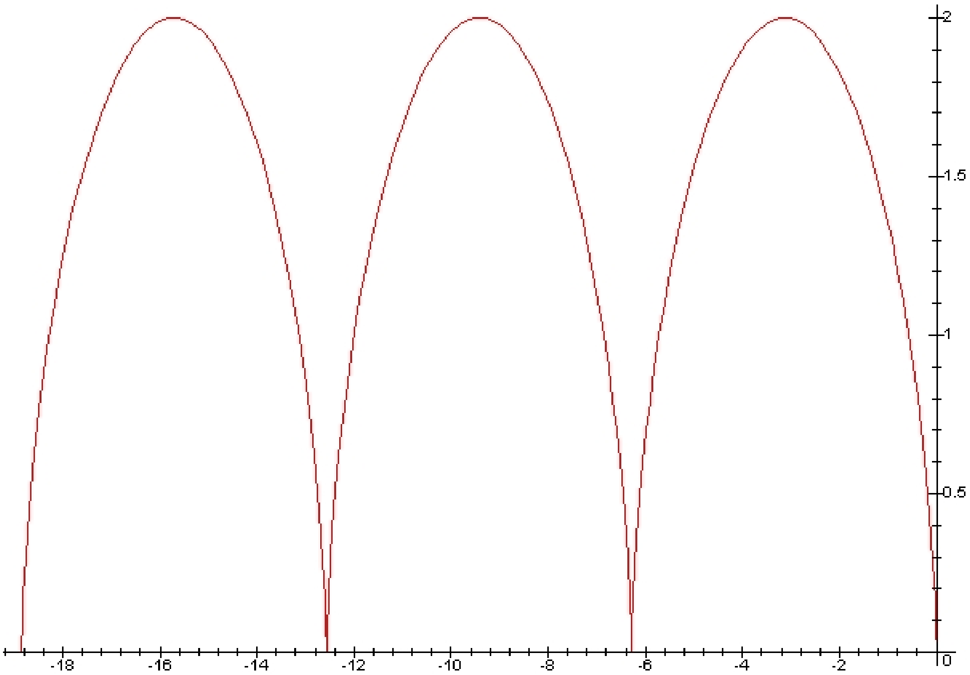
$$\begin{aligned}x&=-a(\varphi-\sin(\varphi))\\ y&=a(1-\cos(\varphi))\end{aligned} \tag{9.3.943}$$

As the sign of the coefficient a of x that has for only effect a translation along the X axis, it is customary to represent that pair of equations in the following form where we recognize the parametric equations of a cycloid curve (see section Analytical Geometry page 2814):

$$\boxed{\begin{aligned}x&=a(\theta-\sin(\theta))\\ y&=a(1-\cos(\theta))\end{aligned}} \tag{9.3.944}$$

By putting $a=1$ we have in Maple™ 4.00b:

```
>plot([theta-sin(theta),1-cos(theta),theta=0..6*Pi]);
```



This has to be compared with the intuitive answers that humans being give when they try to guess the fastest curve (in red below the brachistochrone curve and in blue... most human beings answers):

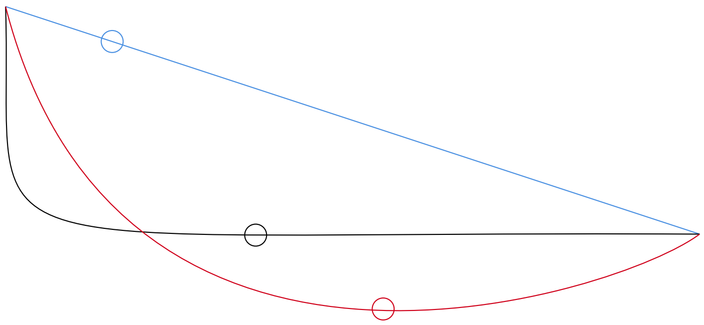


Figure 9.99: **Comparison of the brachistochrone with other intuitive paths**

Given the derivatives:

$$\begin{aligned}\frac{\mathrm{d}x}{\mathrm{d}\theta}&=a(1-\cos(\theta))\\ \frac{\mathrm{d}y}{\mathrm{d}\theta}&=a\sin(\theta)\end{aligned} \tag{9.3.945}$$

Therefore:

$$(\mathrm{d}_\theta x)^2+(\mathrm{d}_\theta y)^2=a^2\left[(1-2\cos(\theta)+\cos^2(\theta)+\sin^2(\theta)\right]=2a^2\left(1-\cos(\theta)\right) \tag{9.3.946}$$

The conservation of energy:

$$\frac{1}{2}mv^2=mgy \tag{9.3.947}$$

is then written as we know:

$$v=\frac{\mathrm{d}s}{\mathrm{d}t}=\sqrt{2gy} \tag{9.3.948}$$

hence:

$$\mathrm{d}t=\frac{\mathrm{d}s}{\sqrt{2gy}}=\frac{\sqrt{(\mathrm{d}_\theta x)^2+(\mathrm{d}_\theta y)^2}}{\sqrt{2gy}}=\frac{a\sqrt{2(1-\cos(\theta))\mathrm{d}\theta}}{\sqrt{2ga(1-\cos(\theta)}}=\sqrt{\frac{a}{g}}\mathrm{d}\theta \tag{9.3.949}$$

Therefore the time required to go from top to bottom of the cycloid described by the Huygens' pendulum is:

$$T=\int\limits_0^\pi\sqrt{\frac{a}{g}}\mathrm{d}\theta=\pi\sqrt{\frac{a}{g}} \tag{9.3.950}$$

This term therefore only dependent on fixed parameters and not of the amplitude of the pendulum!

The statement in 11696 (holocene calendar) of the brachistochrone the problem can be considered as the true birth of the calculus of variations, because it is this problem which prompted the search for general methods gradually developed in the context of a real scientific (and business...) competition.

Remark

The brachistochrone of a surface is a curve on which a material punctual mass slide without friction when placed in a uniform gravitational field so that travel time is minimal among all curves joining two fixed points. In other words, the brachistochrone is the shortest lines in time, while the geodesic (see section Tensor Calculus page 5747) are the curves of the shortest distance for a given fixed time interval!

9.3.10.9 Double Pendulum

A double pendulum is a pendulum with another pendulum attached to its end, and is a simple physical system that exhibits rich dynamic behaviour with a strong sensitivity to initial conditions.

The double pendulum problem is a classic application of the Lagrangian formalism and of Chaos Theory and so verbatim a nice school example of non-linear physics.

Here is a figure of how it is often described (the x and y are positive on both axes represented below!):

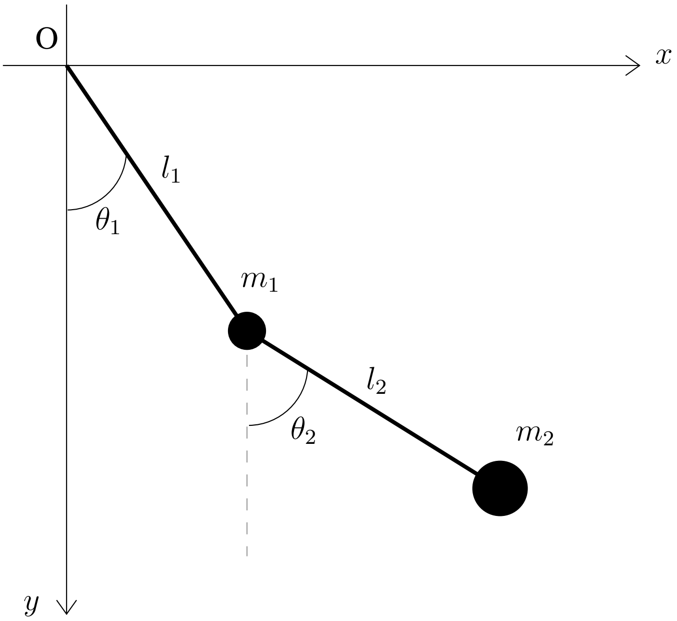

Figure 9.100: **Illustration of the ideal double pendulum**

The position of the mass m_1 will be given by the coordinates (x_1, y_1) and that of the mass m_2 - linked to m_1 and therefore not independent - will be given by the coordinates (x_2, y_2).

The best is to reduce the study of the system through the generalized coordinates (θ_1, θ_2) trough the transformations:

$$x_1 = l_1 \sin(\theta) \qquad y_1 = l_1 \cos(\theta_1) \tag{9.3.951}$$

and:

$$x_2 = x_1 + l_2 \sin(\theta_2) \qquad y_2 = y_1 + l_2 \cos(\theta_2) \tag{9.3.952}$$

So in Cartesian coordinates and using the traditional notation of the Lagrangian formalism, the kinetic energy is then:

$$T = \frac{1}{2} m_1 v_1^2 + \frac{1}{2} m_2 v_2^2 \tag{9.3.953}$$

and as:

$$\begin{aligned} v_1 &= \left\| \frac{\mathrm{d}\vec{r}_1}{\mathrm{d}t} \right\| = \left\| \frac{\mathrm{d}}{\mathrm{d}t} \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} \right\| = \left\| \frac{\mathrm{d}}{\mathrm{d}t} \begin{pmatrix} l_1 \sin(\theta_1) \\ l_1 \cos(\theta_1) \end{pmatrix} \right\| = \left\| l_1 \begin{pmatrix} \dot{\theta}_1 \cos(\theta_1) \\ -\dot{\theta}_1 \sin(\theta_1) \end{pmatrix} \right\| \\ &= \sqrt{(l_1 \dot{\theta}_1 \cos(\theta))^2 + (-l_1 \dot{\theta}_1 \sin(\theta_1)^2} = \sqrt{l_1^2 \dot{\theta}_1^2 \cos^2(\theta_1) + l_1^2 \dot{\theta}_1^2 \sin^2(\theta_1)} = \dot{\theta}_1 l_1 \end{aligned} \tag{9.3.954}$$

and:

$$\begin{aligned}v_2&=\left\|\frac{\mathrm{d}\vec{r}_2}{\mathrm{d}t}\right\|=\left\|\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix}x_2\\y_2\end{pmatrix}\right\|=\left\|\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix}x_1+l_2\sin(\theta_2)\\y_1+l_2\cos(\theta_2)\end{pmatrix}\right\|=\left\|\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix}l_1\sin(\theta_1)+l_2\sin(\theta_2)\\l_1\cos(\theta_1)+l_2\cos(\theta_2)\end{pmatrix}\right\|\\&=\left\|\begin{pmatrix}l_1\dot{\theta}_1\cos(\theta_1)+l_2\dot{\theta}_2\cos(\theta_2)\\-l_1\dot{\theta}_1\sin(\theta_1)-l_2\dot{\theta}_2\sin(\theta_2)\end{pmatrix}\right\|=\sqrt{(l_1\dot{\theta}_1\cos(\theta_1)+l_2\dot{\theta}\sin(\theta_2)}\\&=\sqrt{(l_1\dot{\theta}_1\cos(\theta_1)+l_2\dot{\theta}_2\cos(\theta_2))^2+(-l_1\dot{\theta}_1\sin(\theta_1)-l_2\dot{\theta}_2\sin(\theta_2))^2}\\&=\sqrt{\begin{matrix}l_1^2\dot{\theta}_1^2\cos^2(\theta_1)+2l_1l_2\dot{\theta}_1\dot{\theta}_2\cos(\theta_1)\cos(\theta_2)+l_2^2\dot{\theta}_2^2\cos^2(\theta_2)+l_1^2\dot{\theta}_1^2\sin^2(\theta_1)\\+2l_1l_2\dot{\theta}_1\dot{\theta}_2\sin(\theta_1)\sin(\theta_2)+l_2^2\dot{\theta}_2^2\sin^2(\theta_2)\end{matrix}}\\&=\sqrt{l_1^2\dot{\theta}_1^2+l_2^2\dot{\theta}^2+2l_1l_2\dot{\theta}_1\dot{\theta}_2(\cos(\theta_1)\cos(\theta_2)+\sin(\theta_1)\sin(\theta_2))}\\&=\sqrt{l_1^2\dot{\theta}_1^2+l_2^2\dot{\theta}_2^2+2l_1l_2\dot{\theta}_1\dot{\theta}_2\cos(\theta_1-\theta_2)}\end{aligned}\tag{9.3.955}$$

Then we have:

$$\begin{aligned}T&=\frac{1}{2}m_1v_1^2+\frac{1}{2}m_2v_2^2=\frac{1}{2}m_2v_2^2=\frac{1}{2}m_1(\dot{\theta}l_1)^2+\frac{1}{2}m_2\left(\sqrt{l_1^2\dot{\theta}_1^2+l_2^2\dot{\theta}_2^2+2l_1l_2\dot{\theta}_1\dot{\theta}_2\cos(\theta_1-\theta_2)}\right)^2\\&=\frac{1}{2}m_1\dot{\theta}_1^2l_1^2+\frac{1}{2}m_2\left(l_1^2\dot{\theta}_1^2+l_2^2\dot{\theta}_2^2+2l_1l_2\dot{\theta}\dot{\theta}_2\cos(\theta_1-\theta_2)\right)\\&=\frac{1}{2}(m_1+m_2)\dot{\theta}_2l_1^2+\frac{1}{2}m_2\left(l_2^2\dot{\theta}_2^2+2l_1l_2\dot{\theta}\dot{\theta}_2\cos(\theta_1-\theta_2)\right)\end{aligned}\tag{9.3.956}$$

For the potential energy we have (the sign is negative because the masses are below the point 0):

$$V=-m_1gy_1-m_2gy_2=-m_1gl_1\cos(\theta_1)-m_2g(l_1\cos(\theta_1)+l_2\cos(\theta_2)\tag{9.3.957}$$

The Lagrangian (see section Analytical Mechanics page 3152) is therefore given by:

$$\begin{aligned}&L=T-V=\frac{1}{2}(m_1+m_2)\dot{\theta}_1l_1^2+\frac{1}{2}m_2l_2^2\dot{\theta}_2^2+m_2l_1l_2\dot{\theta}_1\dot{\theta}_2\cos(\theta_1-\theta_2)\\&\quad+(m_1+m_2)gl_1\cos(\theta_1)+m_2gl_2\cos(\theta_2))\end{aligned}\tag{9.3.958}$$

We now use the Euler-Lagrange equation with the chosen generalized coordinates:

$$\begin{aligned}\frac{\partial L}{\partial\theta_1}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial\dot{\theta}_1}=0\\\frac{\partial L}{\partial\theta_2}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial\dot{\theta}_2}=0\end{aligned}\tag{9.3.959}$$

We then have for θ_1:

$$\begin{aligned}
&\frac{\partial L}{\partial \theta_1}=-m_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin(\theta_1-\theta_2)-(m_1+m_2) g l_1 \sin(\theta_1)\\
&\frac{\partial L}{\partial \dot{\theta}_1}=(m_1+m_2)\dot{\theta}_1 l_1^1+m_2 l_1 l_2 \dot{\theta}_2 \cos(\theta_1-\theta_2)\\
&\frac{\mathrm{d}}{\mathrm{d}t}=(m_1+m_2)\ddot{\theta}_1 l_1^2+m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_2 \frac{\mathrm{d}}{\mathrm{d}t}\cos(\theta_1-\theta_2)\\
&=(m_1+m_2)\ddot{\theta} l_1^2+m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_2(-\dot{\theta}_1 \sin(\theta_1-\theta_2)+\dot{\theta}_2 \sin(\theta_1-\theta_2))\\
&=(m_1+m_2)\ddot{\theta} l_1^2+m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_2(\dot{\theta}_2-\dot{\theta}_1)\sin(\theta_1-\theta_2)
\end{aligned} \tag{9.3.960}$$

So we have ultimately for the Euler-Lagrange equation with the generalized coordinate θ_1:

$$\begin{aligned}
&-m_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin(\theta_1-\theta_2)-(m_1+m_2) g l_1 \sin(\theta_1)\\
&-(m_1+m_2)\ddot{\theta}_1 l_1^2-m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)-m_2 l_1 l_2 \dot{\theta}_2(\dot{\theta}_2-\dot{\theta}_1)\sin(\theta_1-\theta_2)\\
&=-(m_1+m_2) g l_1 \sin(\theta_1)-(m_1+m_2)\ddot{\theta}_1 l_1^2-m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)-m_2 l_1 l_2 \dot{\theta}_2^2 \sin(\theta_1-\theta_2)\\
&=0
\end{aligned} \tag{9.3.961}$$

We have also for θ_2:

$$\begin{aligned}
&\frac{\partial L}{\partial \theta_2}=-m_2 l_1 l_2 \dot{\theta}_1 \dot{\theta}_2 \sin(\theta_1-\theta_2)-m_2 g l_2 \sin(\theta_2)\\
&\frac{\partial L}{\partial \dot{\theta}_2}=m_2 l_2^2 \dot{\theta}_2+m_2 l_1 l_2 \dot{\theta}_1 \cos(\theta_1-\theta_2)\\
&\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\theta}_2}=m_2 l_2^2 \ddot{\theta}_2+m_2 l_1 l_2 \ddot{\theta}_1 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_1(\dot{\theta}_2-\dot{\theta}_1)\sin(\theta_1-\theta_2)
\end{aligned} \tag{9.3.962}$$

So we have ultimately for the Euler-Lagrange equation with the generalized coordinate θ_2:

$$\begin{aligned}
&m_2 l_1 l_2 \dot{\theta} \dot{\theta}_2 \sin(\theta_1-\theta_2)-m_2 g l_2 \sin(\theta_2)\\
&-m_2 l_2^2 \ddot{\theta}_2-m_2 l_1 l_2 \ddot{\theta}_1 \cos(\theta_1-\theta_2)-m_2 l_1 l_2 \dot{\theta}_1(\dot{\theta}_2-\dot{\theta}_1)\sin(\theta_1-\theta_2)\\
&=-m_2 g l_2 \sin(\theta_2)-m_2 l_2^2 \ddot{\theta}_2-m_2 l_1 l_2 \ddot{\theta}_1 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_1^2 \sin(\theta_1-\theta_2)=0
\end{aligned} \tag{9.3.963}$$

This gives us the finally the following system of differential equations:

$$\begin{aligned}
&(m_1+m_2) g l_1 \sin(\theta_1)+(m_1+m_2)\ddot{\theta}_1 l_1^2+m_2 l_1 l_2 \ddot{\theta}_2 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_2^2 \sin(\theta_1-\theta_2)=0\\
&m_2 g l_2 \sin(\theta_2)+m_2 l_2^2 \ddot{\theta}_2+m_2 l_1 l_2 \ddot{\theta}_1 \cos(\theta_1-\theta_2)+m_2 l_1 l_2 \dot{\theta}_1^2 \sin(\theta_1-\theta_2)=0
\end{aligned} \tag{9.3.964}$$

With Maple™ 4.00b this gives for the representation of the coordinates of m_2 over time:

```
> with(plots):
> with(plottools):

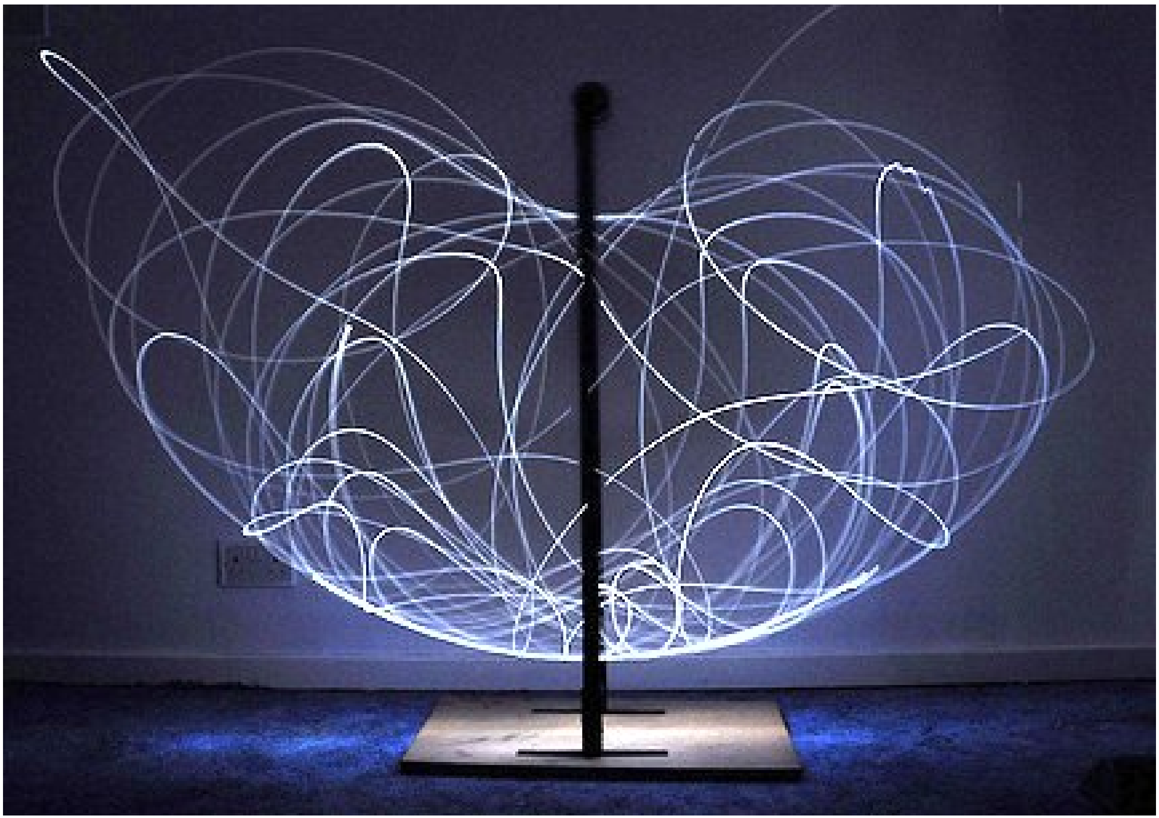

Figure 9.102: **Long exposure of double pendulum exhibiting chaotic motion tracked with a LED (source: Wikipedia)**

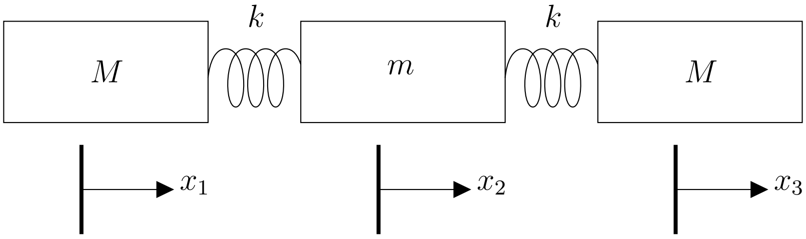
9.3.10.10 Triple linear coupled pendulum

Consider three masses on the x -axis joined by springs as shown in the figure below:



The spring forces are assumed to be linear (small displacements, Hooke's law as derived at page 3744), and the mass is constrained to stay on the x-axis.

Using a different coordinate for each mass, Newton's second law yields the set of equations:

$$\begin{aligned}\ddot{x}_1&=-\frac{k}{M}(x_1-x_2)\\ \ddot{x}_2&=-\frac{k}{m}(x_2-x_1)-\frac{k}{m}(x_2-x_3)\\ \ddot{x}_3&=-\frac{k}{M}(x_3-x_2)\end{aligned}\tag{9.3.965}$$

The system of masses is vibrating. We seek the common frequencies, ω, such that all masses vibrate at this same frequency. These are the normal modes. Let:

$$x_i=x_{i0}e^{\mathrm{i}\omega t},\quad i=1,2,3\tag{9.3.966}$$

Substituting this set into the previous set of equalities, we may rewrite it as:

$$\begin{pmatrix}\frac{k}{M} & -\frac{k}{M} & 0\\ -\frac{k}{m} & \frac{2k}{m} & -\frac{k}{m}\\ 0 & -\frac{k}{M} & \frac{k}{M}\end{pmatrix}\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}=+\omega^2\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}\tag{9.3.967}$$

with the common factor $e^{\mathrm{i}\omega t}$ divided out. We have a matrix-eigenvalue equation with the matrix asymmetric (see section Linear Algebra page 1997). The secular equation is:

$$\begin{vmatrix}\frac{k}{M}-\omega^2 & -\frac{k}{M} & 0\\ -\frac{k}{m} & \frac{2k}{m}-\omega^2 & -\frac{k}{m}\\ 0 & -\frac{k}{M} & \frac{k}{M}-\omega^2\end{vmatrix}=0\tag{9.3.968}$$

This leads to the following determinant:

$$\omega^2\left(\frac{k}{M}-\omega^2\right)\left(\omega^2-\frac{2k}{m}-\frac{k}{M}\right)=0\tag{9.3.969}$$

The eigenvalues are:

$$\omega^2=0,\quad\frac{k}{M},\quad\frac{k}{M}+\frac{2k}{m}\tag{9.3.970}$$

all real. The corresponding eigenvectors are determined by substituting the eigenvalues back into:

$$\begin{pmatrix} \frac{k}{M} & -\frac{k}{M} & 0 \\ -\frac{k}{m} & \frac{2k}{m} & -\frac{k}{m} \\ 0 & -\frac{k}{M} & \frac{k}{M} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = +\omega^2 \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \tag{9.3.971}$$

one eigenvalue at a time. For $\omega^2 = 0$, the above system, yields:

$$x_1 - x_2 = 0, \quad -x_1 + 2x_2 - x_3 = 0, \quad -x_2 + x_3 = 0 \tag{9.3.972}$$

Then we get:

$$x_1 = x_2 = x_3 \tag{9.3.973}$$

This describes pure translation with no relative motion of the masses and no vibration. For $\omega^2 = k/M$, the above system yields to:

$$x_1 = -x_3, \quad x_2 = 0 \tag{9.3.974}$$

The two outer masses are moving in opposite direction. The central mass is stationary. For $\omega^2 = k/M + 2k/m$, the eigenvector components are:

$$x_1 = x_3, \quad x_2 = -\frac{2M}{m} x_1 \tag{9.3.975}$$

The two outer masses are moving together. The central mass is moving opposite to the two outer ones. The net momentum is zero.

Any displacement of the three masses along the x -axis can be described as a linear combination of these three types of motion: translation plus two forms of vibration.

9.3.10.11 Inverted Pendulum

An inverted pendulum is a pendulum that has its center of mass above its pivot point. It is often implemented with the pivot point mounted on a cart that can move horizontally as shown in the photo below:

Figure 9.103: **A famous business application (SEGWAY™) of mobile inverted pendulum**

Most applications limit the pendulum to 1 degree of freedom by affixing the pole to an axis of rotation. Whereas a normal pendulum is stable when hanging downwards, an inverted pendulum is inherently unstable, and must be actively balanced in order to remain upright; this can be done either by applying a torque at the pivot point, by moving the pivot point horizontally as part of a feedback system, changing the rate of rotation of a mass mounted on the pendulum on an axis parallel to the pivot axis and thereby generating a net torque on the pendulum, or by oscillating the pivot point vertically. A simple demonstration of moving the pivot point in a feedback system is achieved by balancing an upturned broomstick on the end of one's finger. The inverted pendulum is a classic problem in dynamics and control theory and is used as a benchmark for testing control strategies. Arguably the most prevalent example of an inverted pendulum is a human being. A person with an upright body needs to make adjustments constantly to maintain balance whether standing, walking, or running.

The inverted pendulum is a superb academic example of the application of Lagrangian Mechanics to another coupled system than the that of the double pendulum seen previously. Moreover, we can make a very good parallel with the watch systems as they are used in many R&D departments of watch manufacturers.

For the mathematical study let us consider the following experiment (The rod is considered massless!):

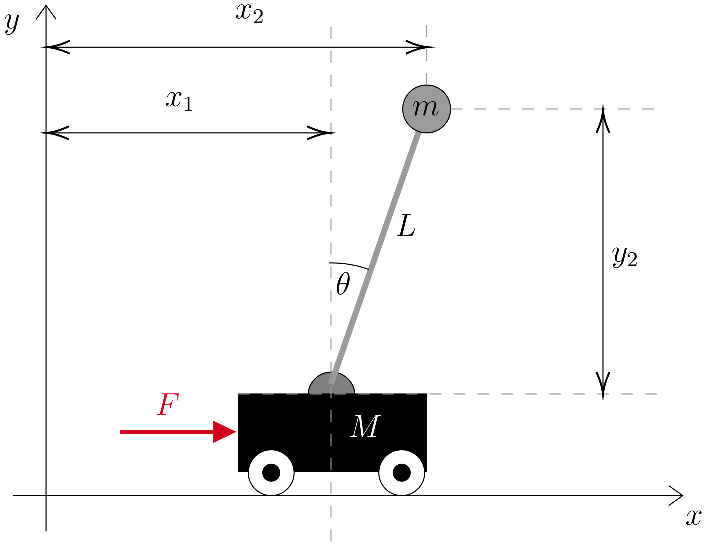


Figure 9.104: **A schematic drawing of the inverted pendulum on a cart**

The position of the mass base carriage M is x_1, the angle of the rod of length L is θ, the scalar force applied on the base of carriage is F. The coordinates of the weight at the extremity of the rod will be (x_2, y_2).

We will deduce the system of differential equations which describes the inverse pendulum dynamics using the Lagrange equations (see section Analytical/Lagrangian Mechanics page 3152).

The kinetic energy of the carriage and the extreme weight of the rod are therefore respectively:

$$\begin{aligned}E_{c,1}&=\frac{1}{2}M\dot{x}^2\\E_{c,2}&=\frac{1}{2}m(\dot{x}_2^2+\dot{y}_2^2)\end{aligned}\tag{9.3.976}$$

With:

$$\begin{aligned}x_2&=x_1+L\sin(\theta)\\y_2&=L\cos(\theta)\end{aligned}\tag{9.3.977}$$

such that:

$$\begin{aligned}\dot{x}_2&=\dot{x}_1+L\dot{\theta}\cos(\theta)\\\dot{y}_2&=-L\dot{\theta}\sin(\theta)\end{aligned}\tag{9.3.978}$$

Thus the total kinetic energy is written:

$$\begin{aligned}E_c=E_{c,1}+E_{c,2}&=\frac{1}{2}M\dot{x}_1^2+\frac{1}{2}m(\dot{x}_2^2+\dot{y}_2^2)=\frac{1}{2}M\dot{x}_1^2+\frac{1}{2}m\left((\dot{x}_1+L\dot{\theta}\cos(\theta))^2+(-L\dot{\theta}\sin(\dot{\theta}))^2\right)\\&=\frac{1}{2}M\dot{x}_1^2+\frac{1}{2}m\left(\dot{x}_1^2+2\dot{x}_1L\dot{\theta}\cos(\theta)+L^2\dot{\theta}^2\cos^2(\theta)+L^2\dot{\theta}^2\sin^2(\theta)\right)\\&=\frac{1}{2}M\dot{x}_1^2+\frac{1}{2}m\left(\dot{x}_1^2+2\dot{x}_1L\dot{\theta}\cos(\theta)+L^2\dot{\theta}^2\right)=\frac{1}{2}(M+m)\dot{x}_1^2+\frac{1}{2}m\left(2\dot{x}_1L\dot{\theta}\cos(\theta)+L^2\dot{\theta}^2\right)\end{aligned}\tag{9.3.979}$$

The potential energy will be considered taking into account only the mass at the extremity of the rod (the carriage being at the level of the ground and the mass of the rod being considered negligible):

$$E_p=mgy_2=mgL\cos(\theta) \tag{9.3.980}$$

The classical Lagrangian is then:

$$L=T-V=E_c-E_p=\frac{1}{2}(M+m)\dot{x}_1^2+m\dot{x}_1L\dot{\theta}\cos(\theta)+\frac{1}{2}mL^2\dot{\theta}^2-mgL\cos(\theta) \tag{9.3.981}$$

We will take as generalized coordinates of the system: (x_1,θ). Which are the variables we have just seen as sufficient to describe the state of the Lagrangian.

Therefore, the Lagrange equations that we have are (compared to the usual writing we have multiplied each line by -1):

$$\begin{gathered}\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{x}_1}-\frac{\partial L}{\partial x_1}=0\\ \frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{\theta}}-\frac{\partial L}{\partial \theta}=0\end{gathered} \tag{9.3.982}$$

We inject the preceding results into respectively each of the equations to obtain by already directly calculating the partial derivative:

$$\begin{aligned}&\frac{\mathrm{d}}{\mathrm{d}t}\Big((M+m)\dot{x}_1+L\dot{\theta}\cos(\theta)\Big)-0=0\\ &\frac{\mathrm{d}}{\mathrm{d}t}\Big(m\dot{x}_1L\cos(\theta)+mL^2\dot{\theta}\Big)-\Big(-m\dot{x}_1L\dot{\theta}\sin(\theta)+mgL\sin(\theta)\Big)=0\end{aligned} \tag{9.3.983}$$

and therefore:

$$\begin{aligned}&(M+m)\ddot{x}_1+L\ddot{\theta}\cos(\theta)-mL\dot{\theta}^2\sin(\theta)=0\\ &m\ddot{x}_1L\cos(\theta)+mL^2\ddot{\theta}-mgL\dot{\theta}\sin(\theta)=0\end{aligned} \tag{9.3.984}$$

Let us now write this system in matrix form:

$$\begin{bmatrix}M+m & mL\cos(\theta)\\ mL\cos(\theta) & mL^2\end{bmatrix}\begin{pmatrix}\ddot{x}_1\\ \ddot{\theta}\end{pmatrix}=\begin{bmatrix}mL\dot{\theta}^2\sin(\theta)\\ mgL\sin(\theta)\end{bmatrix} \tag{9.3.985}$$

It is a typical Lagrangian system with the square inertial matrix of dimension 2 multiplied by the acceleration vector. The term $mL\theta\dot{\theta}^2\sin(\theta)$ is a centripetal force whereas the term $mgL\sin(\theta)$ is the term of gravity.

We solve this system by inverting the square inertia matrix of dimension 2 as we have demonstrated in the section of Linear Algebra and we get:

$$\begin{aligned}\ddot{x}_1&=\frac{mg\sin(\theta)\cos(\theta)-mL\dot{\theta}^2\sin(\theta)}{m\cos^2(\theta)-(M+m)}\\ \ddot{\theta}&=\frac{-(M+m)g\sin(\theta)+mL\dot{\theta}^2\sin(\theta)\cos(\theta)}{mL\cos^2(\theta)-(M+m)L}\end{aligned} \tag{9.3.986}$$

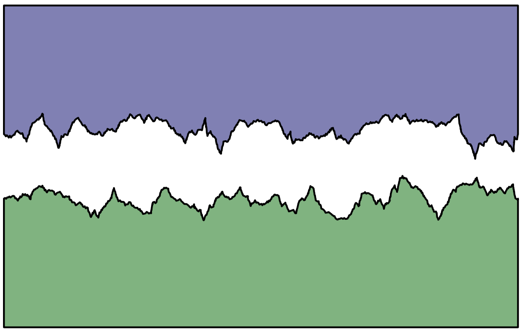
Now, the state of the system would be adequately described in the phase space by the following variables:

$$\begin{pmatrix}\dot{x}_1\\ \ddot{x}_1\\ \dot{\theta}\\ \ddot{\theta}\end{pmatrix}=\begin{bmatrix}\dot{x}_1\\ \dfrac{mg\sin(\theta)\cos(\theta)-mL\dot{\theta}^2\sin(\theta)}{m\cos^2(\theta)-(M+m)}\\ \dot{\theta}\\ \dfrac{-(M+m)g\sin(\theta)+mL\dot{\theta}^2\sin(\theta)\cos(\theta)}{mL\cos^2(\theta)-(M+m)L}\end{bmatrix} \tag{9.3.987}$$

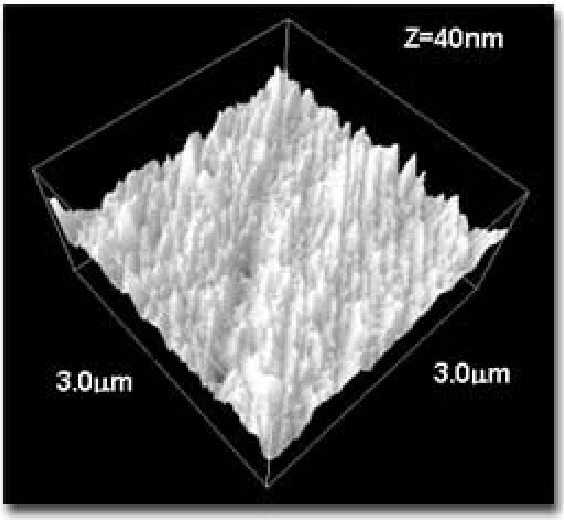
We can obviously simplify this expression by making first-order Taylor developments for small angles. What should follow is only the application of iterative numerical methods.

9.3.11 Tribology

Definition (#9.3.450): "Tribology" is the science of friction (very intuitive concept to everyone because we can feel its effects in everyday life) that occur when two contacting surfaces are moved relative to each other producing a force that opposes to the motion. This field has for purpose to study not only the conditions of friction between the bodies but also the various phenomena and physical and technical aspects in relative movement of the outer surfaces of the bodies. This field is very important in Manufacturing Technology and Aeronautics.



Below we can see a three-dimensional atomic force microscope (AFM) image of a polish mark on a piece of steel. The scan range in X and Y is 3 micrometers and the entire Z range is 40 nanometers:



Definition (#9.3.451): "Roughness" refers to the collection of small defects, peaks or hollows that form the texture of a surface of a fluid, solid or gas.

Most of these phenomena related to friction can be understood as a first approximation based on the phenomenological laws of friction set in the 118th century (holocene calendar) by Guillaume Amontons and Charles August Coulomb (but already highlighted by Leonardo Da Vinci 200 years ago) from the concept of coefficient of friction.

The analysis of a tribological system introduced 4 fundamental components:

1. The body subject to the study (this is usually a solid)
2. The support body on which acts directly the studied body (it can also be a solid, liquid or gas)
3. The intermediate material interposed between the two preceding bodies
4. And finally the environment.

Guillaume Amontons and Charles August Coulomb already observed two types of friction a priori distinct:

1. The "static friction" is the one who shows a resistance to the movement when object put on a planar surface is about the limit to slip and when we imposed to it a tensile force $\vec{F}_T$ (tangent to the plane). This opposition to the tensile force is experimentally measured as being proportional to the weight $\vec{P}$ of the object.

   But comes a limit value of the tangential tensil force from which the object starts to slip. This is what we note:

   $$\boxed{\left|\left|\vec{F}_{T,\text{lim}}\right|\right|=\mu_S\left|\left|\vec{P}\right|\right|} \tag{9.3.988}$$

   where $\vec{F}_{T,\text{lim}}$ is the tensile limit force to move the initially static object, μ_S is the "static friction coefficient" that is dimensionless and expresses the proportionality of the limit friction force with the weight $\vec{P}$ or of its normal shape relatively to the application plane. This is why this last relation is often denoted:

   $$\boxed{\left|\left|\vec{F}_{T,\text{lim}}\right|\right|=\mu_S\left|\left|\vec{N}\right|\right|} \tag{9.3.989}$$

   Remark

   In practice, the friction coefficient can be determined very easily using a simple dynamometer to measure the limiting force and a scale to measure the weight of the object being studied. For example, the static friction coefficient for steel on steel (as in railway applications) ranges from 0.15 to 0.6, while the dynamic friction coefficient ranges from 0.09 to 0.6. The Swiss Re 460 locomotive develops a maximum traction force of about 300 [kN] and has a mass of roughly 80 tons, whereas a full train convoy in Switzerland typically has a mass between 400 and 800 tons.

   We experimentally observe that contrary to the intuition, the tensile limit force is in first approximation independent of the contact surface between the object and the support (within current physical case obviously because the small the contact surface, the higher the pressure is for a same weight, then the contact surface may become plastic at high pressures...!).

   So we can now sate the both Amonton's law:

- "Amontons' first law of friction" also named "Leonardo da Vinci's law of friction" state that the friction force experienced by two dry bodies whose planar surfaces are in contact is independent of the area of contact between the bodies.
- "Amontons' second law of friction" state that the friction force (limiting value for static friction, actual value for kinetic friction) is proportional to the normal force.

In other words, if one kilo of sugar is placed on a table. To move the object, of weight $\vec{P}$ (mass multiplied by the gravitational constant), it must applied a force $\vec{F}$ parallel to the table surface. But experience shows that this object will not move until the force $\vec{F}_T$ is less than a minimum force $\vec{F}_{T,\text{lim}}$. And Amontons and Coulomb showed that this minimum force is directly proportional via a coefficient of static friction to the weight.

We can detail the approach of the above relation by imagining two surfaces having roughness in saw-tooth of an angle α and nested together:

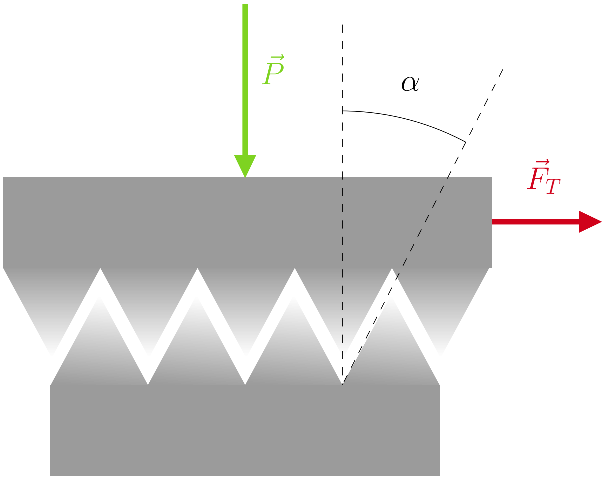


Figure 9.105: Amontons-Coulomb friction saw-tooth model

If we apply a normal force corresponding to the weight $\vec{P}$ and a horizontal force $\vec{F}_T$ we have because of the saw-tooth in the limiting case the following situation:

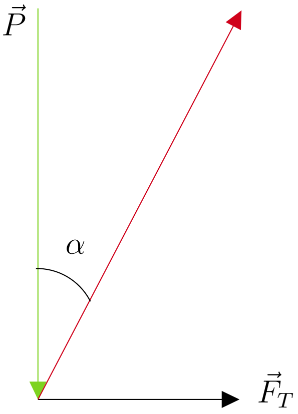

Figure 9.106: Amontons-Coulomb friction saw-tooth free-body diagram

then we see well that the movable piece will begin to move when there will be slip, that is when:

$$\boxed{\|\vec{F}_T\| = \tan(\alpha)\|\vec{P}\|} \tag{9.3.990}$$

As simplistic as it is, this approach allows to relate the (static) friction to the characteristics of roughness. Furthermore typical experimental values of the static coefficients friction of the order of 0.3 correspond surface roughness slope of the order of 15-20 degrees, which is quite compatible with the typical characteristics that can be measured for roughness of surfaces!

However, this argument is based on an implicit assumption: the perfect interlocking between the roughness of both surfaces. We speak in this case of "commensurable surfaces". This is of course not the case in general in the Nature: even at the atomic scale, two ideal surfaces are slightly different in inter-atomic distance that prevent nesting or the presence of air avoid a perfect interlocking. A slight disparity is enough to make very irregular the distribution of contact points between the two surfaces unlike the commensurable case. We speak then of "incommensurable surfaces".

2. The "dynamic friction" is the one who resists when an object placed on a plane is already slipping. This opposition to traction force is also experimentally again proportional to the weight of the object such that:

$$\boxed{\|\vec{F}_T\| = \mu_D \|\vec{P}\|} \tag{9.3.991}$$

but with the "dynamic friction coefficient" μ_D (which exists in several subfamilies: rolling friction coefficient, sliding friction coefficient, ...) - also sometimes named "kinetic friction coefficient" and denoted μ_k - which is usually much smaller than the coefficient of static friction:

$$\mu_S \gg \mu_D \tag{9.3.992}$$

So the above relation states that for two dry solid surfaces sliding against one another, the magnitude of the kinetic friction exerted through the surface is independent of the magnitude of the velocity (i.e., the speed) of the slipping of the surfaces against each other.

So the friction is not the same before our object start to slip than after he start slipping. This corresponds very well with our daily experience of friction (when moving furniture in our homes for examples).

Again, we experimentally observe that contrary to intuition, the pulling force is again independent of the contact area between the object and its support.

Thus, if we a packet of one kilo of sugar on one of its face or on its edge, assuming that at the atomic level its properties are the same everywhere, the friction force is the same (if the surface quality is the same from all sides of the packet of sugar)!

Another quite surprising fact relates to the typical values of the both coefficients of friction, which deviates relatively little $\mu_D \cong \mu_S \cong 0.3$, for very different surfaces from each other. The technologies, however, enables the design of surfaces with coefficients of friction that are much smaller ($\mu_D \cong \mu_S \cong 0.001$) or larger ($\mu_D \cong \mu_S \gg 1$).

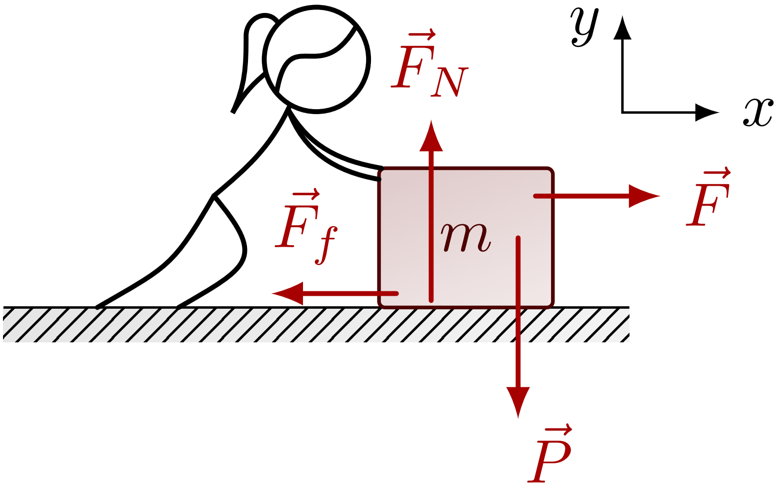
The two above relation relating pressure and pull force are name "Coulomb's friction laws", and are traditionally written:

$$\boxed{\|\vec{F}_{T,\text{lim}}\| = \mu_S \|\vec{N}\| \qquad \|\vec{F}_T\| = \mu_D \|\vec{N}\|} \tag{9.3.993}$$

and with the following notation in many contemporary high-school textbooks:

$$F_{f,\text{lim}}=\mu_S F_N=\mu_S PA \qquad F_f=\mu_D F_N=\mu_D PA \tag{9.3.994}$$

where F_N is the normal force to the support, P is the pressure (weight) and A the contact surface.



✍**Example:**

The mass of a crate is $m=32$ [kg] and the coefficient of static friction between the crate and the floor is $\mu_S=0.53$. Therefore the force necessary to start the crate moving is given as:

$$F=\mu_S mg=0.53\cdot 32\cdot 9.8\cong 166.20\,[\text{N}]$$

The largest stone ever moved by manpower alone, i.e. without the use of animals or machines, is the "Thunder Stone", an enormous boulder of granite serving as the pedestal of the famous Bronze Horseman statue of Peter the Great at St Petersburg, Russia. Before being cut into shape as the pedestal, the Thunder Stone measured 7 [m] by 14 [m] by 9 [m], and was estimated to weight around $1,500$ tonnes. It was moved 6 [km] overland to the Gulf of Finland from the marsh in Lakhta, north of the Gulf by dragging it across the frozen Russian countryside during the winter of 11768 (holocene calendar), a process taking nine months and requiring 400 men, pulling it upon a metallic sledge.

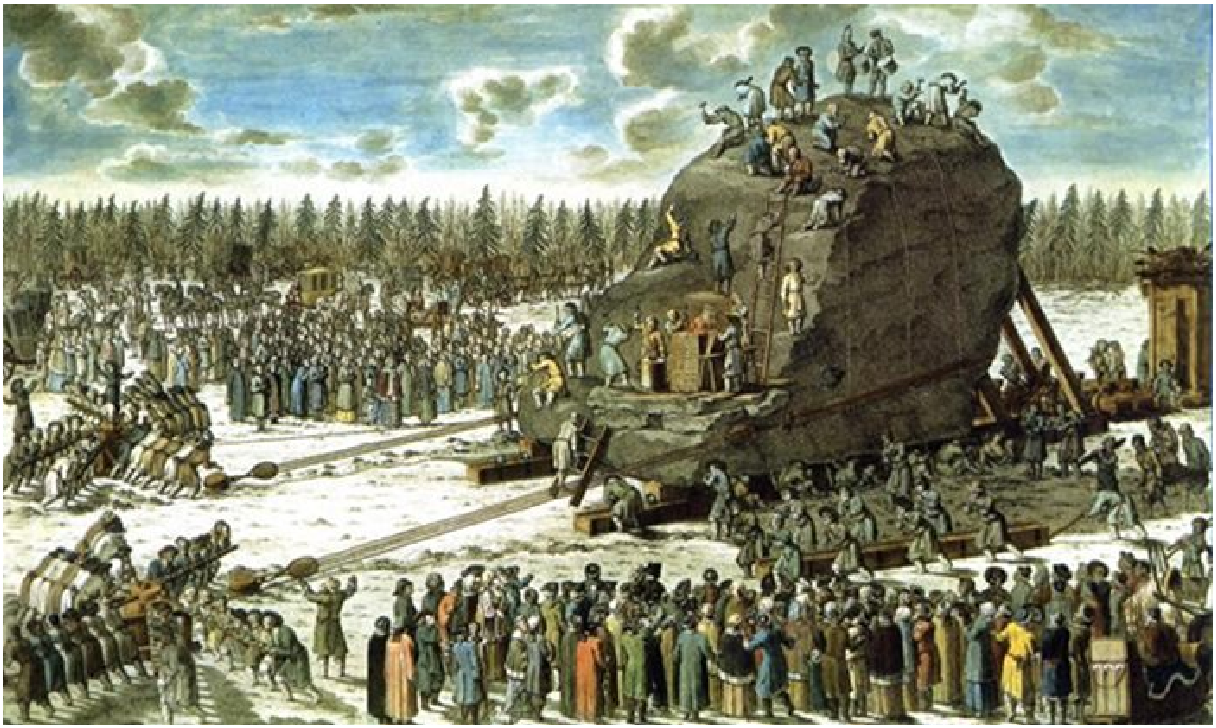


Figure 9.107: **The Transportation of the Thunder-stone in the Presence of Catherine II; Engraving by I. F. Schley of the drawing by Yury Felten, 11770**

Remarks

R1. In 12012 (holocene calendar) a Syrian man was able to move a 150 Tons train by its own force (sometimes you see in the U.S. nine locomotives pulling a lot of cars about 200 but once they are rolling they shut off a couple of engines to save fuel). In 12019 (holocence calendar) a canadian man was able to move a 189 tons airplane (c-17 globemaster III heavy transport).

R2. The reader can easily found on Internet the original video footage of a 250 tonnes excavation of the Mussolini's Monolith that was mostly done on simple wooden sledsm by human strength and with the help of other animals like cows.

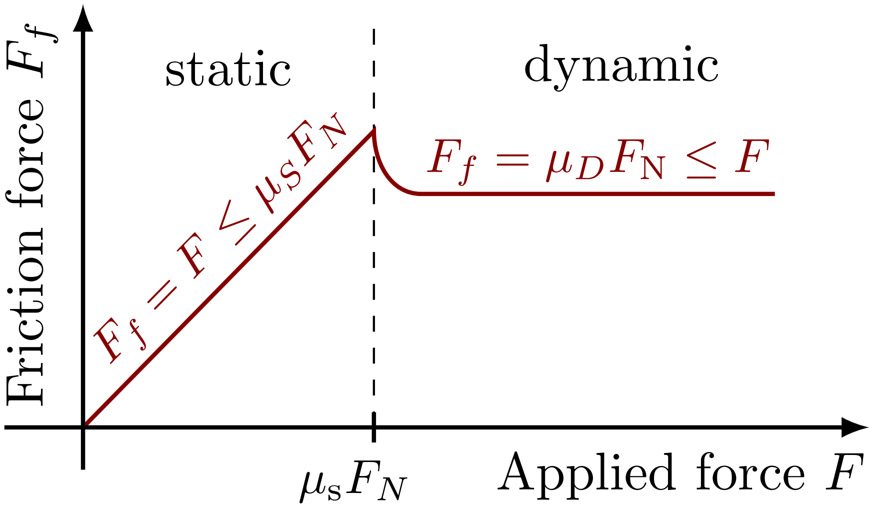

Figure 9.108: **Horizontal tribology scenario configuration (author: Izaak Neutelings)**

The naive origin of friction between two solids is therefore due to the fact that:

- Any solid is never smooth but has asperities which makes the contact surface rough (asperities overlap partially or not and cause more or less friction).
- Impurities between the two contact surfaces are often more important in terms of friction sources than the surface asperities imbrication.
- Friction is weakly dependent on the surface area because the roughness at the atomic scale is such that only a very small percentage of the total area of the two objects are actually in contact (actual contact area is therefore much smaller than the apparent contact surface) which explains that the tangential traction force is proportional to the weight because it forces the actual contact area to increase.

Remark

When two metals (pure - and clean...) of identical nature are in contact trough a smooth surface in a favourable environment (at best: in vacuum) when we can sometimes observe a "cold welding" (in vacuum it's a systematic and not just "sometimes") which is a case of extreme friction because sometimes it becomes almost impossible (or simply just impossible!) to then move one of the elements relative to the other (the result also depends slightly on the initial pressure applied to develop cold welding on the two objects of the same type). Cold welding was recognized as a general physical phenomenon of the materials science in the 11940s (holocene calendar). The reason of this unexpected behaviour is that when the atoms in contact are all of the same nature, they have no way to "know "they are present in different metal parts. When there are other atoms in the oxides and greases and other kinds of surface contaminants, the atoms "know" that they do not belong to the same object (there are widely used industrial adhesives using this principle for emergency repairs...).

Now to see a famous case of treatment of static and dynamic friction let us consider the banked curve situation!

First, the question that appears quite quickly is: What provides the centripetal force on the car for a banked curve? It is the Normal force? Gravity?.... No!!! they are both vertical forces. They have no component in the horizontal direction where we need a centripetal force.

What is it? It's friction!!!! But which friction is it? Static or Dynamic? Well maybe a bit of both and another friction, that of just sinking into the road. In our previous, discussion of friction implicitly considered just ideal rigid surfaces. But real roads do compress a bit under car weight.

In any case, friction is a reactive force that tries to prevent motion between surfaces and only turns on to try to prevent that. It's like the Normal force which only turns on if you press inward on a surface.

In the car-on-a-curve, you angle the car wheels and ideally static friction will be push exactly opposite to the car's current direction.

This static friction can be resolved into two orthogonal components. One component of frictions acts opposite to the wheel direction and the other acts perpendicular to that direction and toward a center of curvature.

Let's analyse the forces and see what relations we get.

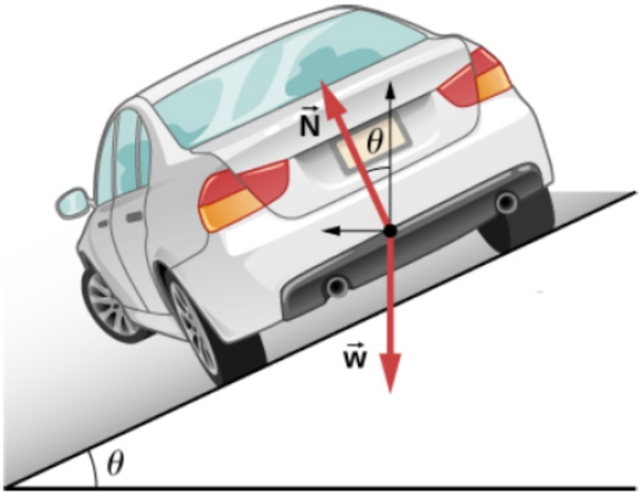

Figure 9.109: **Banked curve analysis (source: OpenStax)**

In this case, we chose the x direction to be the horizontal direction with the x axis toward the curve center. The y is vertical with up positive.

We assume a vehicle is making the turn and that we observe that it is not sliding. This is the key condition!

In the x direction, we have:

$$F_{\text{cen}} = m\frac{v^2}{r} = F_n \sin(\theta) \tag{9.3.995}$$

where F_n is the Normal force (with implicit direction Normal and outward from the surface) and θ is the angle of the normal force from the vertical and also, by geometry, the angle of the incline or banking from the horizontal. Here the x component of the normal force is providing the centripetal force.

In the y direction, we have no motion. The path is rigid, and so vehicle can't sink into the path and in any perturbation to lift off the path, gravity pulls[20] the vehicle back. So we must have balanced forces. So we have:

$$F_n \cos(\theta) = mg \tag{9.3.996}$$

where $F_n \cos(\theta)$ upward component of the Normal force and mg is the force of gravity.

Physics has given us two equations. From these we can solve for two unknowns. The most interesting variables to take to be unknowns are the normal force F_{nor} and the angle of the incline θ (which is also gives the direction of the normal force, of course).

---

[20] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

The normal force magnitude is obtained by adding the squares of the both previous relations. We get:

$$F_n = m\sqrt{\left(\frac{v^2}{r}\right)^2 + g^2} \tag{9.3.997}$$

that is obviously bigger than mg!

To get the incline angle, we divide equation 9.3.995 by equation 9.3.996 and we get:

$$\tan(\theta) = \frac{v^2}{rg} \tag{9.3.998}$$

and:

$$\boxed{\theta = \tan^{-1}\left(\frac{v^2}{rg}\right)} \tag{9.3.999}$$

This is the "banking angle formula". For a given speed and radius, the formula gives the angle one should bank a road at in order for a car to go around the curve with only the Normal force and gravity combining to give the acceleration.

Note the formula is independent of mass! This is because the Normal force is linearly dependent on mass, and so mass cancels out.

The Normal force provides all the force needed for the motion. A car at the right speed would make a properly banked curve ideally even a road were ideal frictionless ice!!!!!!!!!!!!

Note also that if v^2/r goes to infinity, θ goes to 90° and the car plane would be perpendicular to the ground.

The banking angle formula equation always seems a little mysterious. How does the Normal force know to be just strong enough? But the answer is that you have assumed that you are making the curve. Therefore the Normal force must be strong enough by the given condition. It's actually a constraint force!

If you did a banking analysis with the friction force turned on and solved for Normal force and friction force, then you would find that the friction force goes to zero for the banking angle given by the banking angle formula.

Why do civil engineers bank curves using the banking angle formula? Somewhat obviously so that the cars don't need to rely on friction to make the curve. Failure of the Normal force doesn't much happen, except maybe on mud roads. The friction force can fail even on dry roads. Water and ice and snow reduce friction substantially. Another obvious reason is that turning is much easier on a properly banked road. If you go at the specified speed, there is little need to turn the wheels at all and there is no tendency to loss of control.

Yet another reason it is easier on the road structure, the car structure, and the car contents including the passengers. The above analysis actually applies to every bit of the car and contents. If you go at the specified speed, anti-compressional forces do all the acceleration. Antishear forces (of which friction is only one) in the car and the road are never called on. Antishear forces are any force that resists layers sliding over one another including those bonded together inside solids. Calling on such forces repeatedly leads to rapid wear. It's also more comfortable for passengers to be just compressed into their seats making a curve and have no tendency to slide sideways.

Of course, if you drive at the wrong speed around a curve, antishear forces do get called on with all their discomfort, tendency to wear, and chance of failure. So you should always drive at the specified speed.

Too fast and you tend to slide outward. Too slow and you tend to slide inward. It's better to err on the too slow side, of course, because failure is probably less catastrophic. In very icy conditions what are you doing on the road anyway?

Now civil engineers can't use just one banking angle. They must go from straight, unbanked road to maximally banked road continuously. And they can't ask drivers to change speed more than once to the curve speed. So they must vary the radius of curvature to allow a continuous change from unbanked to maximally banked to unbanked again.

Now all of the analysis above is a bit idealized. There are probably many complicating effects that real engineers must include in their designs. One thing, which is probably minor in this context is that cars are not really, point masses. Forces are needed not just to make the car center of mass go round curves, but also rotate the car.

9.3.11.1 Exponential Friction

It is customary to designate as "exponential friction" the friction generated by non-toothed belts (very important case in practice) on a fixed support!

To investigate this case friction let consider the figure below where β is the winding angle of the belt around the pulley where we neglect the thickness and mass of the belt relative to the other elements and where we place ourselves at the limit of slipping and in uniform motion:

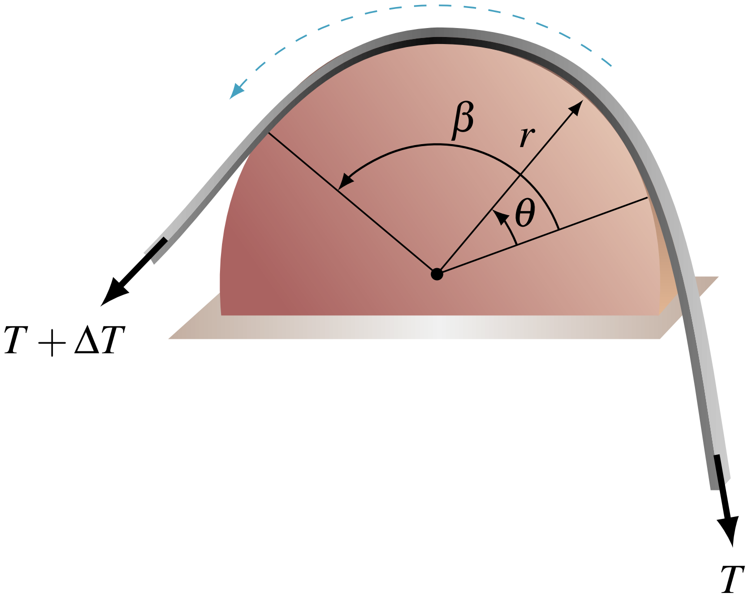

Figure 9.110: Forces between a rope and capstan

By the existence of friction there is obviously a force differential $\mathrm{d}T$ on a point of contact but this is due only to friction since we suppose a uniform rotation. Let's take a closer look to this by isolating a portion of the capstan and applying the fundamental principle of static (with subtlety...):

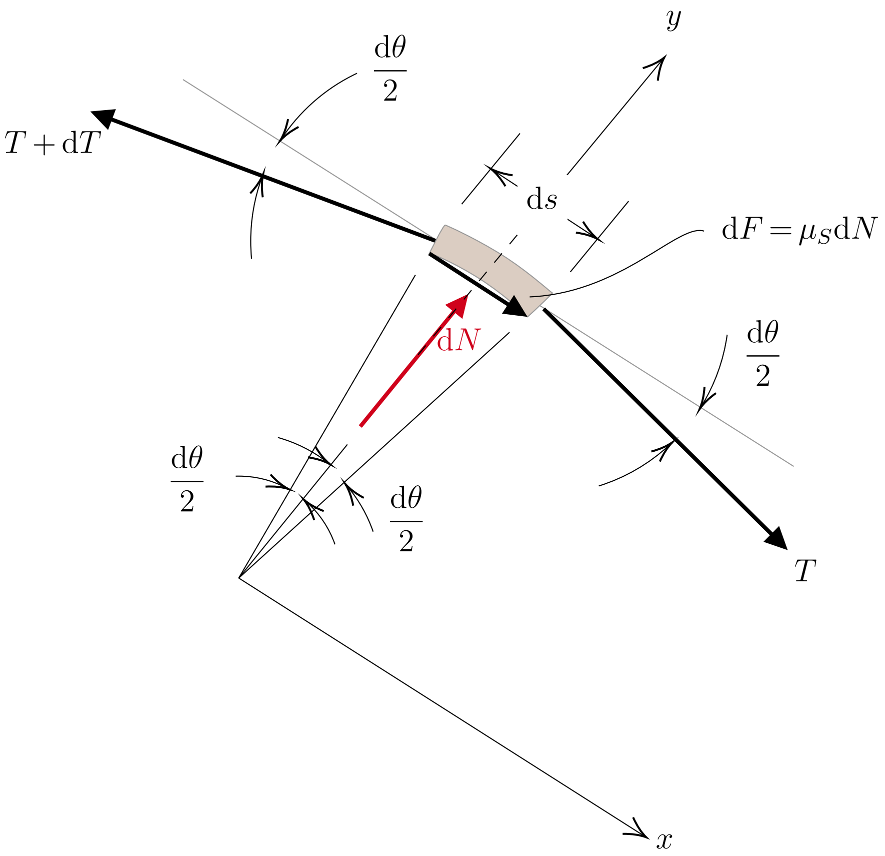

Figure 9.111: **Zoom on a differential element of the rope and capstan**

$$\begin{aligned}\sum F_x=0:\quad & T\cos\left(\frac{d\theta}{2}\right)+\mu_S dN-(T+dT)\cos\left(\frac{d\theta}{2}\right)=0\\ \sum F_y=0:\quad & dN-(T+dT)\sin\left(\frac{d\theta}{2}\right)-T\sin\left(\frac{d\theta}{2}\right)=0\end{aligned}\qquad(9.3.1000)$$

Thus after simplification:

$$\begin{aligned}\sum F_x=0:\quad & \mu_S dN-dT\cos\left(\frac{d\theta}{2}\right)=0\\ \sum F_y=0:\quad & dN-dT\sin\left(\frac{d\theta}{2}\right)-2T\sin\left(\frac{d\theta}{2}\right)=0\end{aligned}\qquad(9.3.1001)$$

and as the angle is very small, we have:

$$\cos\left(\frac{d\theta}{2}\right)\cong\cos(0)=1\qquad(9.3.1002)$$

and for the sine we use the Maclaurin development (see section Sequences and Series page 1703) for small angles:

$$\sin\left(\frac{d\theta}{2}\right)\cong\frac{d\theta}{2}\qquad(9.3.1003)$$

Then we have:

$$\begin{aligned}\sum F_x=0: &\quad \mu_S \mathrm{d}N-\mathrm{d}T=0\\ \sum F_y=0: &\quad \mathrm{d}N-\mathrm{d}T\frac{\mathrm{d}\theta}{2}-2T\frac{\mathrm{d}\theta}{2}=0\end{aligned} \qquad (9.3.1004)$$

Then after rearranging:

$$\begin{aligned}\sum F_x=0: &\quad \mu_S \mathrm{d}N=\mathrm{d}T\\ \sum F_y=0: &\quad \mathrm{d}N=T\mathrm{d}\theta\end{aligned} \qquad (9.3.1005)$$

where the first equation is already known to us as it corresponds to the usual static horizontal friction already seen earlier (Coulomb's law). We can now combine these two relations to get:

$$\mu_S \mathrm{d}\theta=\frac{\mathrm{d}T}{T} \qquad (9.3.1006)$$

By integrating it comes therefore:

$$\int\limits_0^{\beta}\mu_S \mathrm{d}\theta=\int\limits_{T_1}^{T_2}\frac{\mathrm{d}T}{T} \qquad (9.3.1007)$$

Then we have:

$$\ln\left(\frac{T_2}{T_1}\right)=\mu_S\beta \qquad (9.3.1008)$$

and finally we get the "capstan equation" or "belt friction equation", also known as "Eytelwein's formula":

$$\boxed{T_2=T_1e^{\mu_S\beta}} \qquad (9.3.1009)$$

which is very important! For example in practice with a pull force of 500 [N], it produces an actual pull force across the fixed circular support only of 250 [N] because the friction is exponential. This is why it is better to use pulleys as fixed circular supports to raise a mass!

Remark

A "holding capstan" is a ratchet device that can turn only in one direction; once a load is pulled into place in that direction, it can be held with a much smaller force. A powered capstan, also named a "winch", rotates so that the applied tension is multiplied by the friction between rope and capstan. On a tall ship a holding capstan and a powered capstan are used in tandem so that a small force can be used to raise a heavy sail and then the rope can be easily removed from the powered capstan and tied off.

In rock climbing with so-named "top-roping", a lighter person can hold (belay) a heavier person due to this effect.

Obviously because of the friction we will have:

$$T_2>T_1 \qquad (9.3.1010)$$

which obviously implies that:

$$e^{\mu_S\beta}>1 \tag{9.3.1011}$$

and therefore:

$$\mu_S\beta>0 \tag{9.3.1012}$$

For the rest, the reader is referred to go to the section of Civil Engineering where the cylindrical rollers are presented in details.

9.3.11.2 Horizontal Viscous Friction

We have seen that in a first approximation, the frictional force in the case of slipping is proportional to the weight of a body by a friction coefficient which value depends on the nature and condition of the contact surface, but independent of the contact area. We have also already mention that experience shows that in typical cases the friction force is independent of the velocity communicated to the moving body.

By lubricating by a viscous fluid two contact surfaces, the frictional force is reduced and therefore depends on the speed (this is typically the case of car tires which are viscous plastics).

Remark

For recall, the term "viscous" does not necessarily mean that it flows and it drool. This means that the behaviour law depends on the deformation speed (see section Continuum Mechanics page 3775).

Let us now consider a mobile in contact with a plane support via a fluid or viscous material. We know there will be friction and we assume that it is proportional to speed:

$$\boxed{F_f=-kv} \tag{9.3.1013}$$

where k is the "coefficient of viscous friction".

We then by applying Newton's first law:

$$F=m\frac{\mathrm{d}v}{\mathrm{d}t}=-kv \tag{9.3.1014}$$

Thus we have:

$$\frac{1}{v}\mathrm{d}v=-\frac{k}{m}\mathrm{d}t \tag{9.3.1015}$$

By integrating it comes:

$$\ln(v)-\ln(v_0)=-\frac{k}{m}t \tag{9.3.1016}$$

Therefore:

$$\ln(v)=\ln(v_0)-\frac{k}{m}t \tag{9.3.1017}$$

Taking the exponential:

$$\boxed{v = e^{\ln(v_0)} e^{-\frac{k}{m}t} = v_0 e^{-\frac{k}{m}t}} \quad (9.3.1018)$$

Thus, the speed decreases exponentially form an initial velocity to a zero asymptotic value under the assumption of proportionality of friction with speed.

It is a relation very often used in computer animations to represent objects that seem to stop naturally. You simply choose to choose the value of k.

We observe an interesting thing is that heavy moving body decelerates more slowly because of friction forces than a slight moving body!

Let us now show how to calculate the power lost by friction. We know that:

$$P = \frac{\mathrm{d}W}{\mathrm{d}t} = \frac{\mathrm{d}(Fx)}{\mathrm{d}t} = \frac{\mathrm{d}F}{\mathrm{d}t}x + \frac{\mathrm{d}x}{\mathrm{d}t}F \quad (9.3.1019)$$

if the variation in the force is negligible compared to the speed variation we have then:

$$P \cong \frac{\mathrm{d}x}{\mathrm{d}t}F = Fv \quad (9.3.1020)$$

and therefore in the case of friction (in absolute value):

$$\boxed{P \cong |F_f|v = |-kv|v = kv^2} \quad (9.3.1021)$$

Thus, the power dissipated during movement is proportional to the square of speed in the case of Coulomb friction and proportional to the square of the speed in the case of viscous friction.

9.3.11.3 Vertical Viscous Friction

Given a non-deformable solid falling vertically in a uniform gravity field. We assume that air resistance force is proportional to the speed (viscous behaviour at low speeds):

$$F_f = -kv \quad (9.3.1022)$$

and using the fundamental principle of dynamics:

$$mg - kv = m\frac{\mathrm{d}v}{\mathrm{d}t} \quad (9.3.1023)$$

Or written differently (more traditional):

$$m\frac{\mathrm{d}v}{\mathrm{d}t} + kv = mg \quad (9.3.1024)$$

The solution of this linear differential equation of the first order is (see section Integral and Differential Calculus page 1609):

$$v = \frac{mg}{k} + Ce^{-\frac{k}{m}t} \quad (9.3.1025)$$

we can detail if required (on request).

By assuming that at time zero we had a given initial velocity it comes:

$$v(t=0)=v_0=\frac{mg}{k}+C\Rightarrow C=v_0-\frac{mg}{k} \tag{9.3.1026}$$

Therefore:

$$v=\frac{mg}{k}+\left(v_0-\frac{mg}{k}\right)e^{-\frac{k}{m}t}=\frac{mg}{k}\left(1-e^{-\frac{k}{m}t}\right)+v_0e^{-\frac{k}{m}t} \tag{9.3.1027}$$

Thus we see that when time tends to infinity (long enough in other words...) then the speed approaches:

$$v\underset{t\to+\infty}{=}\frac{mg}{k} \tag{9.3.1028}$$

therefore k can be determined experimentally!

It is a relation once again very often used in computer animations to represent objects that seem to slow down at constant speed naturally by falling.

The position at any time may be found by integrating the equation for v. With $v=\mathrm{d}y/\mathrm{d}t$:

$$\int\limits_{t_0}^{t_f}\mathrm{d}y=\int\limits_{t_0}^{t_f}\left[\frac{mg}{k}\left(1-e^{-\frac{k}{m}t}\right)+v_0e^{-\frac{k}{m}t}\right]\mathrm{d}t \tag{9.3.1029}$$

The calculations that follows are obvious (but we can detail on request if needed).

9.3.11.4 Stokes' Vertical Viscous Friction

This is typically the case of the parachutist performing a free fall. We proved in the section of Continuum Mechanics that Stokes' viscous force was given by (viscous behaviour at middle and high speeds):

$$F_f=-\rho v^2L^2C(R_e)=-\rho SCv^2=-kv^2 \tag{9.3.1030}$$

when speed is subsonic (modest in other words...).

The differential equation is the same as before in the case of the presence of a uniform gravitational field with the difference that the speed is this time squared:

$$mg-kv^2=m\frac{\mathrm{d}v}{\mathrm{d}t} \tag{9.3.1031}$$

That is:

$$\frac{k}{m}v^2+\frac{\mathrm{d}v}{\mathrm{d}t}-g=0 \tag{9.3.1032}$$

but we will not try to solve this differential equation. We want only determine the limit of speed and this speed limit is reached when it does not longer varies .... (yes obviously...). So at that moment:

$$\frac{\mathrm{d}v}{\mathrm{d}t}=0 \tag{9.3.1033}$$

and the differential equation becomes:

$$\frac{k}{m}v^2-g=0 \tag{9.3.1034}$$

Therefore:

$$\boxed{v_{\text{lim}}=\sqrt{\frac{gm}{k}}=\sqrt{\frac{gm}{\rho SC}}} \tag{9.3.1035}$$

Thus, it is possible to change the falling speed limit depending on the form factor of the falling object and its apparent exhibition surface and its mass (in the above case study we have neglected the Archimedes force that applies on the parachutist and that also slows down his fall).

✍**Example:**

Let us consider a sphere of radius R, of mass density ρ, released without initial speed a liquid of mass density ρ_{liq}, of viscosity μ (see the classification of viscosity in the norm ISO 3448). The sphere is subjected to its own weight, to a viscous frictional force and to Archimedes' force. We therefore have according to Newton's first law:

$$m\frac{\mathrm{d}v}{\mathrm{d}t}=\underbrace{\frac{4}{3}\pi R^3\rho g}_{\text{attraction force}}-\underbrace{6\pi\mu Rv}_{\text{Stokes' viscous force}}-\underbrace{\frac{4}{3}R^3\rho_{\text{liq}}g}_{\text{Archimedes' force}} \tag{9.3.1036}$$

where the last two terms (viscous Stokes's force and Archimedes force) have been proved in the section of Continuum Mechanics.

Rearranging, we have:

$$m\frac{\mathrm{d}v}{\mathrm{d}t}+6\pi\mu Rv=\frac{4}{3}\pi R^3g(\rho-\rho_{\text{liq}})=\frac{4}{3}\pi R^3g\rho\left(1-\frac{\rho_{\text{liq}}}{\rho}\right) \tag{9.3.1037}$$

or also:

$$\begin{aligned}&\frac{m}{\frac{4}{3}\pi R^3\rho}\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{6\pi\mu R}{\frac{4}{3}\pi R^3\rho}v=\frac{m}{\frac{4}{3}\pi R^3}\frac{1}{\rho}\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{18\mu}{4R^2\rho}v=\rho\frac{1}{\rho}\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{9\mu}{2R^2\rho}v\\&=\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{9\mu}{2R^2\rho}v=\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g\end{aligned} \tag{9.3.1038}$$

Therefore it remains:

$$\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{9\mu}{2R^2\rho}v=\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g \tag{9.3.1039}$$

We put now:

$$\boxed{\tau=\frac{2R^2\rho}{9\mu}} \tag{9.3.1040}$$

which will be treated as a time constant. Then we have:

$$\tau\frac{\mathrm{d}v}{\mathrm{d}t}+v=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g \tag{9.3.1041}$$

But when the falling speed will become constant, we will have:

$$\frac{\mathrm{d}v}{\mathrm{d}t}=0 \tag{9.3.1042}$$

Which simplifies our previous relation and gives therefore immediately:

$$\boxed{v_{\text{lim}}=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g} \tag{9.3.1043}$$

Let us also solve the previous differential equation, beginning with that without the second member (see section Differential and Integral Calculus page 1609):

$$\frac{\mathrm{d}v}{\mathrm{d}t}+\frac{1}{\tau}v=0 \tag{9.3.1044}$$

We then saw in the section of Differential and Integral Calculus that the homogeneous solution was then given by:

$$v_h=Ce^{-\frac{1}{\tau}t} \tag{9.3.1045}$$

We can add the particular solution that is logically when t tends to infinity:

$$v_p=v_{\text{lim}}=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g \tag{9.3.1046}$$

Then we have:

$$v=v_p+v_h=v_{\text{lim}}+v_h=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g+Ce^{-\frac{1}{\tau}t} \tag{9.3.1047}$$

It remains to us to determine C which is obtained when t tends to 0 because we have then:

$$v(t=0)=v_0=0 \tag{9.3.1048}$$

Therefore:

$$v(t=0)=0=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g+Ce^{-\frac{1}{\tau}0}=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g+C\Rightarrow C=-\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g \tag{9.3.1049}$$

Then we have:

$$v=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g-\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)ge^{-\frac{1}{\tau}t} \tag{9.3.1050}$$

Finally:

$$\boxed{v=\tau\left(1-\frac{\rho_{\text{liq}}}{\rho}\right)g\left(1-e^{-\frac{1}{\tau}t}\right)} \tag{9.3.1051}$$

9.3.11.5 Stokes' Horizontal Viscous Friction

This is a first approximation where are interested for example at a distance of stop with constantly braking of a mobile without taking into account the coefficient of friction with the ground but only with the ambient air (subsonic speed always...).

We then have according to Newton's first law:

$$m\frac{\mathrm{d}v}{\mathrm{d}v}=-kv^2 \tag{9.3.1052}$$

Suppose we want to know how much time T a mobile which had an initial velocity v_0 will have decelerated to a given final speed v_f.

Then we have:

$$\mathrm{d}t=-\frac{m}{k}\frac{\mathrm{d}v}{v^2} \tag{9.3.1053}$$

Therefore:

$$T=\int\limits_0^T \mathrm{d}t=-\frac{m}{k}\int\limits_{v_0}^{v_f}\frac{1}{v^2}\mathrm{d}v=-\frac{m}{k}\left(-\frac{1}{v}\bigg|_{v_0}^{v_f}\right)=-\frac{m}{k}\left[-\frac{1}{v_f}-\left(-\frac{1}{v_0}\right)\right]=\frac{m}{k}\left(\frac{1}{v_f}-\frac{1}{v_0}\right) \tag{9.3.1054}$$

where we observe already a first problem with this model is that when stopped, the final velocity being equal to zero, it will take an infinite time to get there... but go on, we shall return to this finding.

The evolution law of the speed is determined analogously as:

$$t=-\frac{m}{k}\left[-\frac{1}{v_f}-\left(-\frac{1}{v_0}\right)\right]=\frac{m}{k}\left(\frac{1}{v_f}-\frac{1}{v_0}\right) \tag{9.3.1055}$$

Therefore:

$$t=\frac{m}{k}\frac{1}{v_f}-\frac{m}{k}\frac{1}{v_0}\Rightarrow\frac{m}{k}\frac{1}{v_f}=\frac{m}{k}\frac{1}{v_0}+t\Rightarrow\frac{1}{v_f}=\frac{1}{v_0}+\frac{k}{m}t=\frac{1}{v_0}\left(1+\frac{v_0k}{m}t\right) \tag{9.3.1056}$$

Let us put the time constant:

$$\tau=\frac{m}{v_0k} \tag{9.3.1057}$$

Therefore:

$$\frac{1}{v_f}=\frac{1}{v_0}\left(1+\frac{t}{\tau}\right) \tag{9.3.1058}$$

hence:

$$\boxed{v_f(t)=\frac{v_0}{1+\dfrac{t}{\tau}}} \tag{9.3.1059}$$

The distance travelled at the instant t, leaving the mobile slow down uniquely by the frictional forces is therefore:

$$x=\int_0^t v_f(t)\mathrm{d}t=\int_0^t \frac{v_0}{1+\dfrac{t}{\tau}}\mathrm{d}t=v_0\int_0^t \frac{1}{1+\dfrac{t}{\tau}}\mathrm{d}t=v_0\tau\ln\left(1+\frac{t}{\tau}\right) \tag{9.3.1060}$$

That is:

$$\boxed{x=\frac{m}{k}\ln\left(1+\frac{t}{\tau}\right)} \tag{9.3.1061}$$

The result is pretty but we realize that it's not correct because after an infinite time, the car will have travelled an infinite distance which is clearly unrealistic. This comes from the fact that the model is too simplistic, therefore let us improve it.

The ideal, objectively speaking, would be to take into account the viscous friction tire/ground plus the air friction. We would then have:

$$m\frac{\mathrm{d}v}{\mathrm{d}t}=-kv-k'v^2 \tag{9.3.1062}$$

but the problem with this differential equation is that it will lead us to a singularity if we continue the calculations. It is therefore not usage...

We then try with the following form:

$$m\frac{\mathrm{d}v}{\mathrm{d}t}=-m\alpha-m\beta v^2 \tag{9.3.1063}$$

which expresses that there is a friction force proportional to the weight of the vehicle which is simply the form of the second Coulomb's law:

$$F_{T,\text{lim}}=\mu_D P=\mu_D mg=m(g\mu_D)=m\alpha \tag{9.3.1064}$$

and the second term being the viscous Stokes' friction from which we have take out the mass factor included in the density being implicitly in the constant k of kv^2.

We then have simplifying the mass terms:

$$\frac{\mathrm{d}v}{\mathrm{d}t}=-\alpha-\beta v^2 \tag{9.3.1065}$$

So we already see that in this model we will lose the effect of the mass that normally has for effect to extend the travel distance before stop (in reality!) because of inertia. But let us continue anyway...

So we have to integrate:

$$-\int_0^t \mathrm{d}t=\int_{v_0}^0 \frac{\mathrm{d}v}{\alpha+\beta v^2}=\frac{1}{\beta}\int_{v_0}^0 \frac{\mathrm{d}v}{\dfrac{\alpha}{\beta}+v^2} \tag{9.3.1066}$$

We have proved in the section of Differential and Integral Calculus that:

$$\int \frac{1}{a^2+x^2} = \frac{1}{a}\arctan\left(\frac{v_0}{a}\right) \tag{9.3.1067}$$

Slightly rearranged it gives:

$$\boxed{t = \frac{1}{\sqrt{\alpha\beta}}\arctan\left(\sqrt{\frac{\beta}{\alpha}}v_0\right)} \tag{9.3.1068}$$

So now we fall on a finite time for stop... which is more reassuring result.

Let us now seek for stop distance. We use the fact that:

$$v = \frac{\mathrm{d}x}{\mathrm{d}t} \Rightarrow \mathrm{d}t = \frac{\mathrm{d}x}{v} \tag{9.3.1069}$$

gives us the possibility to write:

$$\frac{\mathrm{d}v}{\mathrm{d}t} = \frac{\mathrm{d}v}{\mathrm{d}x/v} = \frac{v\mathrm{d}v}{v\mathrm{d}x} = -\alpha - \beta v^2 \tag{9.3.1070}$$

Therefore:

$$-\mathrm{d}x = \frac{v\mathrm{d}v}{\alpha+\beta v^2} \tag{9.3.1071}$$

Which brings us to:

$$-\int_0^L \mathrm{d}x = \int_{v_0}^0 \frac{v\mathrm{d}v}{\alpha+\beta v^2} \tag{9.3.1072}$$

Which gives us first:

$$-L = \int_{v_0}^0 \frac{v\mathrm{d}v}{\alpha+\beta v^2} = \frac{1}{2\beta}\int_{v_0}^0 \frac{2\beta\mathrm{d}v}{\alpha+\beta v^2} = \frac{1}{2\beta}\ln(\alpha+\beta v^2)\bigg|_{v_0}^0 = \frac{1}{2\beta}\left[\ln(\alpha) - \ln(\alpha+\beta v_0^2)\right] \tag{9.3.1073}$$

So we have our final result. Better than the last result but however independent of the mass ... but in the meantime it's better than nothing...

Remark

With a dry braking the front axle of a small car (Mercedes Benz Class A 190 Elegance) has a braking force typically of the order of 2.8 [kN].

9.3.11.6 Friction's Heat Factor

The sliding friction intervening between two bodies in contact results in a loss of mechanical energy almost entirely converted into heat energy Q (see section Thermodynamics page 3599). The problem of conversion of friction energy into heat is always very complex and requires detailed studies but is of major importance in the industry.

For simplicity, let assume that the friction component remains constant, applied to the center of gravity of the friction surface, and the speed of the body is linear and constant. The work done by the friction force, for a finite displacement is then:

$$W_f = F_f \Delta L \tag{9.3.1074}$$

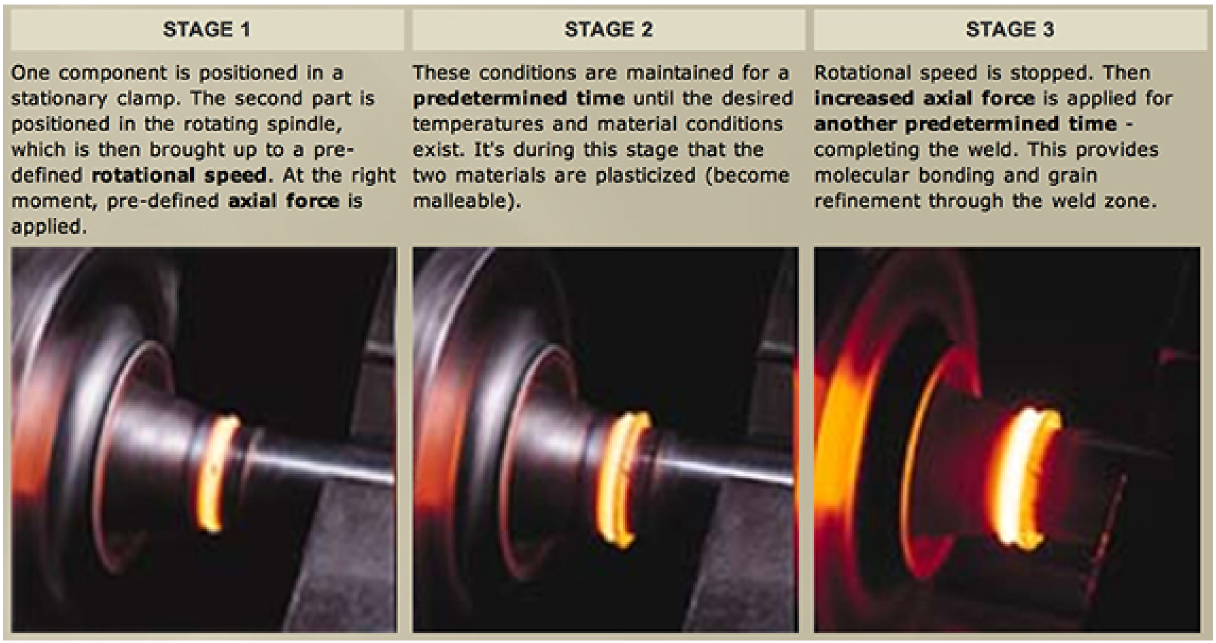
Assuming this mechanical work completely transformed into thermal energy, the quantity of heat produced must be evacuated out of the friction surfaces. This is a fundamental problem in the mechanisms with high heat release such as brakes, clutches, gear transmissions and worm gear and especially plain bearings. The released heat output is then calculated by:

$$\dot{Q} = \frac{F_f \Delta L}{\Delta t} = F_f \frac{\Delta L}{\Delta t} = F_f v \tag{9.3.1075}$$

We just have to divide by the total contact area to the heating power per unit area. Then, in the special case of Coulomb's dynamic friction, we have this last relation that will be written:

$$\boxed{\dot{Q} = F_f v = \mu_D P A v} \tag{9.3.1076}$$

The heat output is proportional to the friction coefficient μ_D and the product of the mean pressure P by the sliding velocity v and the contact area A. This control method of heating is obviously a rough first approach because the coefficient of friction, the pressure and the sliding speed are only part of the factors influencing the temperature of operation of a mechanism.



STAGE 1	STAGE 2	STAGE 3
One component is positioned in a stationary clamp. The second part is positioned in the rotating spindle, which is then brought up to a pre-defined **rotational speed.** At the right moment, pre-defined **axial force** is applied.	These conditions are maintained for a **predetermined time** until the desired temperatures and material conditions exist. It's during this stage that the two materials are plasticized (become malleable).	Rotational speed is stopped. Then **increased axial force** is applied for **another predetermined time** - completing the weld. This provides molecular bonding and grain refinement through the weld zone.

9.4. Wave Mechanics

HERE we focus on the study of mathematical properties of vibrating strings that we can also by extension and in a wish of generality assimilate to the immaterial cases of the important concept of "waves". This study is very important because we need some of the results that will be proven here in the section of Thermodynamics, Quantum physics, Astrophysics, Electrodynamics, Acoustics and String theory (to mention only the most important one).

Definitions (#9.4.452):

D1. A "wave" is a transport of energy without transporting material. It is embodied in the propagation of a disturbance of a medium, hence the name "travelling wave". The speed with which the wave progresses depends obviously on the physical properties of the medium.

D2. In the case where the disturbance of the medium (deformation of the wave) is perpendicular to the wave propagation direction, we speak about "transverse wave" or "transverse disturbance" (typical of waves in string for example).

D3. In the case where the disturbance of the medium is parallel to the wave propagation direction, we speak about "longitudinal wave" or "longitudinal disturbance " (typical of springs).

9.4.1 Wave Function

Given a disturbance $y=f(x)$ in a given region of space. If we replace x by $x-b$ we define, in the same region, a disturbance $f(x-b)$ identical to $f(x)$ but translated a distance b in the direction of positive X (to the right if we adopt the conventional representation seen in the section of Functional Analysis).

If t represent a time and if we put $b=vt$, then v can denote the translational speed of the disturbance.

So we name "wave function", the mathematical relation:

$$\boxed{f(x\pm vt)} \tag{9.4.1}$$

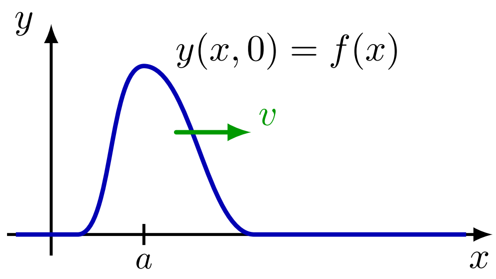
that describes the progress of a disturbance $y(x,t)$ in the space:

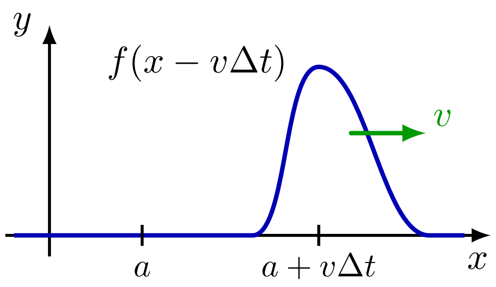
- $y(x,t)=f(x-vt)$ describing a wave that progresses in the direction of $+X$
- $y(x,t)=f(x+vt)$ describing a wave that progresses in the direction of $-X$

v is by definition named "wave phase velocity" and vt the "phase shift". It is constant in a homogeneous medium. The "amplitude of the wave" is the maximum value of the perturbation:

$$y_{\max}=\hat{y} \tag{9.4.2}$$

In the absence of damping, it will retain the same value in each of the points x where the wave passes.





9.4.2 Wave Equation

Theorem 9.9. Without getting into too technical considerations, we will say that every function f whose argument is $x\pm vt$ has the property:

Proof 9.9.1.

$$\begin{gathered}\frac{\partial}{\partial x}f(x-vt)=1\cdot f'(x-vt)\Rightarrow f'(x-vt)=\frac{\partial}{\partial x}f(x-vt)\\ \frac{\partial}{\partial t}f(x-vt)=-v\cdot f'(x-vt)\Rightarrow f'(x-vt)=-\frac{1}{v}\frac{\partial}{\partial t}f(x-vt)\end{gathered} \tag{9.4.3}$$

and therefore the equality follows immediately (this is simply the application of composed derivative as proved in the section of Differential and Integral Calculus).

■ Q.E.D.

Following a request from a reader who did not find this proof very clear, let us make an example. Consider the following function:

$$f(x-vt)=(x-vt)^2 \tag{9.4.4}$$

and therefore:

$$\begin{gathered}\frac{\partial}{\partial x}f(x-vt)=\frac{\partial}{\partial x}(x-vt)^2=\underbrace{1}_{=\frac{\partial}{\partial x}(x-vt)}\cdot\underbrace{2(x-vt)}_{=f'}=2x-vt\\ \frac{\partial}{\partial t}f(x-vt)=\frac{\partial}{\partial t}(x-vt)^2=\underbrace{-v}_{=\frac{\partial}{\partial t}(x-vt)}\cdot\underbrace{2(x-vt)}_{=f'}=-2xv+v^2t\end{gathered} \tag{9.4.5}$$

Returning to the general case, we derive a second time, we obtain another form of the wave equation that we also meet frequently in practice and in the books:

$$\begin{gathered}\frac{\partial^2}{\partial x^2}f(x-vt)=1\cdot\frac{\partial}{\partial x}f'(x-vt)=1\cdot 1\cdot f''(x-vt)\Rightarrow f''(x-vt)=\frac{\partial x^2}{\partial x^2}f(x-vt)\\ \frac{\partial^2}{\partial t^2}f(x-vt)=-v\cdot\frac{\partial}{\partial t}f'(x-vt)=v^2 f''(x-vt)\Rightarrow f''(x-vt)=\frac{1}{v^2}\frac{\partial^2}{\partial t^2}f(x-vt)\end{gathered} \tag{9.4.6}$$

Which brings us to write one of the most important relations in physics named the "wave equation", "propagation equation" or "d'Alembert's equation" and that we see again many times in other sections of this textbook (Electrodynamics, Wave Quantum Physics, General Relativity, Acoustic):

$$\boxed{\frac{\partial x^2}{\partial x^2}f(x\pm vt)=\pm\frac{1}{v^2}\frac{\partial^2}{\partial t^2}f(x\pm vt)} \tag{9.4.7}$$

Remarks

R1. Don't forget (see section Differential and Integral Calculus page 1605) that the sum of the solutions to a differential equation is also a solution of the differential equation!

R2. When two or more waves propagate in a medium, the wave function that results is the algebraic sum of each wave of wave functions. We say then that the waves "interfere" and we name the phenomenon "superposition wave principle" (see further below for mathematical details).

Consider now a string of length L attached by one of its ends to a fixed terminal. Now suppose that a disturbance propagate into the string. When the disturbance reaches the end (terminal), we observe that it changes in sign and that the speed is reversed: the wave is then subject to a reflection with inversion.

To describe the phenomenon, we must impose at the terminal:

$$y(L,t)=0 \qquad \forall t \tag{9.4.8}$$

But any wave function of the form $f(x\pm vt)$, which progresses to the termination, can not verify the above condition:

$$f(x-vt)_{x=L}=f(L-vt)=0 \tag{9.4.9}$$

for all time values t.

The trick is to replace it with another wave function $y(x,t)$ whose shape is similar to f at large distance from the source of the interference, and which is zero at the point of termination for all time values t. For this, we can imagine at the point of termination, a mirror which gives an image of the string of the same length in which we invent a virtual wave:

$$f(2L-(x\pm vt))=f((2L-x)-vt) \tag{9.4.10}$$

symmetrical to $f(x-vt)$, but of opposite sign.

We decide therefore:

- That the two waves progress toward each other to cancel at the endpoint
- Any part of the real wave that pass through the endpoint becomes virtual
- Any part of the virtual wave which enters the string becomes real

At their intersection, the two waves achieve a destructive interference at the endpoint. The algebraic sum of these two wave functions is also a wave function:

$$\boxed{y(x,t)=f(x-vt)-f(2L-(x+vt))} \tag{9.4.11}$$

which has the desired property at $x=L$ for any t:

$$y(L,t)=f(L-vt)-f(2L-(L+vt))=0 \tag{9.4.12}$$

If we now consider a free termination, without friction with its fixed point, we find ourselves in a similar case to the previous one except that the interference is constructive at the endpoint rather than destructive so that the wave function will be written:

$$y(x,t)=f(x-vt)+f(2L-(x+vt)) \tag{9.4.13}$$

Remarks

R1. When the wave arrives on a free or fixed termination, the energy carried is fully returned back.

R2. When the termination is not exactly adapted, only a portion of the energy is absorbed by it, the rest is reflected.

9.4.3 Type of Waves

In theoretical physics (and in practice), we often restrict the study of certain phenomena to particular cases of waves. Primarily, we recognize three of them that we will briefly but carefully develop here:

9.4.3.1 Periodic Waves

If an event produces a wave does that carry only single disturbance produced at a given point, there are many disturbances which are capable to excite a medium in a repeatedly (periodic) way.

The spatial point of the source is then subjected to the same periodic disturbance. The duration of a complete cycle is made identically to our study of pendulum, the "period T".

If the disturbance can propagate as a wave, at speed v, it is described by the wave function that we know:

$$y=f(x,t)=f(x-vt) \tag{9.4.14}$$

At each point of the disturbed system, the periodic wave imposes a "temporal periodicity" of the disturbance which requires us to write:

$$y(x=c^{te})=f(x,t+n_1T)=f(x,t) \qquad \forall x,n_1\in\mathbb{Z} \tag{9.4.15}$$

After several cycles (periods) of disturbances from the source, more disturbances are distributed in space. The distance between two successive disturbances is named the "wavelength λ".

The "spatial periodicity" also requires that:

$$y(t=c^{te})=f(x+n_2\lambda,t)=f(x,t) \qquad \forall t,n_2\in\mathbb{Z} \tag{9.4.16}$$

Therefore, in the case of a periodic wave, λ is the path travelled by the wave during the time T:

$$\boxed{\lambda=vT\Leftrightarrow v=\frac{\lambda}{T}} \tag{9.4.17}$$

Theorem 9.10. If a wave function is periodic in time, it is also in the space, provided that the pulse does not deform as it progresses.

Proof 9.10.1.

$$\begin{aligned}f(x,t)=f(x,t+n_1T)&=f(x-v(t+n_1T))=f(x-vt-n_1vT)=f(x-n_1\lambda-vt)\\&=f(x-n_1\lambda,t)\end{aligned} \tag{9.4.18}$$

By putting $n_2=-n_1=n$ we have:

$$f(x,t+n_1T)=f(x-n_1\lambda,t) \tag{9.4.19}$$

that becomes:

$$f(x,t+nT)=f(x+n\lambda,t) \tag{9.4.20}$$

■ Q.E.D.

9.4.3.2 Harmonic Waves

For these waves, the wave function solution of the d'Alembert's equation is a trigonometric function of the sine or cosine type (or sum of them):

$$y(x,t)=f(x-vt)=\hat{y}\sin(k(x-vt)) \quad \text{or} \quad y(x,t)=f(x-vt)=\hat{y}\cos(k(x-vt)) \tag{9.4.21}$$

The presence of k that represents the number of waves or cycles per unit distance, named "wave number" (sometimes also written "wavenumber" in some textbooks) or "propagation number", is required for two reasons:

- k is expressed in $[\text{m}^{-1}]$
- the value of k must ensure the periodicity of the wave function:

1. Angular periodicity of the mathematical function:

$$\sin(k(x-vt)\pm 2\pi)=\sin(k(x-vt)) \tag{9.4.22}$$

2. Spatial periodicity of the wave function:

$$\sin(k(x\pm\lambda)-vt)=\sin(k(x-vt)) \tag{9.4.23}$$

By equating these two expressions:

$$k(x-vt)\pm 2\pi=k((x\pm\lambda)-vt)=k(x-vt)\pm k\lambda \tag{9.4.24}$$

which implies:

$$\boxed{k=\frac{2\pi}{\lambda}} \tag{9.4.25}$$

Let us introduce:

$$\lambda=vT \tag{9.4.26}$$

in the expression of k:

$$\boxed{kv=\frac{2\pi}{T}=2\pi f=\omega} \tag{9.4.27}$$

hence another important relation, the explicit relation of the "phase velocity":

$$\boxed{v=\frac{\omega}{k}} \tag{9.4.28}$$

$$\begin{tikzcd}
 & \underset{\text{linear wavenumber}}{\tilde{\nu}} \arrow[rr, "x\cdot\tau"] \arrow[dl, "x\cdot v_p"'] \arrow[dd, dotted, leftrightarrow, "\frac{1}{x}"] & & \underset{\text{angular wavenumber}}{k} \arrow[dl, "x\cdot v_p"] \arrow[dd, leftrightarrow, "\frac{1}{x}"] \\
\underset{\text{linear frequency}}{f} \arrow[rr, "x\cdot\tau"] \arrow[dd, leftrightarrow, "\frac{1}{x}"'] & & \underset{\text{angular frequency}}{\omega} \arrow[dd, leftrightarrow, "\frac{1}{x}"] & \\
 & \underset{\text{linear wavelength}}{\lambda} \arrow[rr, dotted, "x/\tau"] \arrow[dl, dotted, "x/v_p"] & & \underset{\text{angular wavelength}}{\lambdabar} \arrow[dl, "x/v_p"] \\
\underset{\text{linear period}}{T} \arrow[rr, "x/\tau"] & & \underset{\text{angular period}}{?} &
\end{tikzcd}$$

v_p = wave speed (phase velocity)
$\tau = 2\pi$

Figure 9.113: **Commutative diagram of harmonic wave properties (source: Wikipedia, author: Waldir)**

The wave function of the harmonic wave can thus be written as:

$$\begin{aligned} y(x,t)&=\hat{y}\sin(kx-\omega t) \quad \text{or} \quad y(x,t)=\hat{y}\sin\left[2\pi\left(\frac{x}{\lambda}-\frac{t}{T}\right)\right] \qquad \text{progressive along } +X \\ y(x,t)&=\hat{y}\sin(kx+\omega t) \quad \text{or} \quad y(x,t)=\hat{y}\sin\left[2\pi\left(\frac{x}{\lambda}+\frac{t}{T}\right)\right] \qquad \text{progressive along } -X \end{aligned} \tag{9.4.29}$$

9.4.3.2.1 Phase velocity and Group velocity

According to what we have just seen above, the phase velocity of a monochromatic wave is equal to the ratio between its pulsation and its wave number (norm of the wave vector).

Let us consider now the simple case consisting of a wave of the superposition of two different pulsations and unit amplitude:

$$\phi(x,t)=\cos(\omega_1 t-k_1 x)+\cos(\omega_2 t-k_x) \tag{9.4.30}$$

Using trigonometric identities (Simpson's formula) we have:

$$\phi(x,t)=2\cos\left(\frac{\omega_2+\omega_1}{2}t-\frac{k_2+k_1}{2}x\right)\cos\left(\frac{\omega_2-\omega_1}{2}t-\frac{k_2-k_1}{2}x\right) \tag{9.4.31}$$

Thus, the wave in question consists of the product of two terms:

- The first term is a monochromatic wave whose velocity phase is:

  $$v_\phi=\frac{\omega_2+\omega_1}{k_2+k_1} \tag{9.4.32}$$

- The second therm is another monochromatic wave whose velocity phase is:

  $$v_\phi=\frac{\omega_2-\omega_1}{k_2-k_1}=\frac{\Delta\omega}{\Delta k} \tag{9.4.33}$$

  This term intervenes as amplitude modulator of the first term.

There is thus a beat phenomenon (i.e. "beating") where a sine wave is modulated in amplitude modulated by a lower pulse sinusoid. The group velocity is then by definition:

$$v_g=\frac{\Delta\omega}{\Delta k} \tag{9.4.34}$$

Finally:

$$\boxed{v_\phi=\frac{\omega}{k} \qquad v_g=\frac{\Delta\omega}{\Delta k}} \tag{9.4.35}$$

Here is an example of a large beating:

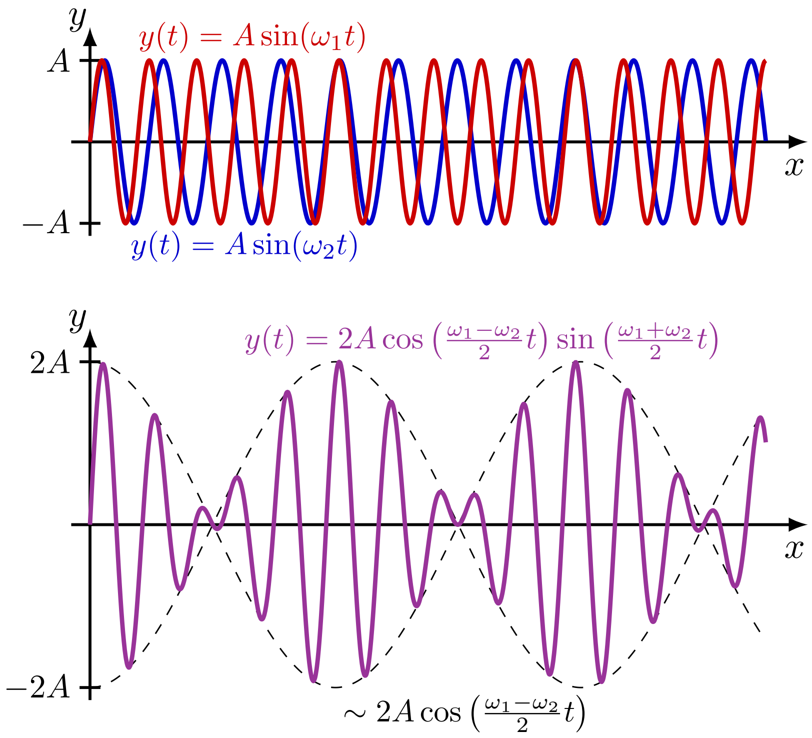


Figure 9.114: Beating with large difference in wavelength (author: Izaak Neutelings)

and with a small beating:

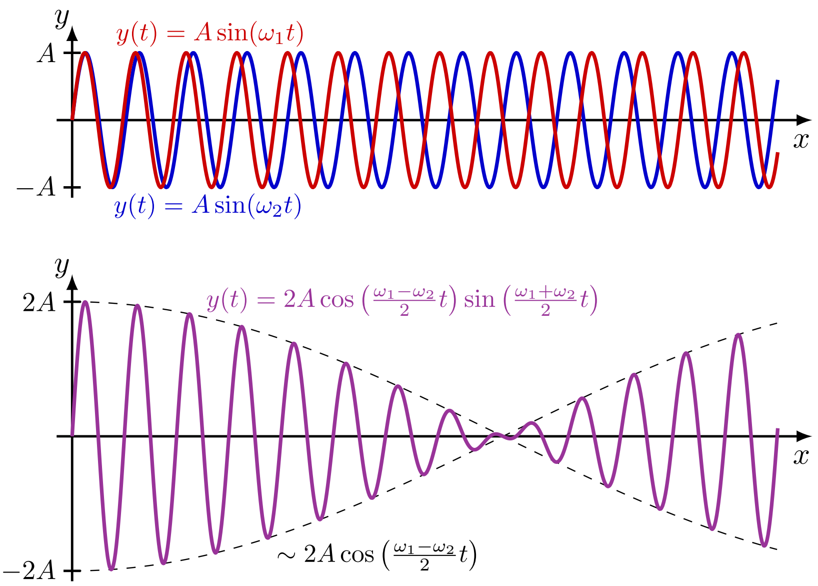

Figure 9.115: Beating small large difference in wavelength (author: Izaak Neutelings)

We can illustrate the both velocities with an animation in Maple™ 4.00b:

```
>restart:with(plots):
>lambda[0]:=1; T[0]:=1; k[0]:=2*Pi/lambda[0]; w[0]:=2*Pi/T[0];
>delta_k:=k[0]/8:  k[1]:=k[0]-delta_k; k[2]:=k[0]+delta_k;
```

```
delta_w:=w[0]/10:  w[1]:=w[0]-delta_w; w[2]:=w[0]+delta_w;
>P1:=animate(cos(k[1]*x-w[1]*t)+cos(k[2]*x-w[2]*t), x=0..1*2*Pi/delta_k,
t=0..2*Pi/delta_w, numpoints=200, frames=15, color=red):
>P2:=animate(2*cos(-1/2*k[1]*x+1/2*w[1]*t+1/2*k[2]*x-1/2*w[2]*t),
-2*cos(-1/2*k[1]*x+1/2*w[1]*t+1/2*k[2]*x-1/2*w[2]*t),
x=0..1*2*Pi/delta_k, t=0..2*Pi/delta_w, numpoints=100, frames=15,
color=blue):
>display(P1,P2);
```

Which gives visually:

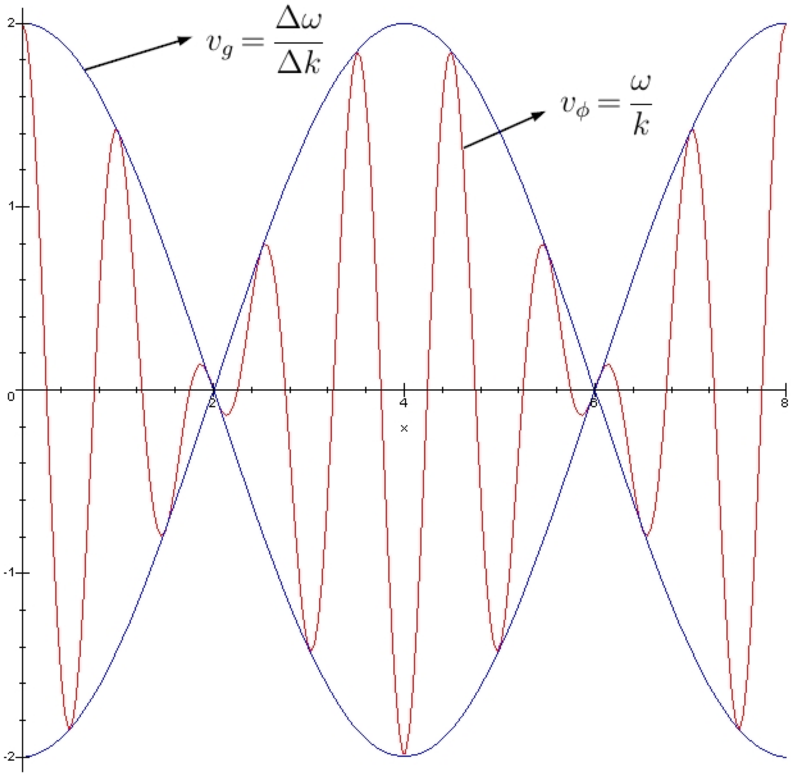

Figure 9.116: **Group and Phase velocities difference**

9.4.3.3 Stationary Waves

Let us imagine a string excited in a harmonic way. Rather than adapting its end to extract the energy of the string, let us assume that this end is fixed. The wave is therefore reflected!!!

A new wave function must be define to describe the superposition of the incoming wave:

$$y_1(x,t)=\hat{y}\sin(kx-\omega t) \tag{9.4.36}$$

and of the reflected wave (symmetric and of opposite sign):

$$y_2(x,t)=\hat{y}\sin(k(2L-x)-\omega t) \tag{9.4.37}$$

by analogy with the result that w have found during our study of the ends of strings:

$$y(x,t)=f(k(2L-x)-vt) \tag{9.4.38}$$

The following trigonometric identity proved in the section of Trigonometry:

$$\sin(p)-\sin(q)=2\sin\left(\frac{p-q}{2}\right)\cos\left(\frac{p+q}{2}\right) \tag{9.4.39}$$

gives us:

$$\boxed{y(x,t)=y_1(x,t)+y_2(x,t)=2\hat{y}\sin(k(x-L))\cos(kL-\omega t)} \tag{9.4.40}$$

This is not a progressive wave as x and t does combine anymore like $(x-vt)$. Some points of the string never move. They satisfy:

$$\sin(k(x-L))=0\Rightarrow k(x-L)=\pm n\pi\Rightarrow\frac{2\pi}{\lambda}(x-L)=\pm n\pi \tag{9.4.41}$$

and are located therefore on:

$$\boxed{x=L\pm n\frac{\lambda}{2}} \tag{9.4.42}$$

For obvious reasons, we will keep only the values of n for which $x<L$.

Each of these points is named a "vibration node".

We observe in such a system, vibration zones, of length $\lambda/2$, in which the string vibrates transversely in an height region of $4\hat{y}$ (two up, two down).

Remark

The points at which the amplitude of vibration is maximum are named sometimes the "antinodes of the vibration".

Since $\sin(k(x-L))=1$, the antinodes are apart of $\lambda/2$ and located at $\lambda/4$ of the nodes.

If we now impose a fixed termination on both ends of a vibrating string, we end up with a configuration named "resonance system".

Most often, we do not observe much until we find the excitation frequency vibrations that places nodes on the two fixed endpoints.

Therefore for a string of length L:

$$x=0=L\pm n\frac{\lambda}{2} \tag{9.4.43}$$

involves:

$$L=n\frac{\lambda}{2}\Leftrightarrow\lambda=\frac{2L}{n} \tag{9.4.44}$$

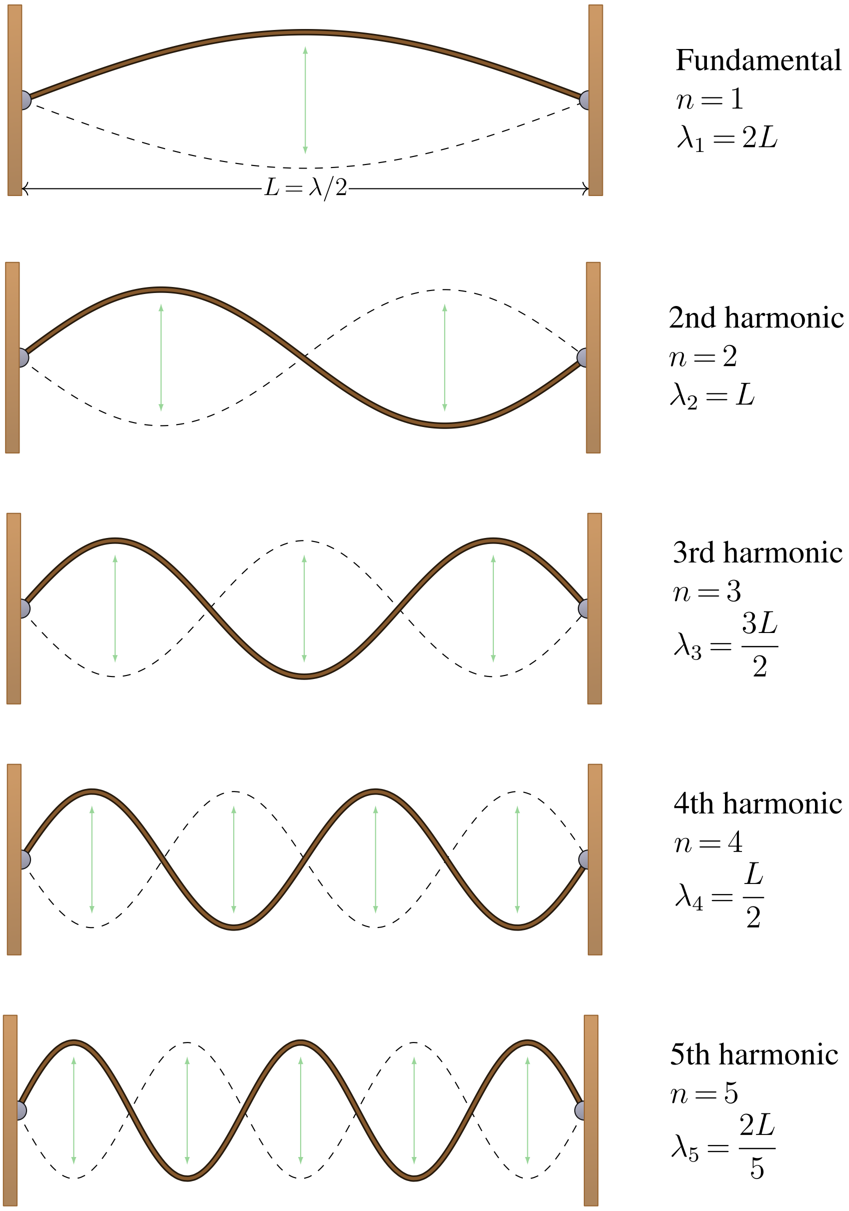
The string is then the seat of a standing wave whose vibration amplitude is considerably greater than the excitation amplitude (four times)!

We then say that the string came into "resonance" with the exciter.

The relation:

$$\boxed{\lambda=\frac{2L}{n}} \qquad (9.4.45)$$

shows that there are several possible wavelengths whose largest corresponding to $n=1$ and is named the "fundamental wavelength" or "fundamental harmonic" and is obviously equal to $\lambda=2L$:



$L=\lambda/2$
Fundamental
$n=1$
$\lambda_1=2L$
2nd harmonic
$n=2$
$\lambda_2=L$
3rd harmonic
$n=3$
$\lambda_3=\frac{3L}{2}$
4th harmonic
$n=4$
$\lambda_4=\frac{L}{2}$
5th harmonic
$n=5$
$\lambda_5=\frac{2L}{5}$

Figure 9.117: **Double fixed standing wave (author: Izaak Neutelings)**

9.4.3.4 Vibration Modes in a Stretched String

We have seen how a wave can move in a string. Let us show now why this is possible and establish the relation $y(x,t)$, giving the shape of the string over time.

Given a wire of diameter $\varnothing$, of length L and mass m, the linear density of the string (assumed constant along it) is then:

$$\rho_l = \frac{m}{L} = \frac{\Delta m}{\Delta L} = \frac{\Delta m}{\Delta x} \qquad (9.4.46)$$

By a small shock, we generate a small transversal perturbation (so we do deform the string and maintain its linear density constant). Let us isolate, in the disturbed area, a string element of length ΔL.

The approximations are the following:

1. Each element of the string may be cut infinitesimally so as to be almost parallel to the x-axis. The angles θ_P, θ_Q are considered small.
2. The string is considered as deformable but non-extensible therefore the norm of the forces in the string is constant at any point regardless of the deformation.

For the rest of the reasoning, we use the figure below:

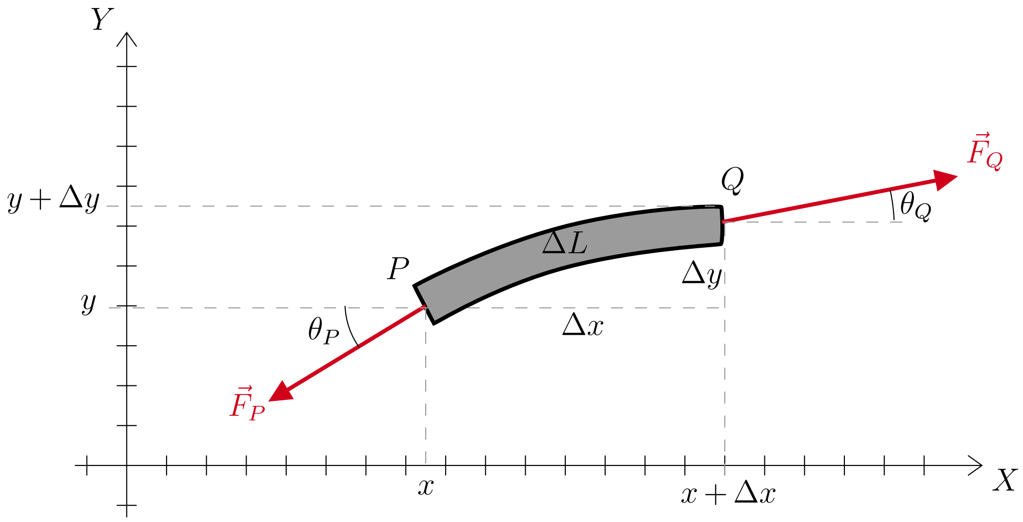


Figure 9.118: **Stretched string scheme**

If the angles are small, the balance of forces gives:

$$\sum F_x = F\cos(\theta_Q) - (F\cos(\theta_P)) - F(\cos(\theta_Q) - \cos(\theta_P)) \cong 0 \qquad (9.4.47)$$

which means that there is no displacement following the x-axis:

$$\sum F_y = F\sin(\theta_Q) - (F\sin(\theta_P)) = F(\sin(\theta_Q) - \sin(\theta_P)) \qquad (9.4.48)$$

If the angles are really small, we have the first term of the Taylor development of $\sin(x)$ and $\tan(x)$ (see section Sequences and Series page 1703) which gives:

$$\sin(x) \cong x \cong \tan(x) \tag{9.4.49}$$

Therefore:

$$\sum F_y = F(\sin(\theta_Q) - \sin(\theta_P)) \cong F(\tan(\theta_Q) - \tan(\theta_P)) \tag{9.4.50}$$

is the acceleration following the y-axis for small angles.

Newton's law applied to the mass $\Delta m = \rho_l \Delta x$ gives (we consider that each point of the mass moves only according to the y-axis since there is no elongation and as we are in the assumption of a transverse excitation):

$$\sum F_y = \Delta m a_y = \rho_l \Delta x \frac{\partial^2 y}{\partial t^2} \tag{9.4.51}$$

The tangents are given by the partial derivatives of the function $y(x)$:

$$\sum F_y = F(\tan(\theta_Q) - \tan(\theta_P)) = F\left(\left.\frac{\partial y}{\partial x}\right|_Q - \left.\frac{\partial y}{\partial x}\right|_P\right) \tag{9.4.52}$$

Which is equalized with the prior-previous relation:

$$\rho_l \Delta x \frac{\partial^2 y}{\partial t^2} = F\left(\left.\frac{\partial y}{\partial x}\right|_Q - \left.\frac{\partial y}{\partial x}\right|_P\right) \tag{9.4.53}$$

and therefore:

$$\frac{\partial^2 y}{\partial t^2} = \frac{F}{\rho_l} \frac{\left(\left.\frac{\partial y}{\partial x}\right|_Q - \left.\frac{\partial y}{\partial x}\right|_P\right)}{\Delta x} \tag{9.4.54}$$

If $\Delta x \to 0$, the two tangents tend to the same value, but the fraction of the right-hand side tends to a finite value:

$$\lim_{\Delta x \to 0} \frac{\left(\left.\frac{\partial y}{\partial x}\right|_Q - \left.\frac{\partial y}{\partial x}\right|_P\right)}{\Delta x} = \frac{\partial y^2}{\partial x^2} \tag{9.4.55}$$

It follows the differential equation:

$$\lim_{\Delta x \to 0} \frac{\left(\left.\frac{\partial y}{\partial x}\right|_Q - \left.\frac{\partial y}{\partial x}\right|_P\right)}{\Delta x} = \frac{\partial y^2}{\partial x^2} \tag{9.4.56}$$

$$\frac{\partial^2 y}{\partial t^2} = \frac{F}{\rho_l} \frac{\partial^2 y}{\partial x^2} \tag{9.4.57}$$

The latter relation is usually written as follows:

$$\boxed{\frac{\partial^2 y}{\partial x^2} - \frac{\rho_l}{F} \frac{\partial^2 y}{\partial t} = 0} \tag{9.4.58}$$

and is named "equation of vibrating strings".

Remark

In some books, the linear density is denoted by μ_0 and the tension force in the string by T_0 which gives:

$$\frac{\partial^2 y}{\partial x^2}-\frac{\mu_0}{T_0}\frac{\partial^2 y}{\partial t}=0 \tag{9.4.59}$$

We see easily that the units of F/ρ_l are those of the square of velocity $[\text{ms}^{-1}]$ as required by dimensional analysis. To simplify the notations, we put:

$$v=\sqrt{\frac{F}{\rho_l}} \tag{9.4.60}$$

and therefore:

$$\frac{\partial^2 y}{\partial x^2}-\frac{1}{v^2}\frac{\partial^2 y}{\partial t}=0 \tag{9.4.61}$$

We will now consider a very interesting case in the context of musicology which is that of the tense string (most string instruments works as this).

9.4.3.4.1 Dirichlet Conditions

The goal is in the framework of the previous differential equation (small deformations in the context of musical instruments) to find a function $y(x,t)$ solution of the latter with the following initial conditions that are typical for a musical instrument :

IC1. $y(0,t)=y(L,t)=0$: the extremities A and B of the string are fixed. These are the "Dirichlet boundary conditions".

IC2. $y(x,0)=f(x)$: the initial shape of the string at excitation.

IC3. $\dfrac{\partial y(x,0)}{\partial t}=0$: initial velocity is zero on any point of the string.

The last two conditions are named "Cauchy boundary conditions".

To solve this linear differential equation, we will make use of the variables separation method by writing (see section Differential and Integral Calculus page 1617):

$$y(x,t)=X(x)T(t) \tag{9.4.62}$$

The differential equation:

$$\frac{\partial^2 y}{\partial x^2}-\frac{\rho_l}{F}\frac{\partial^2 y}{\partial t^2}=0 \tag{9.4.63}$$

Therefore becomes:

$$\begin{gathered}\frac{\partial^2 y}{\partial t^2}=\frac{\partial^2(X(x)T(t))}{\partial t^2}=\frac{\partial}{\partial t}\left(\underbrace{\frac{\partial X(x)}{\partial t}}_{=0}T(t)+X(x)\frac{\partial T(t)}{\partial t}\right)=X(x)\frac{\partial^2 T(t)}{\partial t^2}=\frac{F}{\rho_l}\frac{\partial^2 y}{\partial x^2}\\ \frac{\partial^2 y}{\partial x^2}=\frac{\partial^2(X(x)T(t))}{\partial x^2}=\frac{\partial}{\partial x}\left(\frac{\partial X(x)}{\partial x}T(t)+X(x)\underbrace{\frac{\partial T(t)}{\partial x}}_{=0}\right)=T(t)\frac{\partial^2 X(x)}{\partial x^2}\end{gathered} \tag{9.4.64}$$

So we have:

$$\frac{\dfrac{\partial^2 X}{\partial x^2}}{X}=\frac{\rho_l}{F}\frac{\dfrac{\partial^2 T}{\partial x^2}}{T} \tag{9.4.65}$$

By putting the second relation in the first, we get:

$$\begin{gathered}X(x)\frac{\partial^2 T(t)}{\partial t^2}=\frac{F}{\rho_l}\frac{\partial^2 y}{\partial x^2}\\ \frac{\partial^2 y}{\partial x^2}=T(t)\frac{\partial^2 X(x)}{\partial x^2}\end{gathered} \tag{9.4.66}$$

The left term of the last relation does not contain the variable t and the right does not contain x. The only way to equalize these two expressions is to consider each as a constant, which we will denote by $-\lambda^2$ such that:

$$\frac{\dfrac{\partial^2 X}{\partial x^2}}{X}=\frac{\rho_l}{F}\frac{\dfrac{\partial^2 T}{\partial x^2}}{T}=c^{te}=-\lambda^2 \tag{9.4.67}$$

Thus, we have two differential equations:

$$\frac{\partial^2 X}{\partial x^2}+\lambda^2 X=0 \qquad \text{and} \qquad \frac{\partial^2 T}{\partial t^2}+(v\lambda)^2 T=0 \tag{9.4.68}$$

These two equations are similar, we solve them in a general way (see section Differential and Integral Calculus page 1610):

$$\frac{\partial^2 \alpha(t)}{\partial t^2}+\beta\alpha(t)=0 \qquad \text{with } \beta\in\mathbb{R}^+ \tag{9.4.69}$$

The characteristic equation is then:

$$r^2+\beta=0\Rightarrow\Delta=b^2-4ac=-4\beta \tag{9.4.70}$$

hence:

$$r_{1,2}=\frac{\pm\sqrt{-4\beta}}{2}=\pm\mathrm{i}\sqrt{\beta}=u\pm\mathrm{i}v=0\pm\mathrm{i}v \tag{9.4.71}$$

We know that the general solution if the roots of the characteristic equation are complex ($r_{1,2}\in\mathbb{C}$) is the of the form:

$$\alpha(t)=C_1e^{ut}\cos(vt)+C_2e^{ut}\sin(vt)=C_1\cos(\sqrt{\beta}t)+C_2\sin(\sqrt{B}t) \tag{9.4.72}$$

For our two differential equations, so we have by similitude:

$$\begin{gathered}X(x)=A_1\cos(\lambda x)+B_1\sin(\lambda x)\\ T(t)=A_2\cos(\lambda vt)+B_2\sin(\lambda vt)\end{gathered}\tag{9.4.73}$$

This gives for the solution of our wave equation:

$$y(x,t)=X(x)T(t)=(A_1\cos(\lambda x)+B_1\sin(\lambda x)(A_2\cos(\lambda vt)+B_2\sin(\lambda vt))\tag{9.4.74}$$

Let us determine the constants A_i,B_i by taking into account the initial conditions:

$$y(0,t)=0\Rightarrow 0=A_1(A_2\cos(\lambda vt)+B_2\sin(\lambda vt)),\forall t\Rightarrow A_1=0\tag{9.4.75}$$

Then it only remains:

$$y(x,t)=(B_1\sin(\lambda x))(A_2\cos(\lambda vt)+B_2\sin(\lambda vt))=\sin(\lambda x)(B_1A_2\cos(\lambda vt)+B_1B_2\sin(\lambda vt))\tag{9.4.76}$$

Let us put:

$$B_1B_2=a,\,B_1A_2=b\Rightarrow y(x,t)=\sin(\lambda x)(b\cos(\lambda vt)+a\sin(\lambda vt))\tag{9.4.77}$$

The initial condition $y(L,t)=0,\forall t$ brings us to put that:

$$\begin{aligned}&\sin(\lambda L)=0\Rightarrow\lambda L=n\pi\Rightarrow\lambda=\frac{n\pi}{L},n\in\mathbb{N}\\ &\Rightarrow y(x,t)=\sin\left(\frac{n\pi x}{L}\right)\left[b\cos\left(\frac{n\pi v}{L}t\right)+a\sin\left(\frac{n\pi v}{L}t\right)\right]\end{aligned}\tag{9.4.78}$$

To take into account the zero initial speed, we derivate $y(x,t)$ with respect to time:

$$\begin{aligned}&\frac{\partial y(x,t)}{\partial t}=\sin\left(\frac{n\pi x}{L}\right)\left[-b\frac{n\pi v}{L}\sin\left(\frac{n\pi v}{L}t\right)+a\frac{n\pi v}{L}\cos\left(\frac{n\pi v}{L}t\right)\right]\\ &\Rightarrow\frac{\partial y(x,0)}{\partial t}=\sin\left(\frac{n\pi x}{L}t\right)\left[a\frac{n\pi v}{L}\cos(0)\right]\Rightarrow a=0\end{aligned}\tag{9.4.79}$$

It only remains:

$$y(x,t)=b\sin\left(\frac{n\pi x}{L}t\right)\cos\left(\frac{n\pi v}{L}t\right)\qquad y(x,t)\in[-b,+b]\tag{9.4.80}$$

The constant b represents the amplitude of the transverse displacement of the string. As this amplitude can not be the same everywhere at a given time and a given location for any kind of excitement satisfying the initial conditions, there must be as many values b_n as we choose values of n in $n\pi x/\lambda l$.

The principle of superposition of the solutions of linear differential equations (see section Differential and Integral Calculus page 1605) permits us to write that the linear combination of all solution for the string is therefore:

$$y(x,t)=\sum_{i=1}^{+\infty}b_n\sin\left(\frac{n\pi x}{L}\right)\cos\left(\frac{n\pi v}{L}t\right)\tag{9.4.81}$$

The b_n must be choose to satisfy the initial conditions that gives the shape of the perturbation:

$$f(x)=y(x,0)=\sum_{i=1}^{+\infty} b_n \sin\left(\frac{n\pi x}{L}\right)\cos(0)=\sum_{i=1}^{+\infty} b_n \sin\left(\frac{n\pi x}{L}\right) \tag{9.4.82}$$

This expression for $f(x)$ suggest to compare it at a Fourier series development (see section Sequences and Series page 1758):

$$f(x)=\sum_{n=0}^{+\infty}(a_n\cos(nkx)+b_n\sin(nkx)) \tag{9.4.83}$$

In which $k=\pi/L$ and $a_n=0,\forall n$. Fourier's theorem requires the b_n are given by (see section Sequences and Series page 1727):

$$b_0=0 \qquad b_n=\frac{2}{L}\int_0^L f(x)\sin(nkx)\mathrm{d}x \tag{9.4.84}$$

Let us now imagine a string of length L fixed at its ends and tense. Let us choose the simplest possible excitation form: we scratch the string in its middle in a very quick way, to take it away from a very small distance H from its equilibrium position.

The initial disturbance $y(x,0)$ is then:

$$\begin{aligned} f(x)&=\frac{2Hx}{L} && \text{for } 0\leq x\leq\frac{L}{2}\\ f(x)&=\frac{2H(L-x)}{L} && \text{for } \frac{L}{2}\leq x\leq L \end{aligned} \tag{9.4.85}$$

Let us now compute the Fourier coefficients:

$$\begin{aligned} b_n&=\frac{2}{L}\int\limits_0^L f(x)\sin\left(\frac{n\pi x}{L}\right)\mathrm{d}x\\ &=\frac{2}{L}\left\{\int\limits_0^{L/2}\frac{2Hx}{L}\sin\left(\frac{n\pi x}{L}\right)\mathrm{d}x+\int\limits_{L/2}^{L}\frac{2H(L-x)}{L}\sin\left(\frac{n\pi x}{L}\right)\mathrm{d}x\right\} \end{aligned} \tag{9.4.86}$$

Therefore:

$$b_n=\frac{8H}{\pi^2}\frac{\sin\left(n\frac{\pi}{2}\right)}{n^2} \tag{9.4.87}$$

The wave function becomes:

$$y(x,t)=\sum_{n=1}^{+\infty} b_n\sin\left(\frac{n\pi x}{L}\right)\cos\left(\frac{n\pi v}{L}t\right)=\frac{8H}{\pi^2}\sum_{n=1}^{+\infty}\frac{\sin\left(n\frac{\pi}{2}\right)}{n^2}\sin\left(\frac{n\pi x}{L}\right)\cos\left(\frac{n\pi v}{L}t\right) \tag{9.4.88}$$

Because of the $\sin\left(n\dfrac{\pi}{2}\right)$, the terms for which n is even are all zero. Then it remains:

$$y(x,t)=\frac{8H}{\pi^2}\left[\begin{array}{c}\dfrac{1}{1^2}\sin\left(\dfrac{\pi x}{L}\right)\cos\left(\dfrac{\pi v}{L}t\right)-\dfrac{1}{3^2}\sin\left(\dfrac{3\pi x}{L}\right)\cos\left(\dfrac{3\pi v}{L}t\right)+\\ \dfrac{1}{5^2}\sin\left(\dfrac{\pi x}{L}\right)\cos\left(\dfrac{\pi v}{L}t\right)-\ldots\end{array}\right] \tag{9.4.89}$$

If we retain only the term $n=1$, we keep obviously only:

$$y(x,t)=\frac{8H}{\pi^2}\sin\left(\frac{\pi x}{L}\right)\cos\left(\frac{\pi v}{L}t\right)=\frac{8H}{\pi^2}\sin\left(\frac{2\pi}{2L}x\right)\cos\left(\frac{2\pi}{2L}vt\right)=\frac{8H}{\pi^2}\sin(k_1x)\cos(kvt) \tag{9.4.90}$$

We have:

$$k_1=\frac{2\pi}{2L} \tag{9.4.91}$$

that is the wavenumber corresponding the wavelength:

$$\lambda_1=\frac{2\pi}{k_1}=2L \tag{9.4.92}$$

and:

$$k_1v=\omega_1=2\pi f_1\Rightarrow f_1=\frac{k_1v}{2\pi}=\frac{v}{2L}=\frac{1}{2L}\sqrt{\frac{F}{\rho_l}} \tag{9.4.93}$$

which is the first harmonic frequency vibration of the string.

Thus, for any value n, it is easy to show that the n-th "eigenmode" is given by:

$$y_n(x,t)=\frac{\hat{y}}{n^2}\sin\left(\frac{2\pi}{\lambda_n}x\right)\cos\left(\frac{2\pi}{f_n}t\right) \tag{9.4.94}$$

with:

$$\boxed{\lambda_n=\frac{2L}{n}\qquad f_n=\frac{n}{2L}\sqrt{\frac{F}{\rho_l}}} \tag{9.4.95}$$

relations named "Mersenne's laws" (11644-11648 according to holocene calendar) where the mode of lower frequency with n being equal to 1 is named the "fundamental mode" associated with its "fundamental frequency".

Thus, after being scratched quickly in the middle of its length L, a string held rigidly at both ends can oscillate in several modes. The fundamental mode $n=1$ (fundamental harmonic) is the lowest possible frequency. It corresponds to it the wavelength $\lambda=2L$.

The n higher order frequencies are named "harmonic frequencies". For the same initial displacement H, the maximum amplitude of the vibration decreases according to n^{-2} as we see it in the expression of our function above.

Another way to excite the string is make it oscillates sinusoidally, which means therefore that $y(x,t)$ is of the form:

$$y(x,t)=y(x)\sin(\omega t-\phi) \tag{9.4.96}$$

Substituting this relation in the string wave equation, we get:

$$\frac{\mathrm{d}^2y(x)}{\mathrm{d}x^2}+\omega^2\frac{\rho_l}{F}y(x)=0 \tag{9.4.97}$$

The solution is then reduce to:

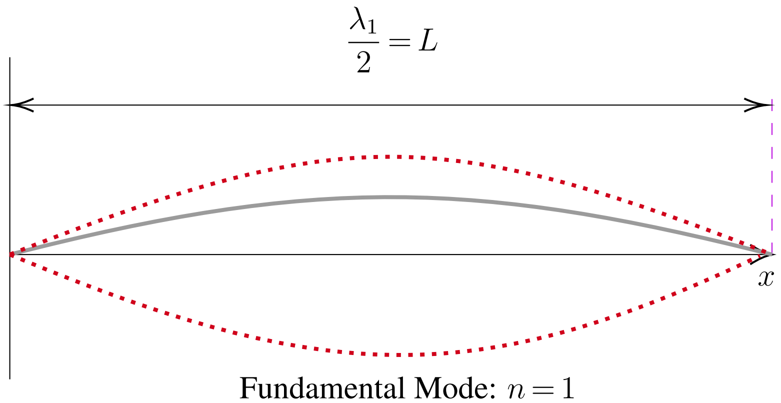
$$y(x)=\sum_{n=1}^{+\infty}b_n\sin\left(\frac{n\pi x}{L}\right) \quad \text{or} \quad y_n(x)=b_n\sin\left(\frac{n\pi x}{L}\right) \quad \forall n\in\mathbb{N}^* \tag{9.4.98}$$

The value $n=0$ can not be included because it gives a string without excitement. By this function in the previous wave equation and simplifying, we get trivially:

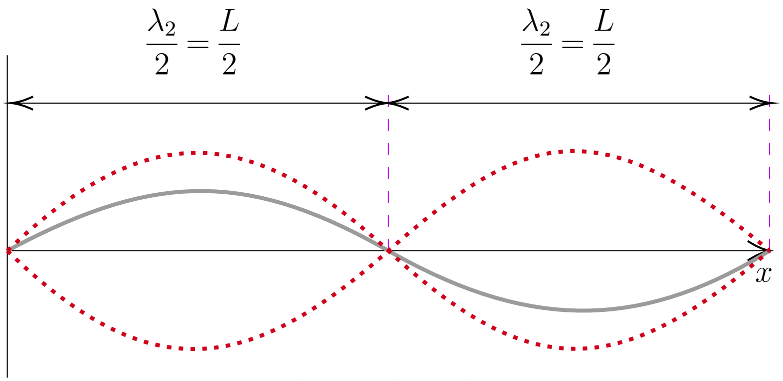
$$\omega_n=\frac{n\pi}{L}\sqrt{\frac{F}{\rho_l}} \tag{9.4.99}$$

These are the "Dirichlet's oscillations frequencies" of a string. The strings of a violin, for example, are Dirichlet strings.

Remember the image seen previously above but focusing this time only on two harmonics:



Fundamental Mode: $n=1$



$\frac{\lambda_2}{2}=\frac{L}{2}$
$\frac{\lambda_2}{2}=\frac{L}{2}$
x

Fundamental Mode: $n=2$

Figure 9.119: First two basic modes of a fixed string

The same analogies, reasoning and developments can be made with the Neumann conditions below.

Remarks

R1. As we have just seen the theory predicts that the vibration can be a linear combination of several modes. This phenomenon is named "simultaneous vibration". It occurs abundantly in a piano.

R2. Many musical instruments are designed to emit sounds with conventional frequencies, being admit that the note recognized by the ear is defined by the fundamental frequency, for example: Do (264 Hertz), The (440 Hertz). For more details see the section of Mathematical Music.

R3. During the construction of musical string instrument, we decide the value of ρ_l (by choosing the diameter and the nature of the string) and we determine its length L by seeking the compromise between the loudness we want to emit and the mechanical strength that the instrument that must support the tension forces F.

9.4.3.4.2 Neumann Conditions

Alternatively to Dirichlet's conditions where the ends are fixed and of equal height, the Neumann conditions assume that the ends are small loops allowed to slide along two bars without friction.

For our string, the Neumann conditions specify the values $\partial y/\partial x$ at the ends. But as the loops are supposed massless and without friction, the derivative $\partial x/\partial x$ must cancel at the end $x=\{0,L\}$ (this is an assumption not easy to guess this is why it has a name...!). If this were not the case, then by the nullity of the mass of the end, the shift will be due to an infinite acceleration, which can not be allowed non-relativistic framework! This is what we require instead of the Dirichlet condition, the Neumann condition is defined by:

IC3. $\dfrac{\partial y}{\partial x}(0,t)=\dfrac{\partial y}{\partial x}(L,t)=0$

the conditions IC1, IC2 remaining the same.

This change of status does not prevent the variables separation method of resolution to be the same as before and that we will fall identically on the following relation to which we will apply the new initial condition (let us know if you want we put the details again):

$$y(x,t)=X(x)T(t)=(A_1\cos(\lambda x)+B_1\sin(\lambda x))(A_2\cos(\lambda vt)+B_2\sin(\lambda vt)) \tag{9.4.100}$$

on which we therefore apply the Neumann conditions:

$$\begin{aligned}&\frac{\partial y}{\partial x}(0,t)=0\\&\frac{\partial y}{\partial x}=\lambda\left(-A_1\sin(\lambda x)+B_1\cos(\lambda x)\right)\left(A_2\cos(\lambda vt)+B_2\sin(\lambda vt)\right)\\&\frac{\partial y}{\partial x}(0,t)=0\Rightarrow\lambda B_1(A_2\cos(\lambda vt)+B_2\sin(\lambda vt))=0,\forall t\Rightarrow B_1=0\end{aligned} \tag{9.4.101}$$

Then it remains:

$$y(x,t)=\cos(\lambda x)(A_1A_2\cos(\lambda vt)+A_1B_2\sin(\lambda vt)) \tag{9.4.102}$$

by putting $b=A_1A_2$,$a=A_1B_2$ the function simplifies in:

$$y(x,t)=\cos(\lambda x)(b\cos(\lambda vt)+a\sin(\lambda vt)) \tag{9.4.103}$$

The initial condition $\partial y/\partial x(L,t)=0,\forall t$ requires:

$$\begin{aligned}&-\sin(\lambda L)=0\Rightarrow\lambda L=n\pi\Rightarrow\lambda=\frac{n\pi}{L}\qquad n\in\mathbb{N}\\&\Rightarrow y(x,t)=\cos\left(\frac{n\pi x}{L}\right)\left[b\cos\left(\frac{n\pi v}{L}t\right)+a\sin\left(\frac{n\pi v}{L}t\right)\right]\end{aligned} \tag{9.4.104}$$

The same developments for the IC2. we have made with the Dirichlet condition IC1 then apply equally (we can write the details on request):

$$y(x,t)=b\cos\left(\frac{n\pi x}{L}\right)\cos\left(\frac{n\pi x}{L}t\right) \tag{9.4.105}$$

then, the analogy with Fourier series applies similarly but with the cosine in place of the sine.

The Neumann frequencies of a string are the same as for the Dirichlet either:

$$\omega_n = \frac{n\pi}{L}\sqrt{\frac{F}{\rho_l}} \tag{9.4.106}$$

The particularity, however, is the value of spatial function that is trivially this time:

$$y(x)=\sum_{n=0}^{+\infty} b_n \cos\left(\frac{n\pi x}{L}\right) \quad \text{or} \quad y_n(x)=b_n\cos\left(\frac{n\pi x}{L}\right) \qquad n\in\mathbb{N} \tag{9.4.107}$$

Indeed, for $n=0$ we have this time an identical amplitude b_n which is transmitted along the string without that it does vibrates!!!

Let us also notice that the function $y(x,t)=at+b$ also fully satisfies the three initial conditions including that of Neumann.

Indeed, we have well:

IC1. $\dfrac{\partial y}{\partial x}(0,t)=\dfrac{\partial y}{\partial x}(L,t)=0$

IC2. $y(x,0)=f(x)=b$

IC3. $\dfrac{\partial y(x,0)}{\partial t}=0$

and in addition, $y(x,t)=at+b$ satisfies also the wave equation:

$$\frac{\partial^2 y}{\partial x^2}-\frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}=0 \tag{9.4.108}$$

9.4.4 Non-relativistic Lagrangian of a String

We will now determine the non-relativistic Lagrangian of a string, calculation that will be us useful to us for our study of String Theory in the chapter of Cosmology.

We keep our string having a constant linear density and tension whose ends are located at $x=0, x=L$ and the speed of for which the transversal speed is not relativistic $v\ll c$.

The kinetic energy is then simply the sum of the kinetic energies of each infinitesimal element of the string. We can then write in Lagrangian notation:

$$T=\int_0^L \frac{1}{2}(\rho_l \mathrm{d}x)\left(\frac{\partial y}{\partial t}\right)^2 \tag{9.4.109}$$

The potential energy is involved in the elongation of the string from which an infinitesimal portion can be seen as varying from $(x,0)$ to $(x+\mathrm{d}x,0)$ when the string is in equilibrium.

When a string is momentarily stressed from (x,y) to $(x+\mathrm{d},y+\mathrm{d}y)$ then the variation of the length $\mathrm{d}l$ of an infinitesimal element of the string is trivially given by:

$$\mathrm{d}l=\sqrt{(\mathrm{d}x)^2+(\mathrm{d}y)^2}-\mathrm{d}x=\mathrm{d}x\left(\sqrt{1+\left(\frac{\partial y}{\partial x}\right)^2}-1\right)\cong\mathrm{d}x\frac{1}{2}\left(\frac{\partial y}{\partial x}\right)^2 \tag{9.4.110}$$

We used above for the approximation the Taylor expansion at the second order (see section Sequences and Series page 1703), which gives us:

$$\sqrt{1+x}=1+\frac{1}{2}x-\frac{1}{2\cdot 4}x^2+\frac{1\cdot 3}{2\cdot 4\cdot 6}x^3-\ldots \qquad |x|\leq 1 \tag{9.4.111}$$

The work done to stretch every infinitesimal element being $F\Delta l$, the total potential energy is then expressed as:

$$V=\int\limits_0^L F\mathrm{d}l\cong\int\limits_0^L\frac{1}{2}F\left(\frac{\partial y}{\partial x}\right)^2\mathrm{d}x \tag{9.4.112}$$

The Lagrangian being defined by $L=T-V$ (see section Analytical Mechanics page 3152), then we have:

$$L=\int\limits_0^L\left[\frac{1}{2}\rho_l\left(\frac{\partial y}{\partial t}\right)-\frac{1}{2}F\left(\frac{\partial y}{\partial x}\right)^2\right]\mathrm{d}x=\int\limits_0^L\mathcal{L}\mathrm{d}x \tag{9.4.113}$$

where $\mathcal{L}$ is defined, well correctly, as the "Lagrangian density of a string":

$$\boxed{\mathcal{L}=\frac{1}{2}\rho_l\left(\frac{\partial y}{\partial t}\right)-\frac{1}{2}F\left(\frac{\partial y}{\partial x}\right)^2} \tag{9.4.114}$$

The action of the string is therefore:

$$S=\int\limits_{t_i}^{t_f}L\mathrm{d}t=\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\frac{1}{2}\rho_l\left(\frac{\partial y}{\partial t}\right)-\frac{1}{2}F\left(\frac{\partial y}{\partial x}\right)^2\right] \tag{9.4.115}$$

In this action, the path of action is the function $y(x,t)$. To find the equations of motion, we must consider the variation of the action when we vary:

$$y(x,t)\rightarrow y(x,t)+\delta y(x,t) \tag{9.4.116}$$

Which gives:

$$\begin{aligned}\delta S&=\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\frac{1}{2}\rho_l\left(\frac{\partial(y(x,t)+\delta y(x,t))}{\partial t}\right)^2-\frac{1}{2}F\left(\frac{\partial(y(x,t)+\delta y(x,t))}{\partial x}\right)^2\right]\\&=\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\begin{array}{l}\frac{1}{2}\rho_l\left(\frac{\partial y(x,t)^2}{\partial t^2}+\frac{2\partial y(x,t)\partial(\delta y(x,t))}{\partial t^2}+\frac{\partial(\delta y(x,t))^2}{\partial t^2}\right)\\-\frac{1}{2}F\left(\frac{\partial y(x,t)^2}{\partial x^2}+\frac{2\partial y(x,t)\partial(\delta y(x,t))}{\partial x^2}+\frac{\partial(\delta y(x,t))^2}{\partial x^2}\right)\end{array}\right]\\&\cong\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\rho_l\frac{\partial y}{\partial t}\frac{\partial(\delta y(x,t))}{\partial t}-F\frac{\partial y}{\partial x}\frac{\partial(\delta y(x,t))}{\partial x}\right]\\&=\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\rho_l\frac{\partial y}{\partial t}\frac{\partial(\delta y)}{\partial t}-F\frac{\partial y}{\partial x}\frac{\partial(\delta y)}{\partial x}\right]\end{aligned}\tag{9.4.117}$$

As:

$$\left(\frac{\partial(\delta y(x,t))}{\partial t}\right)^2\ll\left(\frac{\partial y(x,t)}{\partial t}\right)^2\ll\frac{2\partial y(x,t)\partial(\delta y(x,t))}{\partial t^2}\tag{9.4.118}$$

and this identically for the second term.

We should not have time derivatives acting on the variations. Then using the following trivial relation on the first term:

$$\frac{\partial}{\partial t}\rho_l\left(\frac{\partial y}{\partial t}\delta y\right)=\rho_l\frac{\partial^2y}{\partial t^2}\delta y+\rho_l\frac{\partial y}{\partial t}\frac{\partial(\delta y)}{\partial t}\Rightarrow\rho_l\frac{\partial(\delta y)}{\partial t}=\frac{\partial}{\partial t}\rho_l\left(\frac{\partial y}{\partial t}\delta y\right)-\rho_l\frac{\partial^2y}{\partial t^2}\delta y\tag{9.4.119}$$

and identically on the second, we can rewrite the action:

$$\begin{aligned}\delta S=&\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\rho_l\frac{\partial y}{\partial t}\frac{\partial(\delta y)}{\partial t}-F\frac{\partial y}{\partial x}\frac{\partial(\delta y)}{\partial x}\right]\\=&\int_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left[\frac{\partial}{\partial t}\left(\rho_l\frac{\partial y}{\partial t}\delta y\right)-\rho_l\frac{\partial^2y}{\partial t^2}\delta y+\frac{\partial}{\partial x}\left(-F\frac{\partial y}{\partial x}\delta y\right)+F\frac{\partial^2y}{\partial x^2}\delta y\right]\\=&\int\limits_{t_i}^{t_f}\left(\rho_l\frac{\partial y}{\partial t}\delta y\right)\int\limits_0^L\mathrm{d}x-\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\rho_l\frac{\partial^2y}{\partial t^2}\delta y+\int\limits_0^L\partial\left(-F\frac{\partial y}{\partial x}\delta y\right)\int\limits_{t_i}^{t_f}\mathrm{d}t+\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}xF\frac{\partial^2y}{\partial x^2}\delta y\end{aligned}\tag{9.4.120}$$

As we have seen it in the section of Analytical Mechanics, the correct path is given by $\delta S=0$. Therefore, we must have:

$$\boxed{\delta S=\int\limits_0^L\left[\rho_l\frac{\partial y}{\partial t}\delta y\right]_{t_i}^{t_f}\mathrm{d}x+\int\limits_{t_i}^{t_f}\left[-F\frac{\partial y}{\partial x}\delta y\right]_0^L\mathrm{d}t-\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left(\rho_l\frac{\partial^2y}{\partial t^2}-F\frac{\partial^2y}{\partial x^2}\right)\delta y=0}\tag{9.4.121}$$

Thus our expression contains three terms. Each of these terms must vanish independently as we shall see:

1. The cancellation of the third term is done following a trivial condition that we are already well known (hopefully ...):

   $$\int\limits_{t_i}^{t_f}\mathrm{d}t\int\limits_0^L\mathrm{d}x\left(\rho_l\frac{\partial^2 y}{\partial t^2}-F\frac{\partial^2 y}{\partial x^2}\right)\delta y=0\Rightarrow\rho_l\frac{\partial^2 y}{\partial t^2}-F\frac{\partial^2 y}{\partial x^2}=0 \tag{9.4.122}$$

   and therefore:

   $$\frac{\partial^2 y}{\partial x^2}-\frac{\rho_l}{F}\frac{\partial^2 y}{\partial t^2}=0 \tag{9.4.123}$$

   So we fall back on the differential equation of a transverse wave as we had proved earlier above. Our hypothesis about the third term can then only be correct as well as the expression of our action.

2. The first term is determined by the configuration of the string at the times t_i,t_f:

   $$\int\limits_0^L\left[\rho_l\frac{\partial y}{\partial t}\delta y\right]_{t_i}^{t_f}\mathrm{d}x \tag{9.4.124}$$

   Now, if we apply the knowledge of these configurations in time, we have by definition:

   $$\delta y(x,t_f)=\delta y(x,t_i)=0 \tag{9.4.125}$$

   (total knowledge of the action path as knowledge of the initial conditions, so no variation). This validates once again the expression of our action and the zero value of this term as expected.

3. The second term is a little more interesting:

   $$\int\limits_{t_i}^{t_f}\left[-F\frac{\partial y}{\partial x}\delta y\right]_0^L\mathrm{d}t \tag{9.4.126}$$

   First, it is only because we know the positions of the ends of the string that we can know its vibration modes, we know that well! So we have to know how the ends behave. For that we will come back on things that are well known to us: the Dirichlet and Neumann conditions of a string.

   Suppose we assume the Dirichlet conditions (see above), the ends are then fixed and we will have necessarily at those ends:

   $$\delta y(0,t)=\delta y(L,t)=0 \tag{9.4.127}$$

   and then the second term vanish well (phew!).

   If, in contrast, we choose the ends to move freely, then the variations:

   $$\delta y(0,t)=\delta y(L,t)=0 \tag{9.4.128}$$

   are unconstrained and therefore, only the Neumann conditions:

   $$\frac{\partial y}{\partial x}(t,0)=\frac{\partial y}{\partial x}(t,L)=0 \tag{9.4.129}$$

(see above for more details) will permit us to have the second term of the action equal to zero.

To be fully aware of the importance of these initial conditions, let us consider the linear momentum p_y carried by the string (there are no other motion of the as we have implicitly assumed a transverse-excitement from since the beginning only in this direction y).

The linear momentum is simply the sum of the linear momentum of each infinitesimal element along the string:

$$p_y = \int\limits_0^L (\rho_l \mathrm{d}x)\frac{\partial y}{\partial t} \tag{9.4.130}$$

Let us check out by curiosity (it's an anticipated curiosity ...) if the momentum is well preserved:

$$\frac{\mathrm{d}p_y}{\mathrm{d}t} = \int\limits_0^L (\rho_l \mathrm{d}x)\frac{\partial^2 y}{\partial t^2} = \int\limits_0^L F\frac{\partial^2 y}{\partial x^2}\mathrm{d}x = F\frac{\partial y}{\partial x}\bigg|_{x=0}^{x=L} \tag{9.4.131}$$

where we have used the transverse wave equation for the substitution.

We see by the result of this little calculation that the momentum is trivially conserved if we impose the Neumann conditions, whereas for the Dirichlet conditions, most of time conservation is not respected! Indeed, it is trivial (there is no need for calculations to realize it normally), when the ends of the string are attached to the wall, the wall constantly exerts a force on the string.

9.4.5 Vibrational modes of a circular membrane

A two-dimensional elastic membrane under tension can support transverse vibrations. The properties of an idealized drumhead can be modelled by the vibrations of a circular membrane of uniform thickness, attached to a rigid frame. Due to the phenomenon of resonance, at certain vibration frequencies, its resonant frequencies, the membrane can store vibrational energy, the surface moving in a characteristic pattern of standing waves. This is named a "normal mode". A membrane has an infinite number of these normal modes, starting with a lowest frequency one named the fundamental mode.

There exist infinitely many ways in which a membrane can vibrate, each depending on the shape of the membrane at some initial time, and the transverse velocity of each point on the membrane at that time. The vibrations of the membrane are given by the solutions of the two-dimensional wave equation with Dirichlet boundary conditions which represent the constraint of the frame. It can be shown that any arbitrarily complex vibration of the membrane can be decomposed into a possibly infinite series of the membrane's normal modes. This is analogous to the decomposition of a time signal into a Fourier series.

We derive the phenomenon of vibration of a circular membrane in tension (typically a drum) in the same manner that the transverse vibration of a string whose equation was for recall:

$$\frac{\partial^2 y}{\partial x^2} - \frac{\rho_l}{F}\frac{\partial^2 y}{\partial t^2} = 0 \tag{9.4.132}$$

But first if we consider a vertical slice of the drum we change y by z as we work in 3D space and that the z-axes is perpendicular to the dream membrane:

$$\frac{\partial^2 z}{\partial x^2}-\frac{\rho_l}{F}\frac{\partial^2 z}{\partial t^2}=0 \tag{9.4.133}$$

By the central symmetry of the problem we can also write (as the general solution is the sum of special solutions and we will consider that the force F takes into account the sum of the special cases):

$$\frac{\partial^2 z}{\partial x^2}+\frac{\partial^2 z}{\partial y^2}-\frac{\rho_l}{F}\frac{\partial^2 z}{\partial t^2}=0 \tag{9.4.134}$$

However, the linear density ρ_l of the string must be replaced by the surface density ρ_s of the membrane denoted σ by tradition. And for the coherence of units we must replace the unidirectional tension force F of the string by a tension force applied on the periphery of the membrane. This force is exerted in all directions of the plane and is described per unit length:

$$\tau=\frac{\mathrm{d}F}{\mathrm{d}l} \tag{9.4.135}$$

So finally:

$$\frac{\partial^2 z}{\partial x^2}+\frac{\partial^2 z}{\partial y^2}-\frac{\sigma}{\frac{F}{l}}\frac{\partial^2 z}{\partial t^2}=0 \tag{9.4.136}$$

Or in a shorter way using the Laplace operator (see section Vector Calculus page 1899):

$$\vec{\nabla}^2 z-\frac{\sigma}{\tau}\frac{\partial^2 z}{\partial t^2}=0 \tag{9.4.137}$$

Or in a more conventional way:

$$\boxed{\vec{\nabla}^2 z=\frac{1}{v^2}\frac{\partial^2 z}{\partial t^2}} \tag{9.4.138}$$

with:

$$\boxed{v=\sqrt{\frac{\tau}{\sigma}}} \tag{9.4.139}$$

We seek the particular solution of the Laplace equation which satisfies the following conditions:

IC1. The membrane is fixed on its circular periphery R (boundary conditions)

IC2. The initial position and speed are given (initial conditions)

The symmetry of the problem suggests using the Laplacian of a scalar field in polar coordinates (see section Vector Calculus page 1899):

$$\frac{\partial^2 z}{\partial r^2}+\frac{1}{r}\frac{\partial z}{\partial r}+\frac{1}{r^2}\frac{\partial^2 z}{\partial \theta^2}=\frac{1}{v^2}\frac{\partial^2 z}{\partial t^2} \tag{9.4.140}$$

And the fixed conditions:

C1. $\forall t \geq 0, \forall \theta \in [0,2\pi], z(r,\theta,t)=0$ (boundary conditions)

C2. $\forall \theta \in [\theta,2\pi], \forall r \in [0,R] \begin{cases} z(r,\theta,0)=f(r,\theta) \\ \partial_t z(r,\theta,0)=g(r,\theta) \end{cases}$ (initial conditions)

where the functions f,g representing the shape of the drum at $t=0$ and the speed of its membrane also at $t=0$ must be given.

Again, to find the solution, we will use the method of separation of the variables (see section Differential and Integral Calculus page 1617) such that:

$$z(r,\theta,t)=X(r,\theta)T(t) \tag{9.4.141}$$

and as identically as for the rope:

$$\frac{\dfrac{\partial^2 X}{\partial x^2}}{x}=\frac{1}{v^2}\frac{\dfrac{\partial^2 T}{\partial t^2}}{T} \tag{9.4.142}$$

and identically that for the rope, we get for the temporal part T a solution of the type:

$$T(t)=A\cos(\lambda vt)+B\sin(\lambda vt) \tag{9.4.143}$$

For $X(r,\theta)$ the method changes with respect to the case of the rope seen above because we now have a differential equation with two variables such that:

$$\frac{\partial^2 X(r,\theta)}{\partial (r,\theta)^2}+\lambda^2 x(r,\theta)=0 \tag{9.4.144}$$

To integrate this last equation, we will seek the solutions also in the following separated form:

$$X(r,\theta)=R(r)\Theta(\theta) \tag{9.4.145}$$

we get by putting this in the differential equation:

$$R''\Theta+\frac{1}{r}R'\Theta+\frac{1}{r^2}R\Theta''+\lambda^2 R\Theta=0 \tag{9.4.146}$$

because for recall we have in polar coordinates (see section Differential and Integral Calculus page 1866):

$$\vec{\nabla}^2 f=\frac{\partial^2 f}{\partial r^2}+\frac{1}{r}\frac{\partial f}{\partial r}+\frac{1}{r^2}\frac{\partial^2 f}{\partial \phi^2} \tag{9.4.147}$$

Hence, by separating the variables:

$$\frac{\Theta''}{\Theta}(\theta)=-\frac{1}{R(r)}\left(r^2R''(r)+rR'(r)+\lambda^2 r^2 R(r)\right) \tag{9.4.148}$$

The left-hand side of the last relation does not contain the variable r and the right-hand side does not contain the variable θ. The only way to equal these two expressions is to consider them each as equal to as constant we will denote μ such that:

$$\frac{\Theta''}{\Theta}(\theta)=\mu=-\frac{1}{R(r)}\left(r^2R''(r)+rR'(r)+\lambda^2 r^2 R(r)\right) \tag{9.4.149}$$

The differential equations verified by R and Θ are then:

$$r^2R''(r)+rR'(r)+\left(\lambda^2r^2+\mu\right)R(r)=0 \qquad \Theta''(\theta)-\mu\Theta(\theta)=0 \tag{9.4.150}$$

The function Θ must obviously be periodic of period 2π, so there exists a natural number n such that $\mu=-n^2$ and therefore identically to the rope, we get quite immediately:

$$\Theta(\theta)=C\cos(n\theta)+D\sin(n\theta) \tag{9.4.151}$$

If we put $\mu=n^2$ in the first differential equation, we get:

$$r^2R''(r)+rR'(r)+(\lambda^2r^2-n^2)R(r)=0 \tag{9.4.152}$$

That we often found in the literature in the following form:

$$R''(r)+\frac{1}{r}R'(r)+\left(\lambda^2-\frac{n^2}{r^2}\right)R(r)=0 \tag{9.4.153}$$

To simplify, we perform the change of variable $x=\lambda r$. That is:

$$x=\lambda r\Rightarrow \mathrm{d}x=\lambda\mathrm{d}r\Rightarrow \mathrm{d}x=\lambda^2\mathrm{d}r^2 \tag{9.4.154}$$

The differential equation therefore becomes:

$$\lambda^2\frac{\mathrm{d}R^2}{\mathrm{d}x^2}+\frac{\lambda^2}{x}\frac{\mathrm{d}R}{\mathrm{d}x}+\left(\lambda^2-\frac{n^2\lambda^2}{x^2}\right)R=0 \tag{9.4.155}$$

After dividing by λ^2 and multiplying by x^2 the differential equation becomes:

$$x^2\frac{\mathrm{d}^2R}{\mathrm{d}x^2}+x\frac{\mathrm{d}R}{\mathrm{d}x}+(x^2-n^2)R=0 \tag{9.4.156}$$

We recognize here the Bessel differential equation of order n as we have introduce it with its special solution in the section of Sequences and Series (see page 1775). Therefore, a special solution is of the type (as the general solution is an infinite sum of Bessel functions by linearity!):

$$R(r)=J_n(x)=J_n(\lambda r) \tag{9.4.157}$$

What ultimately gives us:

$$z(r,\theta,t)=R(r)\Theta(\theta)T(t)=J_n(\lambda r)\left(C\cos(n\theta)+D\sin(n\theta)\right)\left(A\cos(\lambda vt)+B\sin(\lambda vt)\right) \tag{9.4.158}$$

Among the solutions to this equation, let us look for those which satisfy the boundary conditions by putting $R_{\text{membrane}}=L$:

$$\forall\theta\in[0,2\pi],\forall t\geq 0 \qquad R(L)\Theta(\theta)T(t)=0 \tag{9.4.159}$$

Unless Θ or T is the null function, which gives for solution the equilibrium position ... (which probably does not satisfy the initial conditions), we must have $R(L)=0$, that is to say:

$$J_n(\lambda r)=0 \tag{9.4.160}$$

The Bessel function J_n has an infinity of positive zeros that we will denote here by $(\xi_m^n)_{m\in\mathbb{N}}$ (just plot this function with a computer to see it such as with Maple™ 4.00b by writing the command: `>plot(BesselJ(2,x),x=0...100);` where you can change the order value 2 by another value) that provide an infinity of suitable values of λ such that:

$$\lambda_m^n=\frac{\xi_m^n}{L} \tag{9.4.161}$$

This finally corresponds to an infinity of solutions of the initial differential equation that we can write:

$$z_m^n(r,\theta,t)=J_n(\lambda_m^n r)\left[(\alpha_m^n\cos(\omega_m^n t)+\beta_m^n\sin(\omega_m^n t))\cos(n\theta)+(\gamma_m^n\cos(\omega_m^n t)+\delta_m^n\sin(\omega_m^n t))\sin(n\theta)\right] \tag{9.4.162}$$

by having modified the name of the integration constants and having put $\omega_m^n=\lambda_m^n v$ (which verifies the dimensional analysis). Now that this solution satisfies the boundary conditions, we must address the initial conditions.

First for the same reasons as the rope, the general solution is the linear superposition of solutions such as:

$$y(r,\theta,t)=\sum_{n=0}^{+\infty}\sum_{m=1}^{+\infty}y_m^n(r,\theta,t) \tag{9.4.163}$$

We will determine the coefficients α_m^n, β_m^n, γ_m^n, δ_m^n so that the solution $y(r,\theta,t)$ given above also satisfies the initial conditions, that is to say:

$$\begin{aligned}f(r,\theta,0)&=\sum_{n=0}^{+\infty}\sum_{m=1}^{+\infty}J_n(\lambda_m^n r)\left(\alpha_m^n\cos(n\theta)+\gamma_m^n\sin(n\theta)\right)\\ g(r,\theta,0)&=\sum_{n=0}^{+\infty}\sum_{m=1}^{+\infty}\omega_m^n J_n(\lambda_m^n r)\left(\alpha_m^n\cos(n\theta)+\gamma_m^n\sin(n\theta)\right)\end{aligned} \tag{9.4.164}$$

These two relations are similar, let us study the first. It can be written:

$$f(r,\theta,0)=\sum_{n=0}^{+\infty}\left[\left(\sum_{m=1}^{+\infty}\alpha_m^n J_n(\lambda_m^n r)\right)\cos(n\theta)+\left(\sum_{m=1}^{+\infty}\gamma_m^n J_n(\lambda_m^n r)\right)\sin(n\theta)\right] \tag{9.4.165}$$

Which is the Fourier series expansion of the function $f(r,\theta)$ (see section Sequences and Series page 1727). Therefore we have (see section Sequences and Series page 1727):

$$\begin{aligned}\sum_{m=1}^{+\infty}\alpha_m^0 J_n(\lambda_m^0 r)&=\frac{1}{2\pi}\int_{-\pi}^{+\pi}f(r,\theta)\mathrm{d}\theta=f_0(r)\\ \sum_{m=1}^{+\infty}\alpha_m^n J_n(\lambda_m^n r)&=\frac{1}{\pi}\int_{-\pi}^{+\pi}f(r,\theta)\cos(n\theta)\mathrm{d}\theta=f_n(r)\qquad n\in\mathbb{N}^*\\ \sum_{m=1}^{+\infty}\gamma_m^n J_n(\lambda_m^n r)&=\frac{1}{\pi}\int_{-\pi}^{+\pi}f(r,\theta)\sin(n\theta)\mathrm{d}\theta=g_n(r)\qquad n\in\mathbb{N}^*\end{aligned} \tag{9.4.166}$$

Using the orthogonality of the Bessel functions (see section Functional Analysis page 2382) we can deduce from these relations the coefficients α_m^0, α_m^n, γ_m^n (and the same for the others).

For this purpose, let us suppose n fixed and let us put $Z_m(r)=J_n(\lambda_m^n r)$. Let us show that for $m\neq p\Rightarrow Z_m\circ Z_p$ where the dot product is defined for Bessel functions (see section Functional Analysis page 2382):

$$Z_m\circ Z_p=\int\limits_0^L rZ_m(r)Z_p(r)\mathrm{d}r \tag{9.4.167}$$

Since Z_m, Z_p satisfy the differential equation on $R(r)$, we have:

$$\begin{cases} r^2Z'_m+rZ'_m(r)+((\lambda_m^n r)^2-n^2)\,Z_m(r)=0\\ r^2Z'_p+rZ'_p(r)+\left((\lambda_p^n r)^2-n^2\right)\,Z_p(r)=0\end{cases} \tag{9.4.168}$$

By combining these two relations we get:

$$\left((\lambda_p^n)^2-(\lambda_m^n)^2\right)rZ_mZ_p=r(Z''_mZ_p-Z'_pZ_m)+(Z'_mZ_p-Z'_pZ_m)=\left(r(Z'_mZ_p-Z'_pZ_m)\right)' \tag{9.4.169}$$

By integrating member to member between 0 and L and taking into account that:

$$J_n(x)=0 \qquad Z_p(L)=J_n(\lambda_p^n L)=0 \qquad Z_m(L)=J_n(\lambda_m^n L)=0 \tag{9.4.170}$$

we get:

$$\left((\lambda_p^n)^2-(\lambda_m^n)^2\right)\int\limits_0^L rZ_m(r)Z_p(r)\mathrm{d}r=\left(r(Z'_mZ_p-Z'_pZ_m)\right)\Big|_0^L=0 \tag{9.4.171}$$

Hence the result stated earlier since $m\neq p\Rightarrow\lambda_m^n\neq\lambda_p^n$.

The relation:

$$\sum_{m=1}^{+\infty}\alpha_m^nJ_n(\lambda_m^n r)=\frac{1}{\pi}\int\limits_{-\pi}^{+\pi}f(r,\theta)\cos(n\theta)\mathrm{d}\theta=f_n(r) \tag{9.4.172}$$

Can therefore be written:

$$f_n=\sum_{m=1}^{+\infty}\alpha_m^nZ_m \tag{9.4.173}$$

Using the orthogonality Z_m, Z_p for $m\neq p$ we deduce:

$$f_n\circ Z_p=\left(\sum_{m=1}^{+\infty}\alpha_m^nZ_m\right)\circ Z_p=\sum_{m=1}^{+\infty}\alpha(Z_m\circ Z_p)=\alpha_p^n(Z_m\circ Z_p) \tag{9.4.174}$$

The coefficients α_p^n are therefore given by:

$$\alpha_p^n=\frac{f_n\circ Z_p}{Z_\circ Z_p}=\frac{\int_0^L rf_n(r)J_n(\lambda_p^n r)\mathrm{d}r}{\int_0^L r\left(J_n(\lambda_p^n r)\right)^2\mathrm{d}r} \tag{9.4.175}$$

What is not easy to calculate by hand... and this so far... is only for the α_p^n coefficients!!!!!

So we will assume that the reader can imagine that the same process is valid for the other coefficients. To avoid frustration however we will use Maple™ 5.00 to go a little further:

```
> F:=f(r,theta,t);
> wave_eq:=linalg[laplacian](F,[r,theta,z],coords=cylindrical)-diff(F,t,t);

Figure 9.120: Some vibration modes of a circular membrane

In real life with a Chladni plate (from Ernst Florens Friedrich Chladni 11756-11827 according to holocene calendar) that is a thin metal sheet - typically square or circular - mounted at its center and set into vibration so that standing-wave patterns form across its surface; when fine sand or powder is sprinkled on the plate, it migrates toward the nodal lines (the regions that remain still), revealing intricate, symmetric patterns that visually map the plate's vibrational modes.

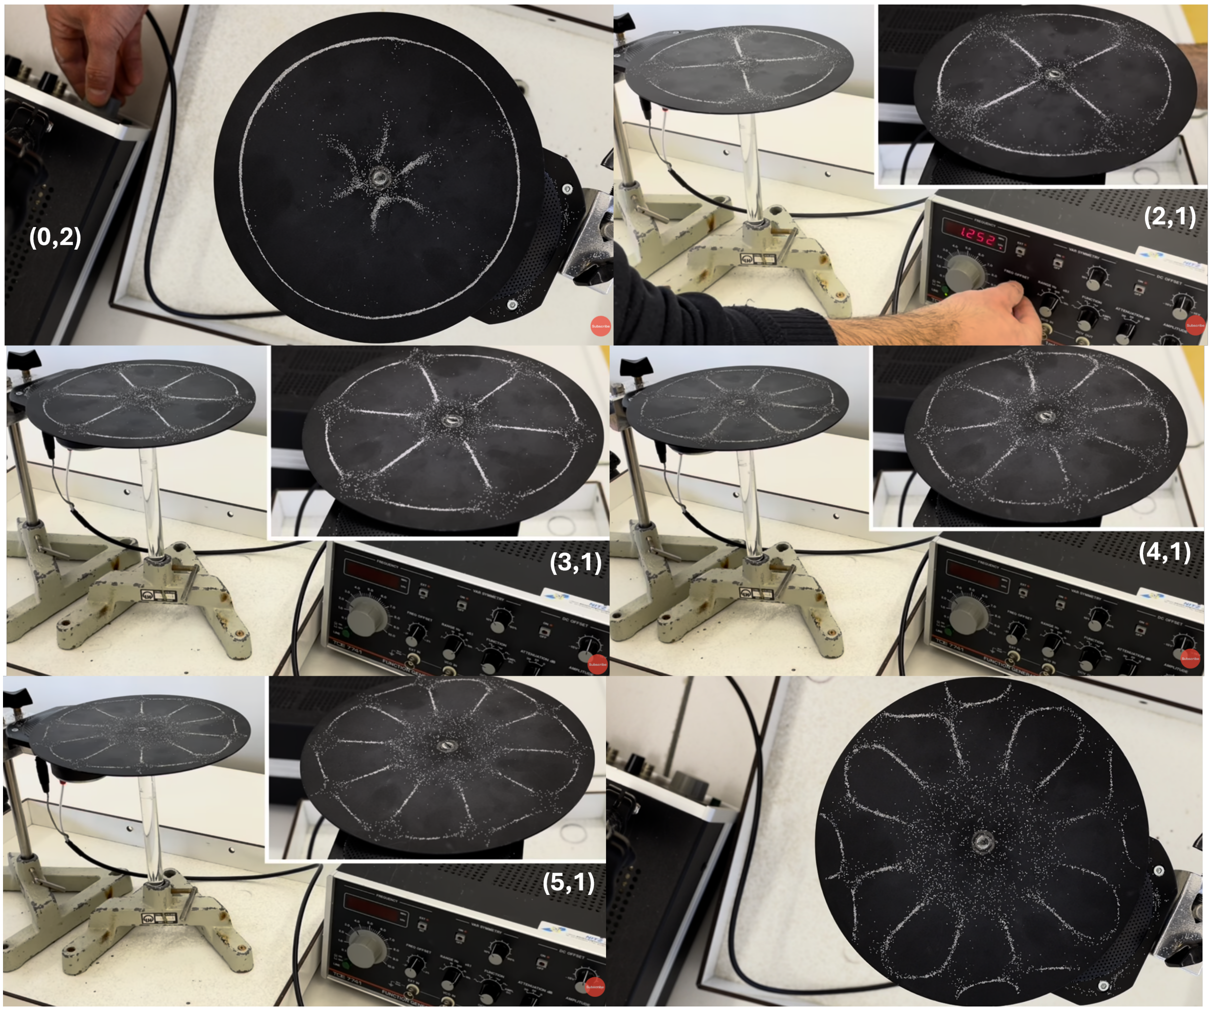

Figure 9.121: **Circular Chladni plate (source: YouTube, author: Labtastic)**

9.4.6 Phasors

There are several ways of expressing the wave functions that we have seen previously. Physicists (as well as electrotechnicians and engineers) use a formulation, named a "phasor" or "Fresnel representation", which simplify of the writing of equation and thus greatly simplifies the study of complex (or simple) problems. Phasors use the properties of complex numbers to express trigonometric wave functions in a simplified form in all phenomena where oscillations occur.

What we name "phasor" is a function f whose value is complex and which, in a space with 1 dimension, is written:

$$f(x,t)=e^{\mathrm{i}(kx-\omega t)} \tag{9.4.176}$$

In all physics applications, t is the time variable.

Since this function is in $\mathbb{C}$, it has a real part that we will denote by g and an imaginary part that we will denote by h. Their identification is easy since, as we have already proved it in our study of complex numbers (see section Numbers page 243):

$$f(x,t)=\cos(kx-\omega t)+\mathrm{i}\sin(kx-\omega t) \tag{9.4.177}$$

Therefore the real and imaginary part are obviously given by:

$$\begin{aligned}g(x,t)&=\Re(f)=\cos(kx-\omega t)\\ h(x,t)&=\Im(f)=\sin(kx-\omega t)\end{aligned} \tag{9.4.178}$$

The module of f is easily computed by calculating:

$$|f|=f\cdot\bar{f}=\cos^2(kx-\omega t)+\sin^2(kx-\omega t)=1 \tag{9.4.179}$$

The real and imaginary parts vary when the position or time varies. The modulus does not change, it is always equal to 1. The change is manifested simply by the simple variation of angle that makes the vector representing f in the complex plane. This is a sufficient reason to speak of a phaser, since the variation of f can be visualized as a simple change of angle or phase.

If we are in a physical space with more than one dimension, say 3, then the expression for f becomes:

$$\boxed{f(\vec{r},t)=e^{\mathrm{i}(\vec{k}\circ\vec{r}-\omega t)}=\cos(\vec{k}\circ\vec{r}-\omega t)+\mathrm{i}\sin(\vec{k}\circ\vec{r}-\omega t)} \tag{9.4.180}$$

The situation is a little more difficult to visualize (...). It is the same as in one dimension, but here everything happens along a direction defined in 3D space by the wave vector $\vec{k}$. Specifically, we will have:

$$\begin{aligned}\cos(\vec{k}\circ\vec{r}-\omega t)&=\cos(k_xx+k_yy+k_zz-\omega t)\\ \sin(\vec{k}\circ\vec{r}-\omega t)&=\sin(k_xx+k_yy+k_zz-\omega t)\end{aligned} \tag{9.4.181}$$

The variation in time remains the same as in the one spatial dimension case but a displacement in space is a little more complicated than in the one dimension case. Here, any spatial displacement in a direction that is not orthonormal to $\vec{k}$ will cause the scalar product to change so that the argument f will vary. Here it is not only the magnitude or the norm of the wave vector $\vec{k}$ which gives the rate of variation of f under a spatial displacement but also the angle that this displacement makes with respect to the direction of $\vec{k}$ since we have an argument that varies as $\vec{k}\circ\vec{r}$ and therefore depends on this angle denoted here φ. Indeed, we have:

$$\vec{k}\circ\vec{r}=\|\vec{k}\|\cdot\|\vec{r}\|\cos(\varphi) \qquad (9.4.182)$$

The quantity $\vec{k}$ is often referred to as the "wave vector". Physically it is most often connected to the equivalent of the (linear) momentum of the wave for which it is obvious that the usual definition of the momentum ($p=mv$) no longer makes sense.

An important part of the systems studied in physics can not be characterized by a point and therefore described by a trajectory. A wave, an elastic band that oscillate do not have a single defined position, they are "continuous medium" over a certain interval. The question we ask ourselves in our attempt to describe them is rather how to describe the displacement of this medium in space and time. For example, for a wave, if we freeze time, how does the amplitude A of this wave vary from one place to another in space? We can also freeze space by looking at one place and ask how the amplitude varies with time?

The space coordinates and time now play a similar role as independent parameters. We measure the amplitude of the phenomenon at any time and in any place. We will therefore seek to obtain an expression of the type:

$$A=A(x,t) \qquad \text{or} \qquad A=A(\vec{r},t) \qquad (9.4.183)$$

in one or three dimensions.

The important point is that we seek to express A, whose correct name is a "field", as a function of time and space coordinates. For example, if the wave is very regular perhaps is it adequately described by $A\sim\cos(\omega t)$ if we look at a single place and by $A\sim\cos(kx)$ if we are able to fix the time?

The quantity ω will characterize the frequency of the variation of the same phenomenon. The name "angular frequency" is easy to understand since the cosine or sine function cycles if its argument changes of 2π over a time of one period $\Delta t=T$.

Let us recall that:

$$T\omega=2\pi\Rightarrow\omega=\frac{2\pi}{T}=2\pi\nu \qquad (9.4.184)$$

In the description of harmonic systems (in Wave Mechanics, Quantum Physics or Quantum Chemistry), the phasor notation can be very useful as we have already said. The equation the most often encountered is the wave equation (which we proved at the beginning of this section). In one dimension, it is written for recall as:

$$\frac{\partial^2}{\partial x^2}A(x,t)-\frac{1}{v}\frac{\partial^2}{\partial t^2}A(x,t)=0 \qquad (9.4.185)$$

We check by simple substitution that some particular solutions are of the type:

$$A(x,t)=A_0\sin(kx-\omega t) \qquad \text{or} \qquad A(x,t)=A_0\cos(kx-\omega t) \qquad (9.4.186)$$

or a linear combination of which the most general form is:

$$A(x,t)=A_0\cos(kx-\omega t)+A_0\sin(kx-\omega t) \tag{9.4.187}$$

A quick and effective way of writing all these relations in a condensed and usefully pictorial way is to write:

$$\boxed{A(x,t)=A_0e^{\mathrm{i}(kx-\omega t)}} \tag{9.4.188}$$

In all three cases, the substitution makes it possible to verify it (the differential equation). Let us take, for example, the sinus solution. Therefore:

$$\begin{aligned}&A(x,t)=A_0\sin(kx-\omega t)\\&\Rightarrow\frac{\partial A}{\partial x}=kA_0\cos(kx-\omega t)\Rightarrow\frac{\partial^2 A}{\partial x^2}=-k^2A_0\sin(kx-\omega t)\\&\Rightarrow\frac{\partial A}{\partial t}=-\omega A_0\cos(kx-\omega t)\Rightarrow\frac{\partial^2 A}{\partial t^2}=-\omega^2A_0\sin(kx-\omega t)\end{aligned} \tag{9.4.189}$$

The replacement in the equation gives:

$$\left(-k^2+\frac{\omega^2}{\nu^2}\right)A_0\sin(kx-\omega t)=0 \tag{9.4.190}$$

Which will be satisfied if and only if:

$$\boxed{k^2=\frac{\omega^2}{v^2}\Leftrightarrow\omega^2=k^2v^2} \tag{9.4.191}$$

The substitution of the phasor as a solution of the wave equation transforms this last differential equation into a simple algebraic equation $\omega=\omega(k)$ named "dispersion relation". This relation is obviously characteristic of the equation that generates it. That which appears above is particularly simple and characterizes a free wave in a non-dispersive medium, as described by the wave equation that we have written.

The phasor solution:

$$A(x,t)=A_0e^{\mathrm{i}(kx-\omega t)} \tag{9.4.192}$$

therefore also satisfies the wave equation, with the same dispersion relation. Is it then also the description of a wave? The answer is YES, and even twice rather than one, as we will see below.

A physical wave is obviously not complex (at least in Classical Mechanics). The phasor solution is complex and therefore has a real part and an imaginary part. We show here that each of the two parts can represent a general real wave. Let us use a more general starting point. Let us assume that the amplitude A_0 is itself a complex number! We can therefore write:

$$A_0=|A_0|e^{\mathrm{i}\delta} \tag{9.4.193}$$

Therefore we have:

$$A(x,t)=A_0e^{\mathrm{i}(kx-\omega t+\delta)}=A_0(\cos(kx-\omega t+\delta)+\mathrm{i}\sin(kx-\omega t+\delta)) \tag{9.4.194}$$

We first study the real part of this expression and using trigonometric identities (see section Trigonometry page 2519):

$$\begin{aligned}\Re(A(x,t))=A_0\cos(kx-\omega t+\delta)&=A_0[\cos(kx-\omega t)\cos(\delta)-\sin(kx-\omega t)\sin(\delta)]\\&=A_0\cos\delta\cos(kx-\omega t)-A_0\sin\delta\sin(kx-\omega t)\end{aligned}\tag{9.4.195}$$

This real part is therefore of the most general (and real) form of the monochromatic solution for the wave equation, namely:

$$A(x,t)=A_1\cos(kx-\omega t)+A_2\sin(kx-\omega t)\tag{9.4.196}$$

Clearly, it is sufficient to identify:

$$\left.\begin{aligned}A_0\cos(\delta)&=A_1\\-A_0\sin(\delta)&=A_2\end{aligned}\right\}=\begin{cases}A_0=\sqrt{A_1^2+A_2^2}\\ \delta=-\arctan(A_2/A_1)\end{cases}\tag{9.4.197}$$

which connect two parameters to two others. The real part of the phasor is therefore sufficient to fully describe the monochromatic wave.

We can do exactly the same thing with the imaginary part of the phasor and prove in an identical way that it is sufficient to describe the monochromatic wave entirely.

The conclusions is that it is therefore possible to use the phasor to do all the mathematical manipulations required by the physical problem and in the end, to keep only the real or imaginary part, according to what was agreed from the beginning.

As we have already said, the most simple general real form of the solution is:

$$A(x,t)=A_1\sin(kx-\omega t)+A_2\cos(kx-\omega t)\tag{9.4.198}$$

This function has the behaviour of a sine (or a cosine) whose amplitude is given by:

$$A_0^2=A_1^2+A_2^2=(A_0\cos(\delta))^2+(-A_0\sin(\delta))^2\tag{9.4.199}$$

Moreover, the initial conditions adjust A_2 such that, at $x=0$ and $t=0$ (initially), the field $A(x,t)$ has the value A_2 therefore. These two conditions set these two parameters. We could have used the equally general form:

$$A(x,t)=A_0\sin(kx-\omega t+\delta)\tag{9.4.200}$$

Here the known amplitude is A_0 and the initial conditions are such that at $x=0$ and $t=0$, the field has the value:

$$A(x,t)=A_0\sin(\delta)\tag{9.4.201}$$

Again, two conditions set two parameters!

The amplitude is an obvious thing, the phase a little less. For a function of the type:

$$A(x,t)=A_0\sin(\arg+\delta)\tag{9.4.202}$$

has any value that one wants when its arg (argument) is, say zero, it suffices to adjust the value of the phase δ. It is like dragging the sinusoidal function along the x-axis, so as to satisfy the initial physical conditions imposed by the system studied.

Of two functions of the sine or cosine type that do not start at the same point in their cycle, we say that they are "out of phase". This becomes vital when there is more than one wave present. Let us imagine the simplest case of two waves of the same amplitude:

$$\begin{aligned}A_1(x,t)&=A_0\sin(\theta+\delta_1)\\A_2(x,t)&=A_0\sin(\theta+\delta_2)\end{aligned}\qquad(9.4.203)$$

Here the argument (θ) is a variable and the phases δ_1 and δ_2 the constant parameters. We consider the physical result of the wave resulting from the addition of these two waves.

If $\delta_2-\delta_1=2k\pi$ for $k\in\mathbb{Z}$ the resulting wave will be a sinusoidal wave of amplitude 2 times A_0. However, if $\delta_2-\delta_1=k\pi\;\;k\in\mathbb{Z}$ the resulting wave will be identically zero everywhere. The difference is therefore considerable and we can produce all intermediate situations! It is therefore important to keep in mind the phase at the origin of the wave or better, its relative phase in relation to other waves of our physical system!

In the phasor, either the real part or the imaginary part, is sufficient to give a general description of the wave (always monochromatic up to now). They are respectively composed of a cosine and a sinus and therefore phase-shifted of $\pi/2$ with respect to each other!

It is desirable to return to the "dispersion relation" that we had obtained. We have seen that for the free monochromatic wave, that which is a solution of the homogeneous wave equation, this relation is written so that the phase of the solution corresponds to this reality:

$$\omega^2=k^2v^2\Rightarrow\omega=\omega(k)\Leftrightarrow k=k(\omega)\qquad(9.4.204)$$

Still in the free case, we can have a physical situation that corresponds to the addition of several free monochromatic waves. The result is not monochromatic and is obviously written as a sum:

$$A(x,t)=\sum_n A_n(x,t)=\sum_n A_n e^{\mathrm{i}(k_nx-\omega_nt+\delta_n)}\qquad(9.4.205)$$

We often name it "wave packet" for obvious reasons (we will use this concept again in the section of Wave Quantum Physics). Since everything is free, each component will satisfy:

$$\omega_n^2=k_n^2v_n^2\qquad(9.4.206)$$

In a non-dispersive wave medium, waves can propagate without deformation. Electromagnetic waves in unbounded free space are non-dispersive as well as non-dissipative and thus can propagate over astronomical distances. Sound waves in air are also nearly non-dispersive even in the ultrasonic frequency range. If not, that is, if high frequency notes (e.g., piccolo) and low frequency notes (e.g., base) propagate at different velocities, they would reach our ears at different times, and music played by an orchestra would not be harmonious. Most waves in material media are dispersive, however, and wave forms originally set up are bound to change in a manner that the wave energy is more spatially spread out or dispersed.

In practice we consider four situation (we give also the Maple™ 4.00b code that permits the user to see the animation by themselves as it is very important for a good a deep comprehension):

- Dispersive wavepacket where the waves in the packet oscillates and the packet becomes larger and larger (we strongly recommend to the reader to change the maximum values of `x` and `t`):

  ```
  >with(plots):
  >animate(sum(.07*(exp(-(.1*k-3)^2)+exp(-(0.1*k+3)^2))*cos(.1*k*x-.1*k/
  sqrt(1+.1*(.1*k)^2)*t),k=1..100),x=-4..60,t=0..100,frames=60,numpoints=200,
  color=red);
  ```

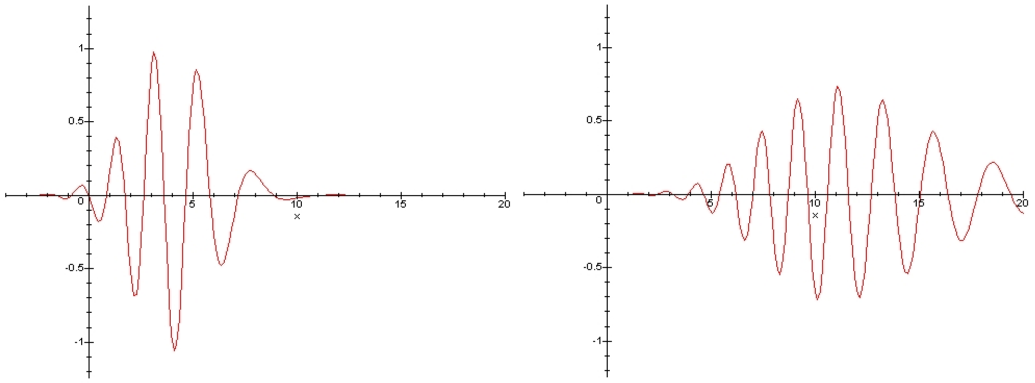

Figure 9.122: **Dispersive Wavepacket in Maple™ 4.00b**

- Non-dispersive wavepacket where the waves in the packet don't oscillates and the packet conserve the same width:

  ```
  >with(plots):
  >animate(sum(.07*(exp(-(.1*k-3)^2)+exp(-(0.1*k+3)^2))*cos(.1*k*x-.1*k/
  sqrt(1+.0*(.1*k)^2)*t),k=1..100),x=-4..20,t=0..30,frames=60,numpoints=200,
  color=red);
  ```

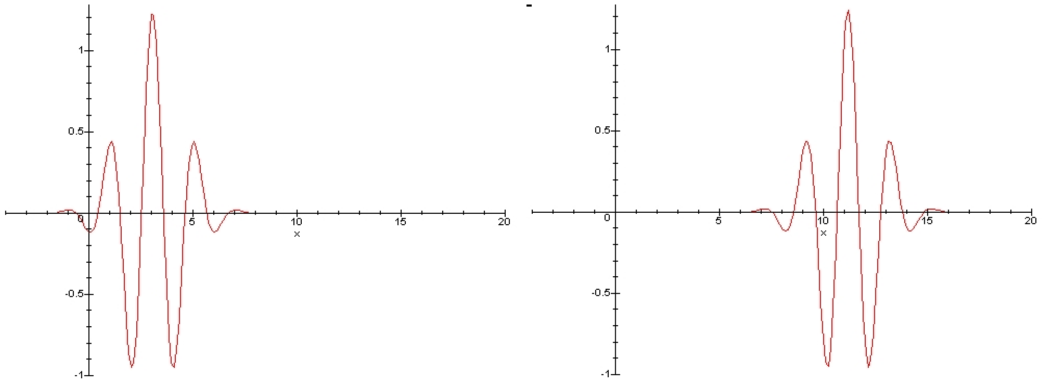

Figure 9.123: **Non-dispersive Wavepacket in Maple™ 4.00b**

- Dispersive sinusoidal wave where we have multiple wavepackets that oscillates in each of the wavepackets and their width doesn't change:

  ```
  >with(plots):
  >animate(sin(x-t)+sin(1.2*x-1.1*t),x=0..50,t=0..63,numpoints=150,
  frames=100,color=red);
  ```

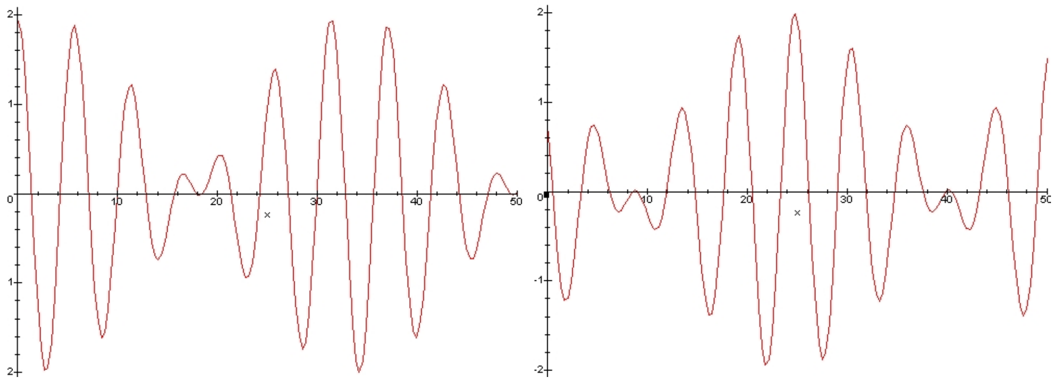

Figure 9.124: **Dispersive sinusoidal waves with Maple™ 4.00b**

- Non-dispersive sinusoidal wave where we have multiple wavepackets where the waves in the packet don't oscillates and their width doesn't change:

  ```
  >with(plots):
  >animate(sin(x-t)+sin(1.2*x-1.2*t),x=0..50,t=0..63,numpoints=150,
  frames=100,color=red);
  ```

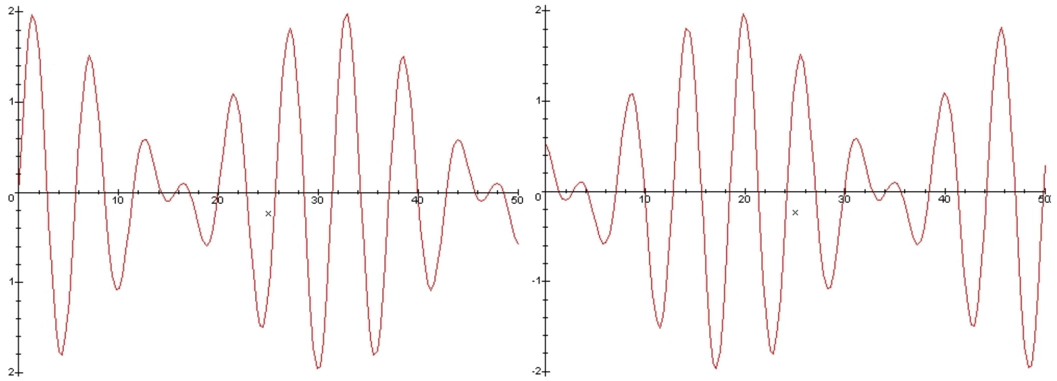

Figure 9.125: **Non-dispersive sinusoidal waves with Maple™ 4.00b**

Here we will notice two things for the free-wave equation:

1. First, even for free waves, it is quadratic, so we can change the sign of the wave vector and / or the pulsation without affecting the equation. We observe trivially that for one or more components of the positive wave vector the wave propagates towards the x-crescents for these positive components and that conversely for one or more negative components the wave propagates towards the x decreasing. Similarly, a negative or positive pulsation means that time varies towards the past or the future.

2. On the other hand, certain types of waves do not obey an equation as simple as the homogeneous above. This is the case for water waves, for example, both because of the nature of the liquid in which they propagate and because of the gravitational recall force. Sometimes, too, a wave that would be totally free, or nearly so, seeks to propagate itself in an environment where the conditions of propagation are seriously affected. For example a sound wave that tries to spread in the mastic or an electromagnetic wave that seeks to propagate in a conductor (a metal). In this case, a large part of the difference between free wave and modified wave by the medium can be described by a change of the dispersion.

9.4.7 Superposition of periodic waves

The superposition of periodic waves is a very common case in electrodynamics, electronics, acoustics and marine engineering. In order not to repeat this study in each of the previously mentioned corresponding sections of this textbook, it seemed more appropriate to us to put all information needed here below.

We will therefore focus on a particular case in order to see the intellectual approach. However, with computers, these calculations by hand have become somewhat obsolete. They must nevertheless be part of the general culture of the engineer or physicist.

Let us first consider two periodic (harmonic) signals generated at the same point of the type:

$$y_1 = A_1 \sin(\phi_1 - \omega_1 t) \quad \text{and} \quad y_2 = A_2 \sin(\phi_2 - \omega_2 t) \tag{9.4.207}$$

For pedagogical reasons, we noticed that it was better to work without phasers. So we will try to make a minimal use of them but for the beginning it will be indispensable. Indeed, the two waves and their sum can be represented in the Gauss plane (see section Numbers page 244) in the following form:

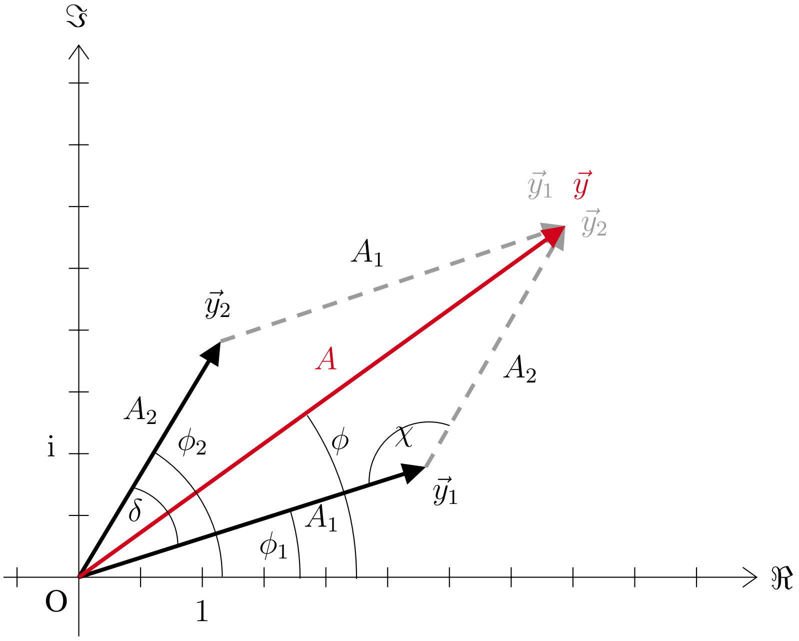

Figure 9.126: **Phase representation of the two harmonics in the Gauss plane**

wither therefore:

$$y = y_1 + y_2 = A_1 \sin(\phi_1 - \omega_1 t) + A_2 \sin(\phi_2 - \omega_2 t) \tag{9.4.208}$$

The amplitude of the sum of the two signals is easily obtained by applying the cosine theorem (see section Trigonometry page 2524). So let us first observe that since we are dealing with a parallelogram, we have (see section Geometric Shapes page 2908):

$$\chi = \pi - \delta \tag{9.4.209}$$

Therefore it comes:

$$A^2 = A_1^2 + A_2^2 - 2A_1A_2\cos(\pi - \delta) = A_1^2 + A_2^2 + 2A_1A_2\cos(\delta) \qquad (9.4.210)$$

hence:

$$A = \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos(\delta)} \qquad (9.4.211)$$

The term $2A_1A_2\cos(\delta)$ is named the "correlation term". As the phasors are rotating, we have in reality:

$$\delta = (\phi_2 - \omega_2 t) - (\phi_1 - \omega_1 t) = \phi_2 - \phi_1 - (\omega_2 - \omega_1)t \qquad (9.4.212)$$

The phase ϕ of the sum of the waves is obtained simply by doing in the elementary trigonometry in the previous figure:

$$\tan\phi = \frac{A\sin\phi}{A\cos\phi} = \frac{A_1\sin(\phi_1 - \omega_1 t) + A_2\sin(\phi_2 - \omega_2 t)}{A_1\cos(\phi_1 - \omega_1 t) + A_2\cos(\phi_2 - \omega_2 t)} \qquad (9.4.213)$$

Now, let us consider the particular case where the two waves are in phase:

$$\phi_1 = \phi_2 = \pi \qquad (9.4.214)$$

It then comes (see section Trigonometry page 2513):

$$y_1 = A_1\sin(\phi_1 - \omega_1 t) = A_1\sin(\omega_1 t) \quad \text{and} \quad y_2 = A_2\sin(\phi_2 - \omega_2 t) = A_2\sin(\omega_2 t) \qquad (9.4.215)$$

and the amplitude is then written:

$$\begin{aligned} A &= \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos(\phi_2 - \phi_1 - (\omega_2 - \omega_1)t)} \\ &= \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos(-(\omega_2 - \omega_1)t)} = \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos((\omega_2 - \omega_1)t)} \\ &= \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos(\Delta\omega t)} \end{aligned} \qquad (9.4.216)$$

So the amplitude will have two extremums:

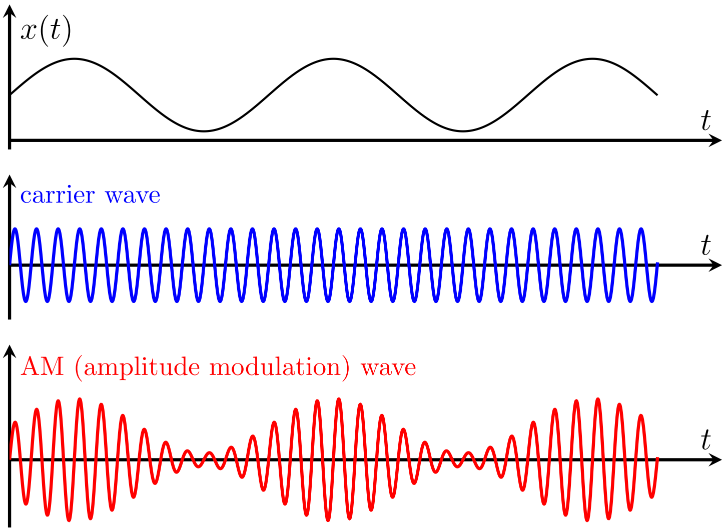
$$\begin{aligned} A_{min} &= \sqrt{A_1^2 + A_2^2 - 2A_1A_2} = \sqrt{(A_1 - A_2)^2} = |A_1 - A_2| \\ A_{max} &= \sqrt{A_1^2 + A_2^2 + 2A_1A_2} = \sqrt{(A_1 + A_2)^2} = A_1 + A_2 \end{aligned} \qquad (9.4.217)$$

Hence:

$$|A_1 - A_2| \leq A \leq A_1 + A_2 \qquad (9.4.218)$$

We then speak in the field of electrodynamics, and of acoustics of "amplitude modulation". The "modulation frequency", also named "beat frequency" is then:

$$f_m = \frac{|\omega_1 - \omega_2|}{2\pi} = |f_2 - f_1| \qquad (9.4.219)$$



$x(t)$
t
carrier wave
t
AM (amplitude modulation) wave
t

Figure 9.127: **Amplitude modulation (AM) illustrated**

Let us also see an example with Maple™ 4.00b (superimposition of a Bemol Si and of a Do with an intensity ratio of 0.8):

```
>A:=1;B:=0.8;f1:=466.16;f2:=523;w1:=2*Pi*f1;w2:=2*Pi*f2;
>plot(A*sin(w1*t)+B*sin(w2*t),t=0..0.05);
```

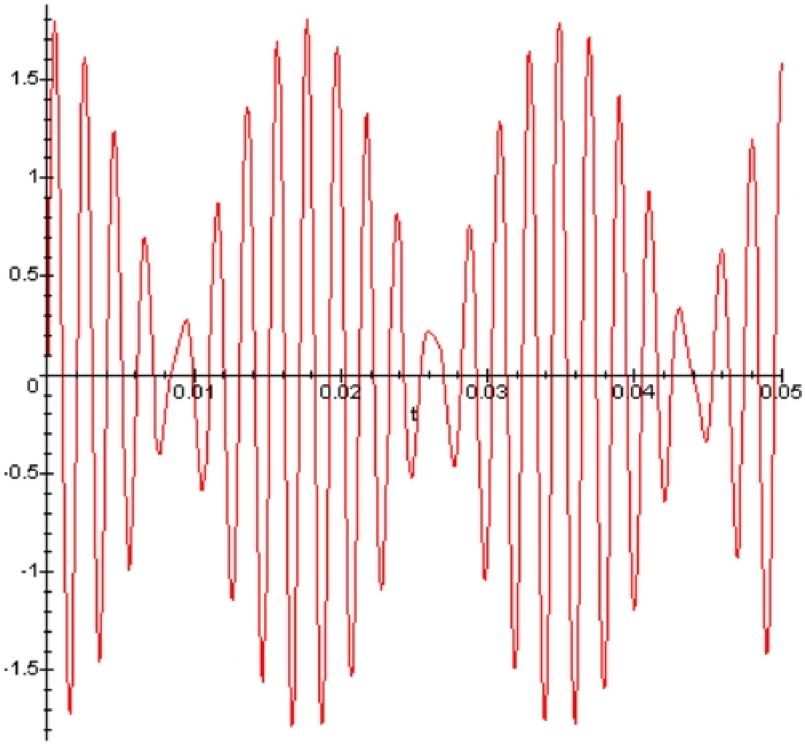


Figure 9.128: **Representation of the amplitude modulation with Maple™ 4.00b**

And if we add the envelope:

```
>plot([A*sin(w1*t)+B*sin(w2*t),sqrt(A^2+B^2+2*A*B*cos((w2-w1)*t))],t=0..0.05);
```

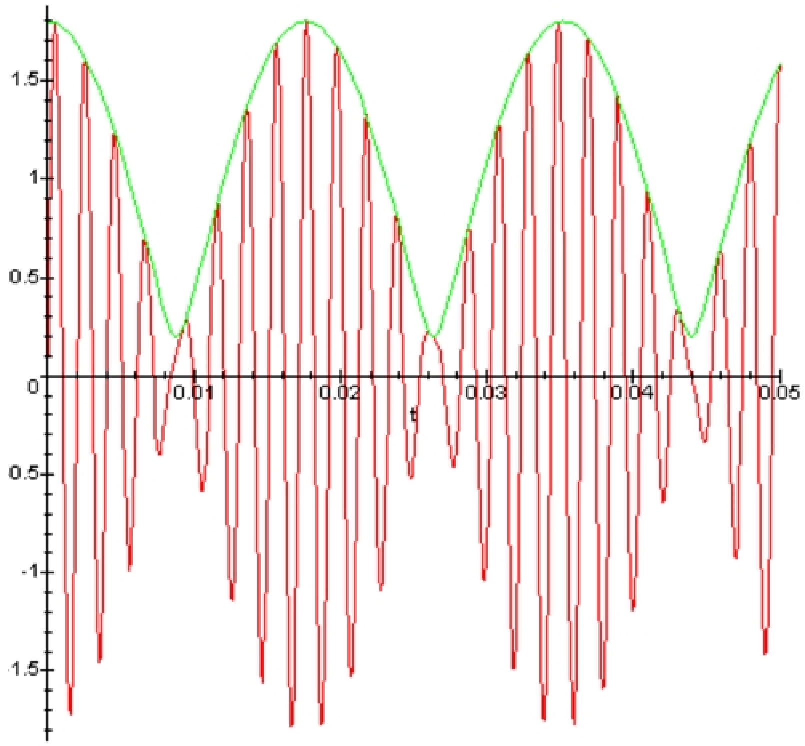

Figure 9.129: **Representation of the envelope of the amplitude modulation with Maple™ 4.00b**

In the general case, it is difficult to simplify the expression of the resulting signal:

$$y=y_1+y_2=A_1\sin(\omega_1 t)+A_2\sin(\omega_2 t) \tag{9.4.220}$$

If the amplitudes are identical $A_2=A_1$ then we have:

$$y=A_1(\sin(\omega_1 t)+\sin(\omega_2 t)) \tag{9.4.221}$$

And thus using one of the Simpson formulas proved in the section of Trigonometry, it comes:

$$y=\underbrace{2A_1\cos\left(\left(\frac{\omega_1-\omega_2}{2}\right)t\right)}_{:=A}\sin\left(\left(\frac{\omega_1+\omega_2}{2}\right)t\right)=A\sin\left(\left(\frac{\omega_1+\omega_2}{2}\right)t\right) \tag{9.4.222}$$

Moreover, if the two frequencies are close, we have:

$$\begin{aligned}y&=2A_1\cos\left(\left(\frac{\omega_1-\omega_2}{2}\right)t\right)\sin\left(\left(\frac{\omega_1+\omega_2}{2}\right)t\right)=2A_1\cos(0)\sin\left(\left(\frac{2\omega_1}{2}\right)t\right)\\&=2A_1\sin(\omega_1 t)\end{aligned} \tag{9.4.223}$$

Now, let consider the case where the waves advance (because until now they were stationary):

$$y=y_1+y_2=A_1\sin(k_1 r-\omega_1 t)+A_2\sin(k_2 r-\omega_2 t) \tag{9.4.224}$$

If the two amplitudes are identical, we have:

$$y=A_1(\sin(k_1 r-\omega_1 t)+\sin(k_2 r-\omega_2 t)) \tag{9.4.225}$$

Using Simpson's formula again, it comes:

$$\begin{aligned}y&=2A_1\cos\left(\frac{(k_1r-\omega_1t)-(k_2r-\omega_2t)}{2}\right)\sin\left(\frac{(k_1r-\omega_1t)+(k_2r-\omega_2t)}{2}t\right)\\&=2A_1\cos\left(-\frac{(k_1r-\omega_1t)-(k_2r-\omega_2t)}{2}\right)\sin\left(\frac{(k_1r-\omega_1t)+(k_2r-\omega_2t)}{2}t\right)\\&=2A_1\cos\left(\left(\frac{k_2-k_1}{2}\right)r-\left(\frac{\omega_2-\omega_1}{2}\right)t\right)\sin\left(\left(\frac{k_2+k_1}{2}\right)r-\left(\frac{\omega_2+\omega_1}{2}\right)t\right)\\&=2A_1\cos\left(\frac{\Delta k}{2}r-\frac{\Delta\omega}{2}t\right)\sin\left(\left(\frac{k_2+k_1}{2}\right)r-\left(\frac{\omega_2+\omega_1}{2}\right)t\right)\end{aligned}\tag{9.4.226}$$

Therefore the amplitude is modulated according to the term:

$$2A_1\cos\left(\frac{\Delta k}{2}r-\frac{\Delta\omega}{2}t\right)\tag{9.4.227}$$

The amplitude is thus described by a wave function. The corresponding wave represents the progression of a carrier wave packet, progressing at the speed:

$$v=\frac{\Delta\omega}{\Delta k}\tag{9.4.228}$$

We also notice that if we have the two progressive waves of direction of opposite propagation such as:

$$k_2=-k_1\tag{9.4.229}$$

then:

$$\begin{aligned}y&=2A_1\cos\left(\frac{\Delta k}{2}r-\frac{\Delta\omega}{2}t\right)\sin\left(\left(\frac{k_2+k_1}{2}\right)r-\left(\frac{\omega_2+\omega_1}{2}\right)t\right)\\&=2A_1\cos\left(k_1r-\frac{\Delta\omega}{2}t\right)\sin\left(\left(\frac{\omega_2+\omega_1}{2}\right)t\right)\end{aligned}\tag{9.4.230}$$

If in addition the two harmonics are synchronous (of the same frequency), then we have:

$$y=2A_1\cos\left(k_1r-\frac{\Delta\omega}{2}t\right)\sin\left(\left(\frac{\omega_2+\omega_1}{2}\right)t\right)=2A_1\cos(k_1r)\sin(\omega_1t)\tag{9.4.231}$$

It is therefore a stationary wave but whose amplitude is modulated as a function of time and position. Indeed the reader will notice that at several points r the wave is always zero.

Now let us consider a system of loudspeakers (TV, stereo, etc.) that emit acoustic waves synchronously with the same amplitude and frequency. Since the source of the two harmonics is not reduced to a single point, we have in function of our distance r_1 the first loudspeaker and the of the second r_2:

$$y=A(\sin(kr_1-\omega t)+\sin(kr_2-\omega t))\tag{9.4.232}$$

Applying Simpson's formula again, it comes:

$$\begin{aligned}y&=2A\cos\left(\frac{(kr_1-\omega t)-(kr_2-\omega t)}{2}\right)\sin\left(\frac{(kr_1-\omega t)+(kr_2-\omega t)}{2}t\right)\\&=2A\cos\left(\frac{k(r_1-r_2)}{2}\right)\sin\left(\frac{k(r_1+r_2)}{2}-\omega t\right)\end{aligned}\tag{9.4.233}$$

If we are equal distance from the two loudspeaker, it comes:

$$y=2A\sin(kr-\omega t) \tag{9.4.234}$$

Thus the amplitude is there maximal ("constructive interference") and is twice the amplitude of each harmonic. In fact, we find maxima of amplitude at each point where:

$$\cos\left(\frac{k(r_1-r_2)}{2}\right)=\pm 1 \tag{9.4.235}$$

thus:

$$\frac{k(r_1-r_2)}{2}=n\pi\Rightarrow r_1-r_2=\frac{2n\pi}{k}=\frac{2n\pi}{\frac{\omega}{v_{\text{phase}}}}=\frac{2n\pi v_{\text{phase}}}{2\pi f}=n\frac{v_{\text{phase}}}{f} \tag{9.4.236}$$

where n is a relative integer (possibly equal to zero!). So, exactly between the two loudspeakers, we find a maxima. For a same n, all the values of r_1, r_2 that satisfy this relation are named "ventral lines".

We have in extenso the amplitude which is zero ("destructive interference") whenever:

$$\cos\left(\frac{k(r_1-r_2)}{2}\right)=0 \tag{9.4.237}$$

Thus:

$$\frac{k(r_1-r_2)}{2}=n\frac{\pi}{2}\Rightarrow r_1-r_2=\frac{n\pi}{k}=\frac{n\pi}{\frac{\omega}{v_{\text{phase}}}}=\frac{n\pi v_{\text{phase}}}{2\pi f}=n\frac{v_{\text{phase}}}{\pi f} \tag{9.4.238}$$

where n is a non-zero relative odd integer. For the same n, all the values r_1, r_2 that satisfy this relation are named "nodal lines".

● Purely constructive - two crests
● Purely constructive - two troughs
● Purely destructive - one crest and one trough

Figure 9.130: Waves interferences of two loudspeakers (source: OpenStax)

There is also a simple elegant way to introduce the superposition principle. Suppose that the wavefunctions ψ_1 and ψ_2 are each separate solutions of the wave equation; it follows that $(\psi_1+\psi_2)$ is also a solution. This is known as the Superposition Principle, and it can easily be proven since it must be true that:

$$\frac{\partial^2\psi_1}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2\psi_1}{\partial t^2} \quad \text{and} \quad \frac{\partial^2\psi_2}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2\psi_2}{\partial t^2} \tag{9.4.239}$$

Adding these yields:

$$\frac{\partial^2\psi_1}{\partial x^2}+\frac{\partial^2\psi_2}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2\psi_1}{\partial t^2}+\frac{1}{v^2}\frac{\partial^2\psi_2}{\partial t^2} \tag{9.4.240}$$

and so:

$$\frac{\partial^2}{\partial x^2}(\psi_1+\psi_2)=\frac{1}{v^2}\frac{\partial^2}{\partial t^2}(\psi_1+\psi_2) \tag{9.4.241}$$

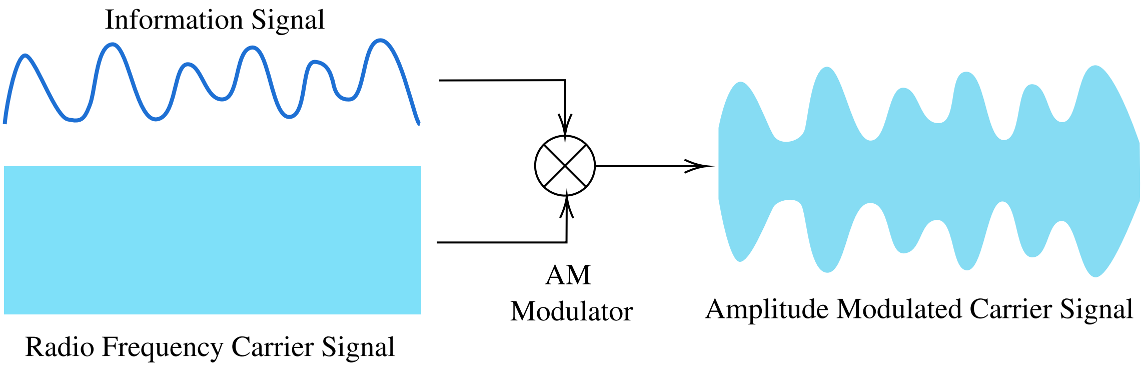
which establishes that $(\psi_1+\psi_2)$ is indeed a solution. What this means is that when two separate waves arrive at the same place in space wherein they overlap, they will simply add to (or subtract from) one another without permanently destroying or disrupting either wave. The resulting disturbance at each point in the region of overlap is the algebraic sum of the individual constituent waves at that location. Once having passed through the region where the two waves coexist, each will move out and away unaffected by the encounter.

9.4.7.1 AM/FM Broadcasting

In telecommunications and signal processing, frequency modulation (FM) is the encoding of information in a carrier wave by varying the instantaneous frequency of the wave. This contrasts with amplitude modulation, in which the amplitude of the carrier wave varies, while the frequency remains constant.

Before a radio station can begin broadcasting, the operator must first determine the frequency that best fits the information it wants to send, and then construct a suitable transmitter and antenna to cover the desired area over which the receivers will be located. Next, the station operator must determine how the information to be broadcast will be superimposed onto the chosen radio frequency. The process of superimposing information onto a radio frequency is named "modulation". There are many different modulation techniques available but the two most popular are "Amplitude Modulation (AM) and Frequency Modulation (FM).

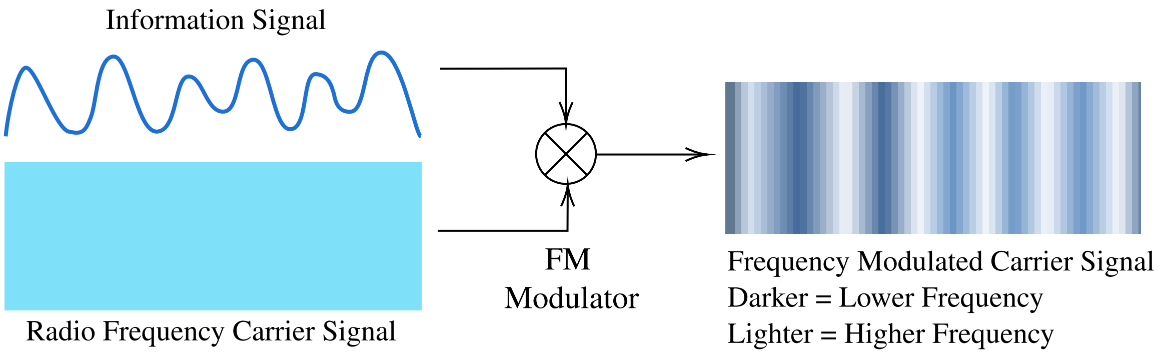
With "Amplitude Modulation", changes in the amplitude of the information signal causes a proportional change in the amplitude of the radio frequency signal (also referred to as a "carrier signal" as we know):



Information Signal
AM
Modulator
Amplitude Modulated Carrier Signal
Radio Frequency Carrier Signal

Figure 9.131: **AM modulation principle (source: netZener)**

With "Frequency Modulation", changes in the amplitude of the information signal causes a proportional shift in the frequency of the "carrier signal". The instantaneous frequency deviation, the difference between the frequency of the carrier and its center frequency, is proportional to the modulating signal.



Information Signal
FM
Modulator
Frequency Modulated Carrier Signal
Darker = Lower Frequency
Lighter = Higher Frequency
Radio Frequency Carrier Signal

Figure 9.132: **Waves interferences of two loudspeakers (source: netZener)**

Remark

FM radio is inherently less subject to noise from stray radio sources than AM radio. The reason is that amplitudes of waves add. So an AM receiver would interpret noise added onto the amplitude of its carrier wave as part of the information. A FM receiver can be made to reject amplitudes other than that of the basic carrier wave and only look for variations in frequency. It is thus easier to reject noise from FM, since noise produces a variation in amplitude.

We will study in the section of Electrical Engineering how is build a FM modulator!

9.5. Statistical Mechanics

STATISTICAL MECHANICS, also named sometimes "Statistical Thermodynamics" or more generally "Statistical Physics", aims to explain the behaviour of macroscopic systems (consisting of many interacting objects) from their microscopic characteristics using statistical and probabilistic tools. It is in a much more general way that quantum physics describes the properties and evolution of physical systems at the microscopic scale. Statistical Mechanics is therefore built on this quantum description as discussed on mathematical developments that will follow.

« *Ludwig Boltzmann, who spent much of his life studying statistical Mechanics, died in 11906 (holocene calendar), by his own hand. Paul Ehrenfest, carrying on the work, died similarly in 11933 (holocene calendar). Now it is our turn to study Statistical Mechanics.* » These are the opening sentences of an excellent textbook, *States of Matter* (11975), by David L. Goodstein.

The approach presented here is to address the basic Statistical Mechanics to then deduce the fundamentals of Thermodynamics. Statistical Mechanics is indeed with quantum physics and relativity, a cornerstone of modern physics in explaining phenomena from their constituents! It is important to perceive it immediately as a fundamental theory, and not as a mere attempt to justify retrospectively thermodynamics. Thermodynamics itself gains back more just and deeper understanding of its principles and methods.

9.5.1 Statistical Information Theory

The word "information" is used in very diverse contexts, in totally different sense following scientific disciplines: we can cite as an example thermodynamics with the concept of entropy, applied physics with the theory of signal, biology with the genome theory and quantum physics with the probability of getting information.

Definition (#9.5.453): "Information" is the reduction of uncertainty with a system (formally expressed as Shannon entropy as we will see further below), i.e. the decrease in the number of yes/no choices - measured in bits (binary digits) - required to specify the exact state of a system out of all possible.

In physics, information is deeply tied to the state of a system. A new state is equivalent to a new information! Therefore when a star explodes, it creates new atoms hence new information. When particles interact, they produce new states hence new information. When entropy increases, the number of possible microstates grows, hence new information. Similarly inf biological evolution random stochastic mutations introducing variations sometimes create information and sometimes destructs information.

This raises the question whether it is possible to construct a theory of information and if it is unique? Our approach here is not information as such, but the amount of information! When we talk about quantity and measurement, we think to the concept of content or value of information. The information science in purpose must feel concerned by this questioning. If we define the "infometrics" as the set of technical mathematical and statistical measures of information, we wish to have a sufficiently clear definition of the concept of quantity of information that can lead us to define a measure, that is to say a set of well-defined operations, bringing us to clear axioms and whose result is a number.

We are therefore concerned here with the foundations of the statistical information theory also known as "Shannon's theory". The Shannon formula that emerges is certainly one of the fundamental concepts of physics and statistics as it affects all the irreducible brick physics, finance and statistics: information!!

We will show (further below) that an isolated physical system has for most probable state the one that contains the more internal states and is therefore a fortiori the most unpredictable. The most improbable state is the one that is more predictable (concerns about emergence of life...). Therefore, since the unpredictability appears as an essential attribute of the information, we identify the quantitative measurement information to its improbability.

Thus, the amount of information denoted by $h(x)$ given by the realization of an event x of probability $P(x)$ is an increasing function f of its improbability $\dfrac{1}{P(x)}$ following the postulate that the most probable state is the one that is the less predictable:

$$\boxed{h(x)=f\left(\frac{1}{P(x)}\right)} \tag{9.5.1}$$

Moreover, the realization of two independent events x and y intuitively provides an amount of information which is the sum of their respective amounts of information. We have seen in the section of Probabilities that for two independent event we have:

$$P(x,y)=P(x)P(y) \tag{9.5.2}$$

That is to say we are looking for a function f such that :

$$h(x)=f\left(\frac{1}{P(x,y)}\right)=f\left(\frac{1}{P(x)P(y)}\right)=f\left(\frac{1}{P(x)}\right)+f\left(\frac{1}{P(y)}\right)=h(x)+h(y) \tag{9.5.3}$$

The logarithm function (see section Functional Analysis page 2284) is by its properties a natural candidate for f such that:

$$f=\lambda\log_{\alpha}\left(\frac{1}{P(\ldots)}\right) \tag{9.5.4}$$

where λ is obviously a positive number.

Remark

The choice of the base of the logarithm defines the information unit which is completely arbitrary. Thereafter, and unless otherwise specified, "log" will designate the logarithm in base α.

Thus, the "quantity of intrinsic information" of an event x could be therefore using the properties of the logarithm:

$$\boxed{h(x)=-\lambda\log\left(P(x)\right)} \tag{9.5.5}$$

And can be considered as a measure of uncertainty about the event, or as that of the information needed to resolve this uncertainty. Why people decided that this specific measure is what we should use is a good question, and not so obvious. Information theorists try to justify it axiomatically. That is, if we pick this measure, it obeys some nice properties we intuitively want it to obey. Properties like "we want this number of be higher for unlikely events" and "we want this number to be additive for independent events." This is why we get a minus sign and a log

Here is an example that motivates this definition:

✍**Example:**

Agree that knowing the realization of an event that has for probability $1/2$ give us 1 bit of information (think for example to the binary system). We now launch n coins and take knowledge of the result of the experience: we acquire n bits of information. The event in question had the probability $\left(\dfrac{1}{2}\right)^n$. Therefore the number of bits of information is if we chose $\alpha=2$ and $\lambda=1$:

$$h(x)=-\lambda\log\left(P(x)\right)=-\lambda\log_2\left(\left(\frac{1}{2}\right)^n\right)=-n\lambda\log_2\left(\frac{1}{2}\right)=-n\lambda\cdot(-1)=n \quad (9.5.6)$$

This is an example that motivates our choice.

Definitions (#9.5.454):

D1. We define the "intrinsic information by pair" of two events x and y of joint probability $P(x,y)$ (see section Probabilities page 480) by:

$$h(x,y)=-\lambda\log\left(P(x,y)\right) \quad (9.5.7)$$

D2. We define also the "conditional information" of x when y is known by (see section Probabilities page 485):

$$h(x/y)=-\lambda\log\left(P(x/y)\right) \quad (9.5.8)$$

which can therefore also be written (this is just a different way to note that we have already presented in the section of Probabilities):

$$h(x\,|\,y)=-\lambda\log\left(P(x\,|\,y)\right) \quad (9.5.9)$$

This is the amount of information remaining about x once y has been observed.

We have proved in the section of Probabilities that the Bayes' formula allows us to notice immediately that if x and y are independent :

$$h(x/y)=h(x) \quad (9.5.10)$$

This is consistent with common sense.

D3. We also need sometimes to measure the amount of information that a particular variable for example y brings on another for example x. This is particularly the case when we identify x as the selection of a signal applied to the input of a channel and y the corresponding observed output signal (analysis used in code correction error as seen in the section of Error-Correcting code).

Let $P(x)$ the probability that x has been emitted and $P(x/y)$ the a priori probability that x was emitted, given that y was received.

A measurement of this quantity of information, named "mutual information" is denoted by:

$$i(x,y)=\lambda\log\left(\frac{P(x/y)}{P(x)}\right) \quad (9.5.11)$$

It is the logarithmic measure of the increase in the probability of x (thus the decrease in its amount information) due to its conditioning y. We can check if it is coherent with two situations:

(a) If the data of y is equivalent to x (case of a perfect channel), it is equal to the intrinsic information $h(x)$:

$$i(x,y)=\lambda\log\left(\frac{P(x/y)}{P(x)}\right)=\lambda\log\left(\frac{1}{P(x)}\right)=-\lambda\log(P(x)) \tag{9.5.12}$$

(b) It is null if, conversely, x and y are independent.

$$i(x,y)=\lambda\log\left(\frac{P(x/y)}{P(x)}\right)=\lambda\log\left(\frac{P(x)}{P(x)}\right)=-\lambda\log(1)=0 \tag{9.5.13}$$

Obviously we have:

$$\begin{aligned}i(x,y)&=h(x)-h(x/y)=-\lambda\log\left(P(x)\right)-\left[-\lambda\log\left(P(x/y)\right)\right]\\&=\lambda\log\left(P(x/y)\right)-\lambda\log\left(P(x)\right)=\lambda\left(\log\left(P(x/y)\right)-\log\left(P(x)\right)\right)\\&=\lambda\log\left(\frac{P(x/y)}{P(x)}\right)\end{aligned} \tag{9.5.14}$$

In the same way we prove that:

$$i(x,y)=h(y)-h(y/x) \tag{9.5.15}$$

Remark

Notice that in general $h(x/y)\neq h(y/x)$.

And using the formula of compound probabilities (see section Probabilities page 486):

$$\begin{aligned}i(x,y)&=\lambda\log\left(\frac{P(x/y)}{P(x)}\right)=\lambda\log\left(\frac{\dfrac{P(x\cap y)}{P(Y)}}{P(x)}\right)=\lambda\log\left(\frac{P(x\cap y)}{P(x)P(y)}\right)\\&=\lambda\log\left(\frac{P(x,y)}{P(x)P(y)}\right)\end{aligned} \tag{9.5.16}$$

The latter equality justifying the term "mutual". While the intrinsic information is positive, mutual information can be negative. We will see that his average, much more important in practice, can not be negative.

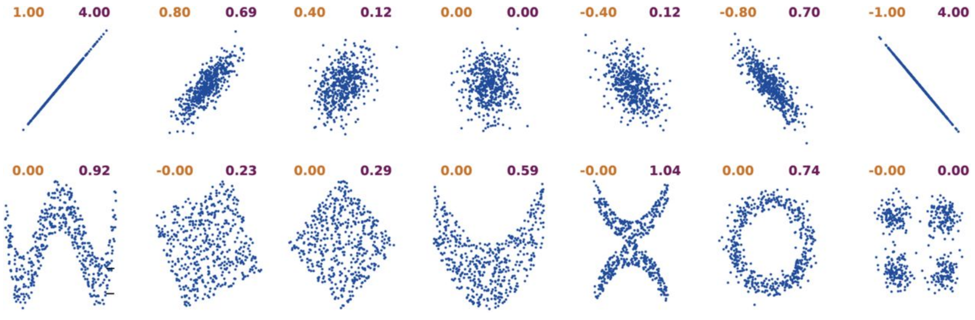

Figure 9.133: Examples of correlation vs mutual information.

> In the figure above, each panel illustrates a scatter plot of samples drawn from a particular bi-variate distribution. For each example, the correlation between the two variables is shown in orange (left) and the MI is shown in purple (right; discrete method, 16 bins, $100,000$ samples, no bias correction). The top row shows linear relationships, for which MI and correlation both detect a relationship (although on different scales, and note that as MI is always positive it does not reveal the direction of the relationship). The bottom row shows a series of distributions for which the correlation is zero.

The individual events are in general less important than the mean effect, we will consider them later as coming from a random source, discrete, finite, stationary, and white (i.e. independent successive events). The events are interpreted as choosing a symbol in the alphabet of the source. Let n be the size of the alphabet, and $x_1,\ldots,x_n$ its symbols. The source is therefore described by the random variable X, which takes values in the alphabet, with respective probabilities $p_1,\ldots p_n$, such as:

$$\sum_{i=1}^{n} P_i = 1 \qquad (9.5.17)$$

Definition (#9.5.455): The average amount of information from this source is the expected mean of the intrinsic information of each symbol of the alphabet of the source (see section Statistics page 634). We will name it "entropy" and denote it by $S(X)$ and given by the relation:

$$\boxed{S(X) = \mathrm{E}(h(x)) = -\lambda\sum_{i=1}^{n} P_i \log(P_i)} \qquad (9.5.18)$$

named "Shannon formula", or "Shannon entropy", and it is indeed a mean because its general expression for a discrete random variable is as we have seen in the section Statistics given by:

$$\mathrm{E}(X) = \sum_{i=1}^{n} P_i x_i \qquad (9.5.19)$$

but with in this case:

$$x_i = -\lambda\log(P_i) \qquad (9.5.20)$$

The reader can also notice that if the n events are of equal probabilities $1/n$ we have the famous relation:

$$S = -\lambda\sum_{i=1}^{n} P_i \log(P_i) = -\lambda\sum_{i=1}^{n}\frac{1}{n}\log\left(\frac{1}{n}\right) = -\lambda n\frac{1}{n}\log\left(\frac{1}{n}\right) = \log(n) \qquad (9.5.21)$$

Remark

For a business real application case of the Shannon formula you can see the subsection on the Diversity Index in the section of Statistics page 644.

However, the relation:

$$S(X) = \mathrm{E}(h(x)) = -\lambda\sum_{i=1}^{n} P_i \log(P_i) \qquad (9.5.22)$$

is an abuse of notation. Indeed, the expectation makes sense if $h(x)$ is a function of x. But in our case $h(x)$ does not depend on the values of x, but only to the associated probabilities. We will therefore sometimes more rigorously denote the entropy of a distribution by:

$$S(P_1,\ldots,P_n) \tag{9.5.23}$$

The "joint and conditional entropies" are defined in similar manner with the suitable notations:

$$S(X,Y)=\mathrm{E}(h(x,y))=-\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log(P(x_i,y_j)) \tag{9.5.24}$$

and (we adopt this time the symbol "|" instead of the "/" to indicate the conditional relation):

$$S(Y|X)=\mathrm{E}(h(y|x))=-\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log(P(y_j,x_i)) \tag{9.5.25}$$

The "mean mutual information", sometimes badly named "mutual information" is defined also directly:

$$I(X,Y)=\mathrm{E}(i(x,y))=\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log\left(\frac{P(x_i|y_j)}{P(x_i)}\right)=\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log\left(\frac{P(x_i,y_j)}{P(x_i)P(y_j)}\right) \tag{9.5.26}$$

Mutual information measures how much information - in the information-theoretic sense à a term an events contains about a class. If a term's distribution is the same in the class as it is en the collection as a whole, then $I(X,Y)=0$. Mutual information reaches its maximum value if the event is a perfect indicator for class membership, that is, if the term is present in a document if and only if the document is in the class.

Remark

The reader must notice that the definition of the amount of information, by a logarithmic measure may seem arbitrary, though reasonable, given the expected properties of such a measure. Shannon, and later Khintchine showed that taking into account certain properties putted as axioms laid the logarithmic function be the only one suitable choice.

✍**Example:**

Consider a classification of $N=801,948$ documents. We build the following contingency table according if they contain respectively the terms *poultry* and *export*:

	***Poultry* detected**	***Poultry* not detected**
***Export* detected**	$N_{11}=49$	$N_{10}=141$
***Export* not detected**	$N_{01}=27,652$	$N_{00}=774,106$

$$\begin{aligned}
I(X,Y)&=\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log\left(\frac{P(x_i|y_j)}{P(x_i)}\right)=\lambda\sum_{i=1}^{n}\sum_{j=1}^{m}P(x_i,y_j)\log\left(\frac{P(x_i,y_j)}{P(x_i)P(y_j)}\right)\\
&=\frac{N_{11}}{N}\log_2\left(\frac{\dfrac{N_{11}}{N}}{\dfrac{N_{1.}}{N}\dfrac{N_{.1}}{N}}\right)+\frac{N_{01}}{N}\log_2\left(\frac{\dfrac{N_{01}}{N}}{\dfrac{N_{0.}}{N}\dfrac{N_{.1}}{N}}\right)\\
&+\frac{N_{10}}{N}\log_2\left(\frac{\dfrac{N_{10}}{N}}{\dfrac{N_{1.}}{N}\dfrac{N_{.0}}{N}}\right)+\frac{N_{00}}{N}\log_2\left(\frac{\dfrac{N_{00}}{N}}{\dfrac{N_{0.}}{N}\dfrac{N_{.0}}{N}}\right)\\
&=\frac{N_{11}}{N}\log_2\left(\frac{NN_{11}}{N_{1.}N_{.1}}\right)+\frac{N_{01}}{N}\log_2\left(\frac{NN_{01}}{N_{0.}N_{.1}}\right)\\
&+\frac{N_{10}}{N}\log_2\left(\frac{NN_{10}}{N_{1.}N_{.0}}\right)+\frac{N_{00}}{N}\log_2\left(\frac{NN_{00}}{N_{0.}N_{.0}}\right)\\
&=\frac{49}{801,948}\log_2\left(\frac{801,948\cdot 49}{(49+27,652)(49+141)}\right)\\
&+\frac{141}{801,948}\log_2\left(\frac{801,948\cdot 141}{(141+774,106)(49+141)}\right)\\
&+\frac{27,652}{801,948}\log_2\left(\frac{801,948\cdot 27,652}{(49+27,652)(27,652+774,106)}\right)\\
&+\frac{774,106}{801,948}\log_2\left(\frac{801,948\cdot 774,106}{(141+774,106)(27,652+774,106)}\right)\cong 0.000105
\end{aligned}\tag{9.5.27}$$

For two variables it is possible to represent the different entropic quantities with an analogy to set theory. In the figure below we see the different quantities, and how the mutual information is the to x and y:

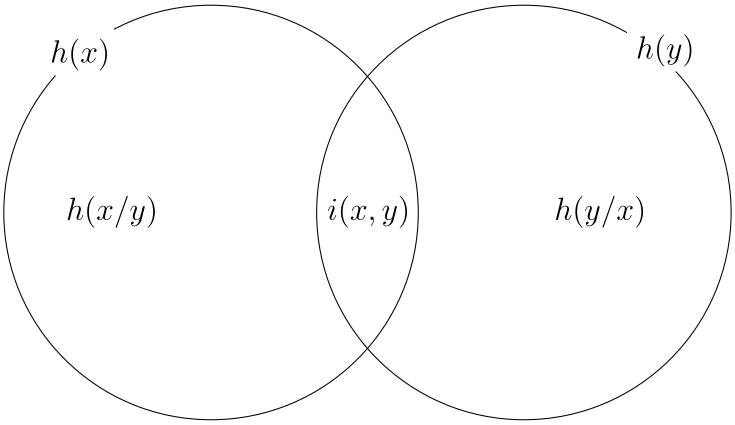

Figure 9.134: **Graphical representation of the conditional entropy and the mutual information**

From which, and using the previous results, we deduce, taking $\lambda = p(x,y)$, that:

$$\begin{aligned}I(x,y) &= \lambda \sum_{x,y} P(x,y)\log\left(\frac{P(x,y)}{P(x)P(y)}\right)\\ &= h(x)-h(x/y)\\ &= h(y)-h(y/x)\\ &= \underbrace{h(x)+h(y)}_{\text{max entropy}} - \underbrace{h(x,y)}_{\text{joint entropy}}\end{aligned} \tag{9.5.28}$$

If x and y are independent (x tell us nothing about y), then $h(y/x)=h(y)$ and therefore we have for the mutual information (the two sets are completely separated):

$$\text{MMI} = I(x,y) = h(y)-h(y/x) = h(y)-h(y) = 0 \tag{9.5.29}$$

or equivalently:

$$\text{MMI} = I(x,y) = h(x)+h(y)-h(x,y) = h(x)+h(y)-(h(x)+h(y)) = 0 \tag{9.5.30}$$

If x tell us everything you y then $h(y/x)=0$ and we have (both sets are completely superposed):

$$\text{MMI} = I(x,y) = h(y)-h(y/x) = h(y) \tag{9.5.31}$$

Remark

Some methods in advanced statistics and therefore data science use the MMI rather than the Pearson correlation coefficient as we know that this latter has some issues for special cases of non-linear regressions (see section Statistics page 615). However the difficulty in practice is that it requires to know the joint probability distribution function for the variables and some form of discretization using kernels.

✍**Examples:**

E1. Given a binary random variable which value is 1 with probability p (and therefore 0 with probability $1-p$). Its entropy is given by:

$$\begin{gathered}S_2(p)=S_2(1-p)\Leftrightarrow S_2(p)-S_2(1-p)=0\\ \Rightarrow -p\lambda\log(p)-(1-p)\lambda\log(1-p)=0\end{gathered} \tag{9.5.32}$$

with obviously $0<p<1$ and with a logarithm in base 2 such that for any event with two equiprobable states, the entropy of obtaining one of the two states is equal to unity. Indeed:

$$S_2(p)=-p\lambda\log_2(p)=-0.5\lambda\log_2(0.5)=-0.5\lambda\cdot -1=1 \tag{9.5.33}$$

Therefore we must have $\lambda=1$.

The entropy is shown in the figure below, in "Shannon" units (unit corresponding to the use of the logarithm with base 2). We remark its symmetry about the value $1/2$ value at which it reaches its maximum, equal to 1 as expected intuitively for such an experience.

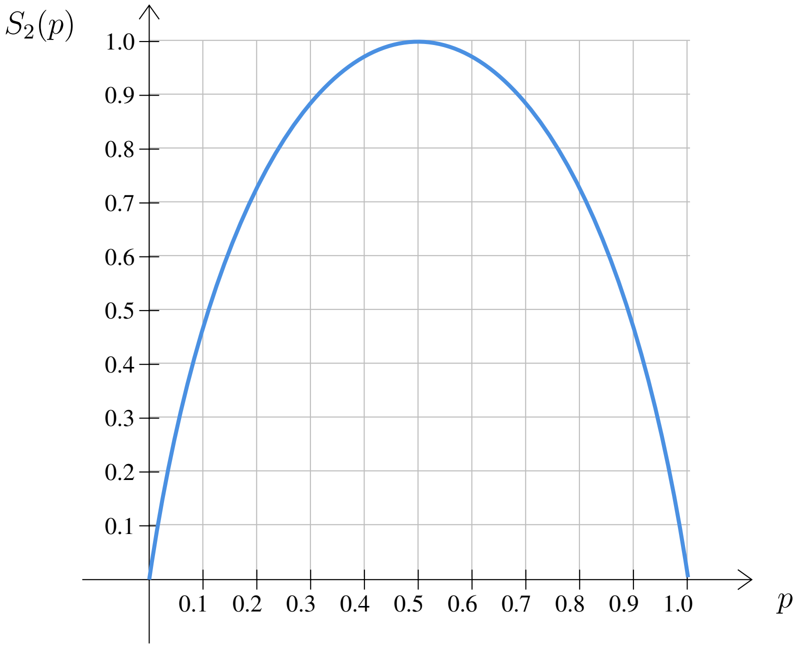

Figure 9.135: **Entropy of a binary variable with $\lambda=1$**

E2. In the field of astronomy where it is often necessary to compress images we seek to calculate the "data redundancy level" to choose a compression ratio eventually applicable. This is done by calculating the information contained in an image using its entropy. Given an image whose pixels are coded on N bits, thus 2^N possible values by pixels, and a proportion (probability) p_i of pixels that can take each color. The entropy of the image is given by (with the notation usage that is traditional in digital imaging):

$$H=-\sum_{i=1}^{2^N} p_i\log_2(p_i) \tag{9.5.34}$$

which is therefore expressed in bits per pixel and represents the number of bits that are necessary to encode the image without loss of information.

E3. We have seen during our study of combinatorics that to give the strength of a password based on the number of combination was not very a convenient way to communicate. That's why most IT professional like to give the entropy of a password in bits! Let us for example consider a password of 8 characters from an alphabet of 94 characters (all characters that can be made with a standard keyboard user). Then we have using the tradition of IT professionals :

$$H=-\lambda\sum_{i=1}^{2^N} p_i\log_2(p_i)=\log_2(94^8)\cong\log_2(2^{52})=52 \tag{9.5.35}$$

Hence according to this empirical tradition such a password has an entropy of 52 bits and such a number is indeed much more convenient to communicate than the huge value of the combinatorics!

The entropy of a discrete random variable is a non-negative number:

$$H(X)=-\sum_{x\in\mathcal{X}} p(x)\cdot\log_b p(x)\geq 0 \tag{9.5.36}$$

The minus sign can be moved into the sum:

$$H(X)=\sum_{x\in\mathcal{X}}[p(x)\cdot(-\log_b p(x))] \tag{9.5.37}$$

Because the co-domain of probability mass functions is $[0,1]$, we can deduce:

$$\begin{array}{rcccl} 0 & \leq & p(x) & \leq & 1\\ -\infty & \leq & \log_b\left(p(x)\right) & \leq & 0\\ 0 & \leq & -\log_b\left(p(x)\right) & \leq & +\infty\\ 0 & \leq & p(x)\cdot\left[-\log_b\left(p(x)\right)\right] & \leq & +\infty \end{array}$$

By convention, $0\cdot\log_b(0)$ is taken to be 0 when calculating entropy, consistent with:

$$\lim_{p\rightarrow 0}[p\log_b(p)]=0 \tag{9.5.38}$$

Taking this together, each term in the sum is positive or zero and thus, the entire sum must also be non-negative.

Remark

Computer scientists use "algorithmic entropy as a special case of entropy as studied in Statistical Mechanics. This viewpoint allows them to apply many techniques developed for use in thermodynamics to the subject of algorithmic information theory. They take the log runtime, length, and output of a program as observables analogous to the energy E, volume V and number of molecules N in a container of gas. The conjugate variables of these observables allow them to define quantities which they name the "algorithmic temperature" T, "algorithmic pressure", P and "algorithmic potential" μ, since they are analogous to the temperature, pressure and chemical potential.

Later we will make the connection between the Statistical Information Theory and Statistical Mechanics!

9.5.1.1 High Entropy Structures

Now we want to understand why there are alloys (or other similar structures) named "high entropy alloys" (HEA) like the $\mathrm{AlCoCrFeNi}$ with body-centered cubic (BCC) lattice and illustrated as:

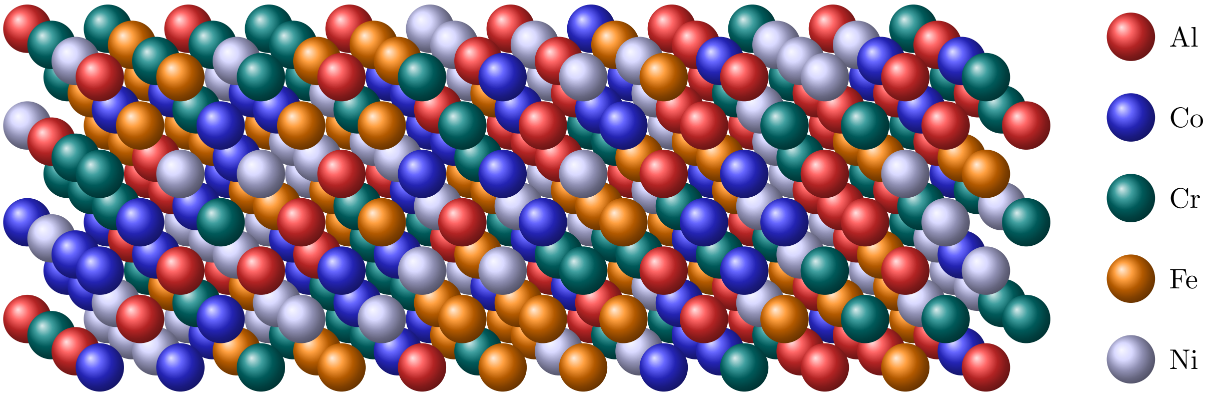

Figure 9.136: $\mathrm{AlCoCrFeNi}$ **High Entropy Alloy (author: Janosh Riebesell)**

To understand let's say we have 3 buckets with 4 balls each. The balls have the following colors:

- Bucket 1: 4 red balls
- Bucket 2: 3 red balls and 1 blue ball
- Bucket 3: 2 red balls and 2 blue balls

And we will judge these three options by how much information we have on the color of a ball drawn at random. In this case, we have the following:

1. In the first bucket, we will know for sure that the ball coming out is red.

2. In the second bucket, we know with 75% certainty that the ball is red, and with 25% certainty that it is blue.
3. In the third bucket, we know with 50% certainty that the ball is red, and with the same certainty that it is blue.

So it makes sense to say that Bucket 1 gives us the most amount of "knowledge" about what ball we will draw (because we know for sure it is red), that Bucket 2 gives us some knowledge, and that Bucket 3 will give us the least amount of knowledge. Well, Entropy is in some way, the opposite of knowledge. So we will say that Bucket 1 has the least amount of entropy, Bucket 2 has medium entropy, and Bucket 3 has the greatest amount of entropy.

How de we compute the entropy for this game? For sure, we will use probabilities!

So now the question is, how do we cook up a formula which gives us a low number for a bucket with 4 red balls, a high number for a bucket with 2 red and 2 blue balls, and a medium number for a bucket with 3 red and 1 blue balls? Well, as a first attempt, let us remember the definition of entropy: If molecules have many possible rearrangements, then the system has high entropy, and if they have very few rearrangements, then the system has low entropy. So a first attempt would be to count the number of rearrangements of these balls. In this case, we have 1 possible rearrangement for Bucket 1, 4 for Bucket 2, and 6 for Bucket 3, this number given by the binomial coefficient.

This number of arrangements won't be part of the formula for entropy, but it gives us an idea, that if there are many arrangements, then entropy is large, and if there are very few arrangements, then entropy is low. In the next section, we will cook up a formula for entropy. The idea is, to consider the probability of drawing the balls in a certain way, from each bucket (each time we draw a ball we put it back in the bucket!!!!).

Consider the following cases:

- The Bucket 1 has 4 red balls (`RRRR`). Then the probability of drawing the balls in the same order (as there are all red and hence indistinguishable) is:

$$1 \cdot 1 \cdot 1 \cdot 1 = 1$$

- The Bucket 2 has 3 red balls and 1 green ball (`RRRG`). Then the probability of drawing the balls in the same order is (don't forget that each time we draw a ball we put it back in the bucket!!!!):

$$0.75 \cdot 0.75 \cdot 0.75 \cdot 0.25 = 0.105$$

- The Bucket 3 has 2 red balls and 2 green ball2 (`RRGG`). Then the probability of drawing the balls in the same order is (don't forget that each time we draw a ball we put it back in the bucket!!!!):

$$0.5 \cdot 0.5 \cdot 0.5 \cdot 0.5 = 0.0625$$

Ok, now we have some measure that gives us different values for the three Buckets. In order to build the entropy formula, we want the opposite, some measure that gives us a low number for

Bucket 1, a medium number for Bucket 2, and a high number for Bucket 3. No problem, this is where the entropy relation will be useful:

$$S(X)=\mathrm{E}(h(x))=-\lambda\sum_{i=1}^{n}P_i\log\left(P_i\right)$$

Taking the logarithm for example in base 10 and $\lambda=1$, we get:

- The Bucket 1:
$$S(X)=\mathrm{E}(h(x))=-\sum_{i=1}^{n}P_i\log\left(P_i\right)=0$$
- The Bucket 2:
$$S(X)=\mathrm{E}(h(x))=-\sum_{i=1}^{n}P_i\log\left(P_i\right)\cong 0.431$$
- The Bucket 3:
$$S(X)=\mathrm{E}(h(x))=-\sum_{i=1}^{n}P_i\log\left(P_i\right)\cong 0.602$$

So indeed the great the mixtures of balls, the higher is the entropy. Hence the name of hight entropy alloys.

9.5.1.2 Usual Shannon entropies

Let us see some common Shannon entropies:

1. For a random variable following a discrete uniform distribution:

   Let X be a random variable following a discrete uniform distribution:
   $$X\sim\mathcal{U}(a,b) \tag{9.5.39}$$
   Then, the (Shannon) entropy of X in nats is:
   $$H(X)=\ln(b-a+1) \tag{9.5.40}$$
   Indeed, the entropy is defined as the probability-weighted average of the logarithmized probabilities for all possible values:
   $$H(X)=-\sum_{x\in\mathcal{X}}p(x)\cdot\log_b\left(p(x)\right) \tag{9.5.41}$$

Entropy is measured in nats by setting $b=e$. Then, with the probability mass function of the discrete uniform distribution (see section Statistics page 649), we have:

$$\begin{aligned}H(X)&=-\sum_{x\in\mathcal{X}}p(x)\cdot\log_e p(x)=-\sum_{x=a}^{b}p(x)\cdot\ln\left(p(x)\right)\\&=-\sum_{x=a}^{b}\frac{1}{b-a+1}\cdot\ln\left(\frac{1}{b-a+1}\right)\\&=-(b-a+1)\cdot\frac{1}{b-a+1}\cdot\ln\left(\frac{1}{b-a+1}\right)\\&=-\ln\left(\frac{1}{b-a+1}\right)=\ln(b-a+1)\end{aligned}\tag{9.5.42}$$

The reasoning is exactly similar for the continuous uniform distribution (see section Statistics page 738) and leads to the result: $H(X)=\ln(b-a)$.

2. For a random variable following a Bernoulli distribution:

   Now let X be a random variable following a Bernoulli distribution:

   $$X\sim\text{Bern}(p)\tag{9.5.43}$$

   Then, the (Shannon) entropy of X in bits is:

   $$H(X)=-p\log_2(p)-(1-p)\log_2(1-p)\tag{9.5.44}$$

   Indeed, the Shannon entropy is defined as the probability-weighted average of the logarithmized probabilities for all possible values:

   $$H(X)=-\sum_{x\in\mathcal{X}}p(x)\cdot\log_b\left(p(x)\right)\tag{9.5.45}$$

   Entropy is measured in bits by setting $b=2$. Since there are only two possible outcomes for a Bernoulli random variable, we have:

   $$\begin{aligned}H(X)&=-P(X=0)\cdot\log_2\left(P(X=0)\right)-P(X=1)\cdot\log_2\left(P(X=1)\right)\\&=-p\log_2(p)-(1-p)\log_2(1-p)\end{aligned}\tag{9.5.46}$$

3. For a random variable following a Normal distribution:

   Now let X be a random variable following a Normal distribution:

   $$X\sim\mathcal{N}\left(\mu,\sigma^2\right)\tag{9.5.47}$$

   Then, the differential entropy of X is:

   $$h(X)=\frac{1}{2}\ln\left(2\pi\sigma^2 e\right)\tag{9.5.48}$$

   Indeed, remember that the differential entropy of a random variable is defined as:

   $$h(X)=-\int_{\mathcal{X}}p(x)\log_b(p(x))\mathrm{d}x\tag{9.5.49}$$

To measure $h(X)$ in nats, we set $b=e$, such that:

$$h(X)=-\mathrm{E}[\ln(p(x))] \tag{9.5.50}$$

With the probability density function of the Normal distribution (see section Statistics page 692), the differential entropy of X is:

$$\begin{aligned}h(X)&=-\mathrm{E}\left[\ln\left(\frac{1}{\sqrt{2\pi}\sigma}\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\right)\right]\\&=-\mathrm{E}\left[-\frac{1}{2}\ln\left(2\pi\sigma^2\right)-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\\&=\frac{1}{2}\ln\left(2\pi\sigma^2\right)+\frac{1}{2}\mathrm{E}\left[\left(\frac{x-\mu}{\sigma}\right)^2\right]\\&=\frac{1}{2}\ln\left(2\pi\sigma^2\right)+\frac{1}{2}\cdot\frac{1}{\sigma^2}\cdot\mathrm{E}\left[(x-\mu)^2\right]\end{aligned} \tag{9.5.51}$$

Note that $\mathrm{E}\left[(x-\mu)^2\right]$ corresponds to the variance of X and the variance of the normal distribution is σ^2. Thus, we can proceed:

$$\begin{aligned}h(X)&=\frac{1}{2}\ln\left(2\pi\sigma^2\right)+\frac{1}{2}\cdot\frac{1}{\sigma^2}\cdot\sigma^2\\&=\frac{1}{2}\ln\left(2\pi\sigma^2\right)+\frac{1}{2}\\&=\frac{1}{2}\ln\left(2\pi\sigma^2 e\right)\end{aligned} \tag{9.5.52}$$

4. For a random variable following a multivariate Normal distribution:

   Let x follow a multivariate normal distribution:

   $$x\sim\mathcal{N}(\mu,\Sigma) \tag{9.5.53}$$

   Then, the differential entropy of x in nats is:

   $$h(x)=\frac{n}{2}\ln(2\pi)+\frac{1}{2}\ln|\Sigma|+\frac{1}{2}n \tag{9.5.54}$$

   Indeed, the differential entropy of a random variable is defined as:

   $$h(X)=-\int_{\mathcal{X}}p(x)\log_b(p(x))\mathrm{d}x \tag{9.5.55}$$

   To measure $h(X)$ in nats, we set $b=e$, such that:

   $$h(X)=-\mathrm{E}[\ln(p(x))] \tag{9.5.56}$$

   With the probability density function of the multivariate normal distribution , the differential entropy of x is:

   $$\begin{aligned}h(x)&=-\mathrm{E}\left[\ln\left(\frac{1}{\sqrt{(2\pi)^n|\Sigma|}}\cdot\exp\left[-\frac{1}{2}(x-\mu)^T\Sigma^{-1}(x-\mu)\right]\right)\right]\\&=-\mathrm{E}\left[-\frac{n}{2}\ln(2\pi)-\frac{1}{2}\ln|\Sigma|-\frac{1}{2}(x-\mu)^T\Sigma^{-1}(x-\mu)\right]\\&=\frac{n}{2}\ln(2\pi)+\frac{1}{2}\ln|\Sigma|+\frac{1}{2}\mathrm{E}\left[(x-\mu)^T\Sigma^{-1}(x-\mu)\right]\end{aligned} \tag{9.5.57}$$

The last term can be evaluated as:

$$\begin{aligned}\mathrm{E}\left[(x-\mu)^T\Sigma^{-1}(x-\mu)\right]&=\mathrm{E}\left[\mathrm{tr}\left((x-\mu)^T\Sigma^{-1}(x-\mu)\right)\right]\\&=\mathrm{E}\left[\mathrm{tr}\left(\Sigma^{-1}(x-\mu)(x-\mu)^{\mathrm{T}}\right)\right]\\&=\mathrm{tr}\left(\Sigma^{-1}\mathrm{E}\left[(x-\mu)(x-\mu)^T\right]\right)\\&=\mathrm{tr}\left(\Sigma^{-1}\Sigma\right)=\mathrm{tr}\left(I_n\right)=n\end{aligned} \tag{9.5.58}$$

such that the differential entropy is:

$$h(x)=\frac{n}{2}\ln(2\pi)+\frac{1}{2}\ln|\Sigma|+\frac{1}{2}n \tag{9.5.59}$$

9.5.1.3 Perplexity

"Perplexity" is a concept used in Text Mining and some Machine Learning algorithms (we will see much later a usage of that latter during our study of the T-SNE at page 6939) and defined as:

$$\boxed{\mathrm{Perp}(p)=b^{S(p)}=b^{\mathrm{E}[\log_b(p)]}} \tag{9.5.60}$$

where b is the base of the logarithm used. We can already point out that perplexity is invariant with the base we use to define entropy. So in this sense, perplexity is infinitely more unique/less arbitrary than entropy as a measurement.

For discrete case, suppose we have n discrete states:

$$\mathrm{Perp}(p)=b^{S(p)}=b^{-\sum_{i=1}^n p(x_i)\log_b p(x_i)} \tag{9.5.61}$$

So it has the exact same information to Shannon entropy. And we will explain now why people invented this!

A very common version of the above relation is in base $b=2$. We then have:

$$\mathrm{Perp}(2)=2^{S(p)}=2^{-\sum_{i=1}^n p(x_i)\log_2 p(x_i)} \tag{9.5.62}$$

Now to understand the origin consider N events equally likely. We then have using the definition and properties of exponentiation and logarithm we get:

$$\mathrm{Perp}(2)=2^{S(p)}=2^{-\sum_{i=1}^n \frac{1}{N}\log_2 p(x_i)}=\left(\prod_{i=1}^n\frac{1}{p(x_i)}\right)^{\frac{1}{N}}=\sqrt{\prod_{i=1}^n\frac{1}{p(x_i)}} \tag{9.5.63}$$

So the perplexity can be seen as the geometric average of the inverse probabilities!

Let's play with this a bit. Let's say you're just looking at a coin. When the coin is fair, entropy is at a maximum, and perplexity is at a maximum of:

$$\frac{1}{\frac{1}{2}^{\frac{1}{2}}\cdot\frac{1}{2}^{\frac{1}{2}}}=2 \tag{9.5.64}$$

Now what happens when we look at an N sided dice? Perplexity is:

$$\frac{1}{\left(\frac{1}{N}^{\frac{1}{N}}\right)^{N}}=N \tag{9.5.65}$$

So perplexity represents the number of sides of a fair die that when rolled, produces a sequence with the same entropy as your given probability distribution.

Therefore perplexity of whatever you're evaluating, on the data we are evaluating it on, sort of tells « *us this thing is right about as often as a x-sided die would be*».

9.5.1.4 Kullback–Leibler divergence

In mathematical statistics, the Kullback–Leibler divergence (also called "relative entropy") is a measure of how one probability distribution diverges from a second, expected probability distribution. Applications include characterizing the relative (Shannon) entropy in information systems, randomness in continuous time-series, and information gain when comparing statistical models of inference. In contrast to variation of information, it is a distribution-wise asymmetric measure and thus does not qualify as a statistical metric of spread. In the simple case, a Kullback–Leibler divergence of 0 indicates that we can expect similar, if not the same, behaviour of two different distributions, while a Kullback–Leibler divergence of 1 indicates that the two distributions behave in such a different manner that the expectation given the first distribution approaches zero. In simplified terms, it is a measure of surprise, with diverse applications such as in statistics and Machine Learning (see section Numerical Methods page 6768).

Given the Shannon entropy introduced earlier before:

$$S(X)=-\lambda\sum_{i=1}^{n}p_i(x)\log(p_i(x)) \tag{9.5.66}$$

Kullback-Leibler Divergence is just a slight modification of our formula for entropy. Rather than just having our probability distribution p_X we add in an approximating distribution p_Y. Then we look at the difference of the log values for each (and we put $\lambda=1$):

$$D_{\text{KL}}(p_X,p_Y)=\sum_{i=1}^{n}p_X(x_i)\left(\log(p_X(x_i)-p_Y(x_i)\right) \tag{9.5.67}$$

Essentially, what we're looking at with the KL divergence is the expectation of the log difference between the probability of data in the original distribution with the approximating distribution. So the Kullback–Leibler divergence is measure of entropy increase due to the use of an approximation to the true distribution rather than the true distribution itself.

The "discrete Kullback-Leibler divergence" between two distributions X and Y is given by:

$$\boxed{D_{\text{KL}}(p_X,p_Y)=\sum_{x\in S}p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)} \tag{9.5.68}$$

also sometimes denoted:

$$\mathrm{KL}(p_X||p_Y)=\sum_{x\in S}p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)\tag{9.5.69}$$

and the "continuous Kullback-Leibler divergence" between two distributions X and Y is given by:

$$\boxed{D_{\mathrm{KL}}(p_X,p_Y)=\int p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)\mathrm{d}x}\tag{9.5.70}$$

The Kullback-Leibler divergence is a kind of distance between the probability distributions of X and Y, although $D_{\mathrm{KL}}(p_X,p_Y)\neq D_{\mathrm{KL}}(p_Y,p_X)$ (but it is therefore not a true "distance" because it is asymmetric!!!!).

As it is quite abstract let us do a companion example of two Normal distributions:

$$p_X=\mathcal{N}(\mu,\sigma^2)\qquad p_Y=\mathcal{N}(m,s^2)\tag{9.5.71}$$

So now we want obviously to calculate:

$$\begin{aligned}D_{\mathrm{KL}}(p_X,p_Y)&=\int p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)\mathrm{d}x=\int p_X(x)\log\left(\frac{\dfrac{1}{\sqrt{2\pi\sigma^2}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}}{\dfrac{1}{\sqrt{2\pi s^2}}e^{-\frac{(x-m)^2}{2s^2}}}\right)\mathrm{d}x\\&=\int p_X(x)\log\left(\sqrt{\frac{s^2}{\sigma^2}}\right)\mathrm{d}x+\int p_X(x)\log\left(-\frac{(x-\mu)^2}{2\sigma^2}+\frac{(x-m)^2}{2s^2}\right)\mathrm{d}x\\&=\frac{1}{2}\log\left(\frac{s^2}{\sigma^2}\right)\int p_X(x)\mathrm{d}x+\frac{1}{2\sigma^2}\left[-\int(x-\mu)^2p_X(x)\mathrm{d}x\right]+\frac{1}{2s^2}\left[\int(x-m)^2p_X(x)\mathrm{d}x\right]\end{aligned}\tag{9.5.72}$$

But we have:

$$\int p_X(x)\mathrm{d}x=1\tag{9.5.73}$$

and:

$$\int(x-\mu)^2p_X(x)\mathrm{d}x=\int x^2p_X(x)\mathrm{d}x-\int 2\mu x\mathrm{d}x+\int\mu^2p_X(x)\mathrm{d}x=\sigma^2-2\mu^2+\mu^2=\sigma^2\tag{9.5.74}$$

Therefore:

$$D_{\mathrm{KL}}(p_X,p_Y)=\frac{1}{2}\log\left(\frac{s^2}{\sigma^2}\right)-\frac{\sigma^2}{2\sigma^2}+\frac{1}{2s^2}\left[\int(x-m)^2p_X(x)\mathrm{d}x\right]\tag{9.5.75}$$

But we have:

$$\begin{aligned}\int(x-m)^2p_X(x)\mathrm{d}x&=\int(x-\mu+\mu-m)^2p_X(x)\mathrm{d}x\\&=\int(x-\mu)^2p_X(x)\mathrm{d}x+(\mu-m)^2\int p_X(x)\mathrm{d}x+2(\mu-m)\int(x-\mu)p_X(x)\mathrm{d}x\\&=\sigma^2+(\mu-m)^2+2(\mu-m)\left[\int xp_X(x)\mathrm{d}x-\mu\int p_X(x)\mathrm{d}x\right]\\&=\sigma^2+(\mu-m)^2+2(\mu-m)(\mu-\mu)=\sigma^2+(\mu-m)^2\end{aligned}\tag{9.5.76}$$

Therefore:

$$\begin{aligned}D_{\text{KL}}(p_X,p_Y)=\frac{1}{2}\log\left(\frac{s^2}{\sigma^2}\right)-\frac{1}{2}+\frac{1}{2s^2}\left[\int(x-m)^2p_X(x)\mathrm{d}x\right]&=\frac{1}{2}\log\left(\frac{s^2}{\sigma^2}\right)-\frac{1}{2s^2}\left[\sigma^2+(\mu-m)^2\right]\\&=\frac{1}{2}\left[\log\left(\frac{s^2}{\sigma^2}\right)-1+\frac{\sigma^2+(\mu-m)^2}{s^2}\right]\end{aligned} \tag{9.5.77}$$

So finally:

$$D_{\text{KL}}\left(\mathcal{N}(\mu,\sigma),\mathcal{N}(m,s)\right)=\frac{1}{2}\left[\log\left(\frac{s^2}{\sigma^2}\right)-1+\frac{\sigma^2+(\mu-m)^2}{s^2}\right] \tag{9.5.78}$$

Let us take another example based on two discrete uniform distribution $p=\mathcal{U}(a_1,b_1)$ and $q=\mathcal{U}(a_2,b_2)$ and as we know the cumulative distribution function of the latter (see section Statistics page 649), then we have:

$$\begin{aligned}D_{\text{KL}}(p_X,p_Y)&=\sum_{x=a_1}^{b_1}\frac{1}{b_1-a_1+1}\cdot\ln\left(\frac{\frac{1}{b_1-a_1+1}}{\frac{1}{b_2-a_2+1}}\right)\\&=\frac{1}{b_1-a_1+1}\cdot\ln\left(\frac{b_2-a_2+1}{b_1-a_1+1}\right)\sum_{x=a_1}^{b_1}1\\&=\frac{1}{b_1-a_1+1}\cdot\ln\left(\frac{b_2-a_2+1}{b_1-a_1+1}\right)\cdot(b_1-a_1+1)\\&=\ln\left(\frac{b_2-a_2+1}{b_1-a_1+1}\right)\end{aligned} \tag{9.5.79}$$

The reasoning is exactly similar for the continuous uniform distribution (see section Statistics page 738) and leads to the result:

$$D_{\text{KL}}(p_X,p_Y)=\ln\left(\frac{b_2-a_2}{b_1-a_1}\right) \tag{9.5.80}$$

Taking another example based on the Bernoulli distributions:

$$P(X=x)=\begin{cases}p & \text{if } x=1\\1-p & \text{if } x=0\\0 & \text{otherwise}\end{cases}\qquad P(X=x)=\begin{cases}q & \text{if } x=1\\1-q & \text{if } x=0\\0 & \text{otherwise}\end{cases} \tag{9.5.81}$$

we have straightforward:

$$D_{\text{KL}}(p_X,p_Y)=p\log\left(\frac{p}{q}\right)+(1-p)\log\left(\frac{1-p}{1-q}\right) \tag{9.5.82}$$

The Kullback–Leibler divergence has the following properties:

P1. It is positive definite such that $D_{\text{KL}}\geq 0$

Proof 9.10.2. We start from:

$$D_{\mathrm{KL}}(p_X,p_Y)=\sum_{x\in S}p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)=-\sum_{x\in S}p_X(x)\log\left(\frac{p_Y(x)}{p_X(x)}\right) \tag{9.5.83}$$

As $-\log(z)$ is a convex function we can apply the Jensen's equality (see section Statistics page 576) that is given for recall by:

$$f(\mathrm{E}(X))\leq \mathrm{E}(f(X)) \tag{9.5.84}$$

Therefore:

$$-\log\left(\sum_{x\in S}p_X(x)\frac{p_Y(x)}{p_X(x)}\right)\leq -\sum_{x\in S}p_X(x)\log\left(\frac{p_Y(x)}{p_X(x)}\right) \tag{9.5.85}$$

Hence if we simplify:

$$-\log\left(\sum_{x\in S}p_Y(x)\right)\leq -\sum_{x\in S}p_X(x)\log\left(\frac{p_Y(x)}{p_X(x)}\right) \tag{9.5.86}$$

This is equal to write:

$$-\log(1)\leq -\sum_{x\in S}p_X(x)\log\left(\frac{p_Y(x)}{p_X(x)}\right) \tag{9.5.87}$$

Hence:

$$0\leq -\sum_{x\in S}p_X(x)\log\left(\frac{p_Y(x)}{p_X(x)}\right) \tag{9.5.88}$$

Therefore:

$$\sum_{x\in S}p_X(x)\log\left(\frac{p_X(x)}{p_Y(x)}\right)\geq 0 \tag{9.5.89}$$

■ Q.E.D.

P2. It is zero if both distribution are equal $D_{\mathrm{KL}}(p_X,p_Y)=0$ if $p_X=p_Y$.

Proof 9.10.3. The proof is immediate:

$$D_{\mathrm{KL}}(p_X,p_x)=\sum_{x\in S}p_X(x)\log\left(\frac{p_X(x)}{p_X(x)}\right)=\sum_{x\in S}p_X(x)\log(1)=\sum_{x\in S}p_X(x)\cdot 0=0 \tag{9.5.90}$$

■ Q.E.D.

Thanks to the first property we can prove that the discrete uniform distribution maximizes (Shannon) entropy for a random variable with finite support. Let us remind first that the Shannon entropy is defined by:

$$H(X)=-\sum_{x\in\mathcal{X}}p(x)\log(p(x)) \tag{9.5.91}$$

And that we have for the Kullback-Leibler divergence:

$$\begin{aligned}0\leq D_{\text{KL}}(f,g)&=\sum_{x\in\mathcal{X}}f(x)\log\left(\frac{f(x)}{g(x)}\right)\\&=\sum_{x\in\mathcal{X}}f(x)\log\left(f(x)\right)-\sum_{x\in\mathcal{X}}f(x)\log\left(g(x)\right)\\&=-H[f(x)]-\sum_{x\in\mathcal{X}}f(x)\log\left(g(x)\right)\end{aligned}\tag{9.5.92}$$

By plugging the probability mass function of the discrete uniform distribution (see section Statistics page 649) into the second term, we get:

$$\sum_{x\in\mathcal{X}}f(x)\log\left(g(x)\right)=\sum_{x=1}^{n}f(x)\log\left(\frac{1}{n-1+1}\right)=\log\left(\frac{1}{n}\right)\sum_{x=1}^{n}f(x)=-\log(n)\tag{9.5.93}$$

This is actually the negative of the Shannon entropy of the discrete uniform distribution (proven earlier above) such that:

$$\sum_{x\in\mathcal{X}}f(x)\log g(x)=-H\left(\mathcal{U}(1,n)\right)=-\text{H}[g(x)]\tag{9.5.94}$$

Combining the previous results above with the previous one, we get:

$$\begin{aligned}0&\leq D_{\text{KL}}(f,g)\\0&\leq -H(f(x))-(-H(g(x)))\\H(g(x))&\geq H(f(x))\end{aligned}\tag{9.5.95}$$

which means that the entropy of the discrete uniform distribution $\mathcal{U}(a,b)$ will be larger than or equal to any other distribution defined on the same set of values $\{a,\ldots,b\}$! Obviously the same reasoning and conclusion applies for the continuous uniform distribution.

Let X be a random variable. Assume two Bernoulli distributions P and Q specifying the probability distribution of X as:

$$\begin{aligned}P&:X\sim\text{Bern}\left(p_1\right)\\Q&:X\sim\text{Bern}\left(p_2\right)\end{aligned}\tag{9.5.96}$$

Then, the Kullback-Leibler divergence of P from Q is given by:

$$D_{\text{KL}}(p,q)=\ln\left(\frac{1-p_1}{1-p_2}\right)+p_1\cdot\ln\left(\frac{p_1\left(1-p_2\right)}{p_2\left(1-p_1\right)}\right)\tag{9.5.97}$$

Indeed, remember that for a discrete random variable the Kullback-Leibler divergence is given by:

$$D_{\text{KL}}(p,q)=\sum_{x\in\mathcal{X}}p(x)\ln\left(\frac{p(x)}{q(x)}\right)\tag{9.5.98}$$

which, applied to the Bernoulli distributions in, yields:

$$\begin{aligned}D_{\text{KL}}(p,q)&=\sum_{x\in\{0,1\}}p(x)\ln\left(\frac{p(x)}{q(x)}\right)\\&=p(X=0)\cdot\ln\left(\frac{p(X=0)}{q(X=0)}\right)+p(X=1)\cdot\ln\left(\frac{p(X=1)}{q(X=1)}\right)\end{aligned}\tag{9.5.99}$$

Using the probability mass function of the Bernoulli distribution (see section Probabilities page 652), this becomes:

$$\begin{aligned}D_{\text{KL}}(p,q)&=(1-p_1)\cdot\ln\left(\frac{1-p_1}{1-p_2}\right)+p_1\cdot\ln\left(\frac{p_1}{p_2}\right)\\&=\ln\left(\frac{1-p_1}{1-p_2}\right)+p_1\cdot\ln\left(\frac{p_1}{p_2}\right)-p_1\cdot\ln\left(\frac{1-p_1}{1-p_2}\right)\\&=\ln\left(\frac{1-p_1}{1-p_2}\right)+p_1\cdot\left[\ln\left(\frac{p_1}{p_2}\right)+\ln\left(\frac{1-p_2}{1-p_1}\right)\right]\\&=\ln\left(\frac{1-p_1}{1-p_2}\right)+p_1\cdot\ln\left(\frac{p_1\left(1-p_2\right)}{p_2\left(1-p_1\right)}\right)\end{aligned}\tag{9.5.100}$$

Now let X be a random variable. Assume two binomial distributions P and Q specifying the probability distribution of X as:

$$\begin{aligned}P&:X\sim\text{Bin}\left(n,p_1\right)\\Q&:X\sim\text{Bin}\left(n,p_2\right)\end{aligned}\tag{9.5.101}$$

Then, the Kullback-Leibler divergence of P from Q is given by:

$$D_{\text{KL}}(p,q)=np_1\cdot\ln\left(\frac{p_1}{p_2}\right)+n\left(1-p_1\right)\cdot\ln\left(\frac{1-p_1}{1-p_2}\right)\tag{9.5.102}$$

Indeed, as the Kullback-Leibler divergence for a discrete random variable is given by:

$$D_{\text{KL}}(p,q)=\sum_{x\in\mathcal{X}}p(x)\ln\left(\frac{p(x)}{q(x)}\right)\tag{9.5.103}$$

which, applied to the binomial distributions yields:

$$\begin{aligned}D_{\text{KL}}(p,q)&=\sum_{x=0}^{n}p(x)\ln\left(\frac{p(x)}{q(x)}\right)\\&=p(X=0)\cdot\ln\left(\frac{p(X=0)}{q(X=0)}\right)+\ldots+p(X=n)\cdot\ln\left(\frac{p(X=n)}{q(X=n)}\right)\end{aligned}\tag{9.5.104}$$

Using the probability mass function of the binomial distribution (see section Statistics page 658), this becomes:

$$\begin{aligned}D_{\text{KL}}(p,q)&=\sum_{x=0}^{n}\binom{n}{x}p_1^x\left(1-p_1\right)^{n-x}\cdot\ln\left(\frac{\binom{n}{x}p_1^x\left(1-p_1\right)^{n-x}}{\binom{n}{x}p_2^x\left(1-p_2\right)^{n-x}}\right)\\&=\sum_{x=0}^{n}\binom{n}{x}p_1^x\left(1-p_1\right)^{n-x}\cdot\left[x\cdot\ln\left(\frac{p_1}{p_2}\right)+(n-x)\cdot\ln\left(\frac{1-p_1}{1-p_2}\right)\right]\\&=\ln\left(\frac{p_1}{p_2}\right)\cdot\sum_{x=0}^{n}\binom{n}{x}p_1^x\left(1-p_1\right)^{n-x}x+\ln\left(\frac{1-p_1}{1-p_2}\right)\cdot\sum_{x=0}^{n}\binom{n}{x}p_1^x\left(1-p_1\right)^{n-x}(n-x)\end{aligned}\tag{9.5.105}$$

We can now see that some terms in this sum are expected values with respect to binomial distributions:

$$\begin{gathered}\sum_{x=0}^{n}\left(\begin{array}{c}n\\x\end{array}\right)p_1^x\left(1-p_1\right)^{n-x}x=\mathrm{E}(x)_{\mathrm{Bin}(n,p_1)}\\ \sum_{x=0}^{n}\left(\begin{array}{c}n\\x\end{array}\right)p_1^x\left(1-p_1\right)^{n-x}(n-x)=\mathrm{E}(n-x)_{\mathrm{Bin}(n,p_1)}\end{gathered}\tag{9.5.106}$$

Using the expected value of the binomial distribution, these can be simplified to:

$$\begin{aligned}\mathrm{E}(x)_{\mathrm{Bin}(n,p_1)}&=np_1\\ \mathrm{E}(n-x)_{\mathrm{Bin}(n,p_1)}&=n-np_1\end{aligned}\tag{9.5.107}$$

such that the Kullback-Leibler divergence finally becomes:

$$D_{\mathrm{KL}}(p,q)=np_1\cdot\ln\left(\frac{p_1}{p_2}\right)+n\left(1-p_1\right)\cdot\ln\left(\frac{1-p_1}{1-p_2}\right)\tag{9.5.108}$$

Remark

For a practical numerical application, the reader can refer to our R companion book! The reader may have notice that the Kullback-Leibler divergence is not a distance (i.e. a "metric") as obviously $D_{\mathrm{KL}}(p_X,p_Y)=D_{\mathrm{KL}}(p_Y,p_X)$ (i.e. the KL divergence is not symmetric). This is why there is another approach named the "Wasserstein metric" that doesn't measure the divergence but the distance between two probability distributions!

In an approach to statistical inference based on information theory, the true but unknown distribution is compared with information in the sample using a divergence measure between the population distribution and the sample distribution. The divergence measure may also be used to compare two hypothesized distributions. A general type of divergence measure is named the "ϕ-divergence" and for the PDFs p and q of random variables with a common support D is defined as:

$$\boxed{\int_D\phi\left(\frac{p(y)}{q(y)}\right)\mathrm{d}y}\tag{9.5.109}$$

if the integral exists. The ϕ-divergence is also called the f-divergence. The ϕ-divergence is in general not a metric because it is not symmetric. One function is taken as the base from which the other function is measured. A specific instance of ϕ-divergence that is widely used is the Kullback-Leibler measure introduced just earlier:

$$\int_{\mathbb{R}}p(y)\log\left(\frac{p(y)}{q(y)}\right)\mathrm{d}y\tag{9.5.110}$$

9.5.2 Boltzmann law

First we will demonstrate through a simple case that for any system closed and isolated system, the most likely state is the state is that of equilibrium!

Let us consider an isolated system (a system is said to be "isolated" when it is impervious to any flow - heat (adiabatic), matter, fields, etc.) populated by N distinguishable particles. This system is divided into 2 compartments (or levels) identical and separated by an impermeable wall. Each compartment is assumed to contain a quantity N_1, N_2 number of particles.

For a given configuration of the system, we speak of "microstate" in the sense that it is possible thanks to the quantity of particles to measure a macroscopic known quantity such as energy, mass, pressure, etc.

If we fix this particular system, it is of course possible for number N of particles to imagine a given number of macro-states (don't forget that there are two compartments). Such as:

- One particle: 2 macrostate (2 possible configurations, therefore 1 configuration by macrostate)
- Two particles: 3 macrostate (4 possible configurations by permutations of the compartments
- Three particles: 4 macrostate (8 possible configurations by permutations of the compartments)
- Four particles: 5 macrostate (16 possible configurations by permutations of the compartments)
- n particles: $n+1$ macrostate (2^n possible configurations by permutations of the compartments

Definition (#9.5.456): We name "microstate", a configuration of permutation of macrostate. In the context of the Einstein model of a solid, the term "macrostate" refers to the total amount of energy in the system.

The probability of finding a system in a given state depends upon the multiplicity of that state. That is to say, it is proportional to the number of ways you can produce that state. Here a "state" is defined by some measurable property which would allow you to distinguish it from other states.

✍**Example:**

In throwing a pair of dice, that measurable property is the sum of the number of dots facing up. The multiplicity for two dots showing is just one, because there is only one arrangement of the dice which will give that state. The multiplicity for seven dots showing is six, because there are six arrangements of the dice which will show a total of seven dots:

Total number of microstates: 36
Total number of macrostates: 11

Let us now determine using combinatorial analysis (see section Probabilities page 522) the number of possible microstates for each macro-state named "multiplicity" and denoted by Ω. By analogy, this corresponds to imagine that the system is a stem on which are strung balls (particles) and the stem is separated by an imaginary boundary in one of its points (Chinese abacus). In such a situation, we have:

$$\Omega = \frac{N!}{N_1!N_2!} \tag{9.5.111}$$

This gives us all the possible arrangements of the "lefts particles" with "right particles" (of the border) for a given macro-state (the number of ways in which particles can be shared between the two compartments). But we also have in this particular case:

$$\Omega = \frac{N!}{N_1!N_2!} = \frac{N!}{N_1!(N-N_1)!} = \frac{N!}{(N-N_2)!N_2!} \tag{9.5.112}$$

But this corresponds to the combinatorial such that:

$$C_{N_1}^{N} = \frac{N!}{N_1!(N-N_1)!} \qquad C_{N_2}^{N} = \frac{N!}{(N-N_2)!N_2!} \tag{9.5.113}$$

and therefore:

$$\Omega = \frac{N!}{N_1!N_2} = C_{N_1}^{N} = C_{N_2}^{N} \tag{9.5.114}$$

We finally have for all macrostates of a system of N particles, a total of:

$$\sum_{N_1=0}^{N} C_{N_1}^{N} = \sum_{N_2=0}^{N} C_{N_2}^{N} \tag{9.5.115}$$

possible microstates (configurations). But we have seen in the initial example that:

$$\sum_{N_1=0}^{N} C_{N_1}^{N} = \sum_{N_2=0}^{N} C_{N_2}^{N} = 2^N \tag{9.5.116}$$

Thus, the probability of existence of a given microstate is 2^{-N} and is equally likely!!

We can now state the first postulate of Statistical Mechanics ("Gibbs postulate") all discernible and accessible microstates of an isolated system are equally likely.

Let us go back to our original question about equilibrium:

The notion of equilibrium associated to a macro-state is provided by classical thermodynamics. We say that a system is said to be in equilibrium when its state is characterized by the temporal independence of macroscopic quantities (mass, power, pressure, ...) and the constancy of the thermodynamic potentials (internal energy, enthalpy, Gibbs energy, ...).

To find out why the equilibrium is the most probable state, we only need to find what is the pair (N_1, N_2) that maximizes:

$$\Omega_{\text{max}} := \Omega = \frac{N!}{N_1!N_2!} \tag{9.5.117}$$

since all microstates are equally probable anyway. It is easy to check that this maximum is given for:

$$N_1 = N_2 \tag{9.5.118}$$

We can now announce the second postulate of Statistical Mechanics: the equilibrium state is the state which is the one with the largest number of configurations (microstates) and is the most likely state!!

Or in other words: A system reaches its equilibrium when its entropy is maximum and the entropy can only grow (fundamental postulate in physics!)!!

Remark

Some physicists have supposed that this fundamental postulate of increasing entropy is even stronger that the principle of the Darwin's natural selection model. Indeed, if we imagine molecules dispersed in a primordial ocean, by the principle of entropy, they will self-organize naturally to maximize the dissipation of heat from the ocean. What is powerful is that principle provides a physical basis for Darwin's natural selection phenomenon and helps explain some evolutionary trends that mere natural selection is not able to explain to this day: why some organisms have a characteristic X rather than Y is not due to the fact that X is better suited than Y but because the surrounding physical constraints makes that X is more likely to move towards maximum entropy than Y.

Let us now consider the following system:

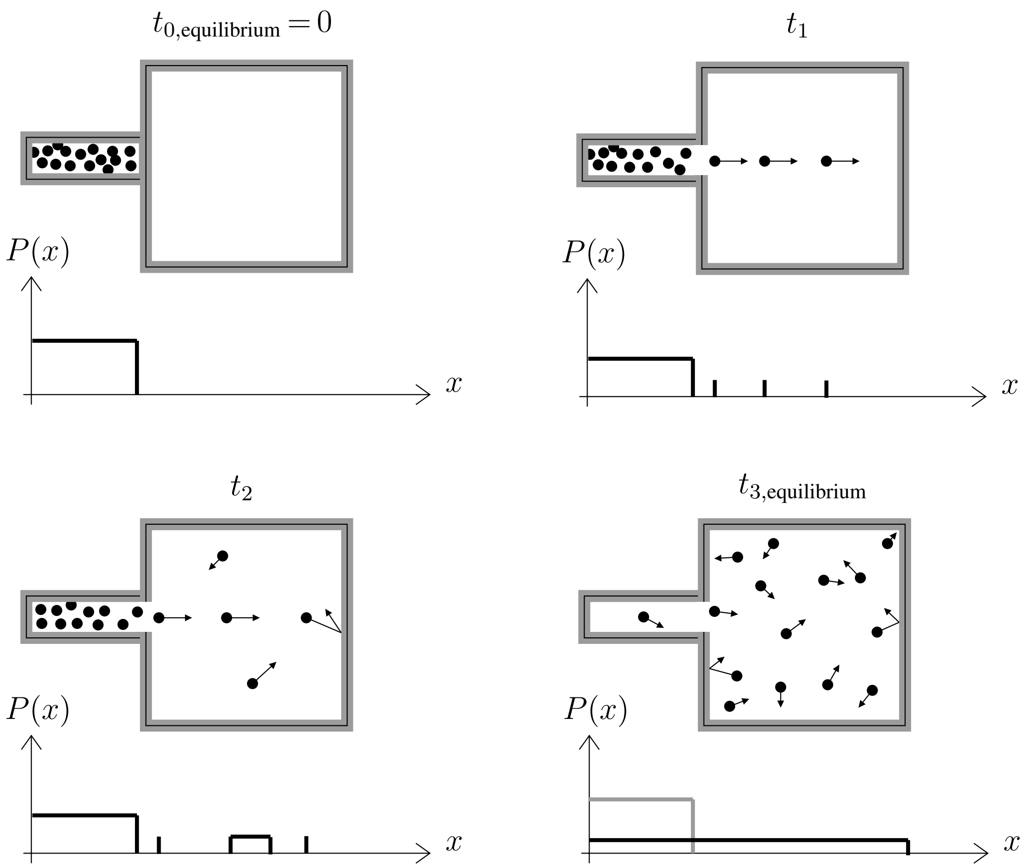

Figure 9.137: Example of change of entropy of a closed system

The distribution function $P(x)$ which describes the position of the particle along the x axis at the equilibrium $(t=0)$ will change to another distribution function corresponding to a new equilibrium at t_3. At equilibrium $P(x)$ is constant (uniformly distributed). But between the two equilibria, it evolves and becomes wider. So we lose the information on the position of particles. We can therefore re-state the second assumption, saying that a system that is out of equilibrium always operates in the sense of a loss of information (an enlargement of the corresponding probabilistic distribution function).

Meanwhile, the second principle of classical thermodynamics tells us that natural evolution must correspond to an increase of entropy $(\mathrm{d}S > 0)$. So there must be a close link between the information we have about the state of each particle and the entropy of the system.

The case we just described above shows clearly that the parameters or concepts: number of configurations, disorder, equilibrium, amount of information and entropy of an isolated system can be used to represent the state of a system. These parameters have the same function. Mathematical relations must therefore connect each other!

Let us recall that we have prove that the statistical information metric entropy of a system is given by:

$$S(X) = \mathrm{E}\{h(x)\} = -\lambda \sum_{i=1}^{n} p_i \log(p_i) \tag{9.5.119}$$

If we apply this relation to the case of a physical system in equilibrium for which we wish to calculate the entropy, we have proved earlier that:

$$p_1,p_2,\ldots,p_n=c^{te} \tag{9.5.120}$$

We still need to know what to what corresponds this constant probability. We have previously shown that at equilibrium, we had:

$$\Omega=\Omega_{\text{max}} \tag{9.5.121}$$

which is therefore the number of microstates at equilibrium. Thus, the probability of drawing a microstate among all of them is:

$$p=\frac{1}{\Omega_{\text{max}}} \tag{9.5.122}$$

that we simply write (a little dangerous ...) by tradition:

$$p=\frac{1}{\Omega} \tag{9.5.123}$$

We therefore have:

$$\begin{aligned}S&=-\lambda\sum_{i=1}^{n}p_i\log(p_i)=-\lambda\left(\frac{1}{\Omega}\log\left(\frac{1}{\Omega}\right)+\frac{1}{\Omega}\log\left(\frac{1}{\Omega}\right)+\ldots+\frac{1}{\Omega}\log\left(\frac{1}{\Omega}\right)\right)\\&=-\lambda\left(-\frac{1}{\Omega}\log(\Omega)-\frac{1}{\Omega}\log(\Omega)-\ldots-\frac{1}{\Omega}\log(\Omega)\right)=\lambda\log(\Omega)\left(\frac{1}{\Omega}+\frac{1}{\Omega}+\ldots+\frac{1}{\Omega}\right)\end{aligned} \tag{9.5.124}$$

As the probabilities of microstates are equally likely and that we sum over all of these, it comes:

$$\left(\frac{1}{\Omega}+\frac{1}{\Omega}+\ldots+\frac{1}{\Omega}\right)=1 \tag{9.5.125}$$

and therefore (without forgetting that in this special case the probabilities all have the same values!):

$$S=-\lambda\sum_{i=1}^{n}p_i\log(p_i)=\lambda\log(\Omega)=c^{te}\log(\Omega) \tag{9.5.126}$$

Since the equilibrium is related to the maximum disorder, and the disorder is related to the missing information, it seems reasonable to link the statistical entropy of information with statistical entropy of thermodynamics in physics. For this, we need that the constant allows us to get the right units and it comes naturally to choose this constant as it is equal to the Boltzmann constant k has the same units as the thermodynamic entropy. So:

$$S=k\log(\Omega) \tag{9.5.127}$$

We still have to choose the base of the logarithm. The experience shows that we must choose the natural logarithm that gives us the possibility to fall back on the results of Classical Mechanics after developments.

So we finally get the "Boltzmann law":

$$\boxed{S=k\ln(\Omega)} \tag{9.5.128}$$

which gives us the thermodynamic entropy of a system in equilibrium!

By the mathematical properties of the mean (see section Statistics page 571), especially the multiplication by a constant, we have for a set of N subsystems:

$$S(N\Omega)=NS(\Omega)=Nk\ln(\Omega)=-kN\sum_{i=1}^{n}p_i\log(p_i) \tag{9.5.129}$$

since as we pointed out earlier in our presentation of the Shannon formula, the entropy S is an expected mean (without forgetting that in this case the probabilities are of equal value!).

Before we continue we would like to quote John Wheeler because what he said in his book *Black Holes* is quite representative of the general trend of the physics of the 121st century (and some high level theories going also in this direction are quite promising):

quote

> ❞ *I think of my lifetime in physics as divided into three periods. In the first period... I was in the grip of the idea that Everything is Particles... I call my second period Everything is Fields. ... Now I am in the grip of a new vision, that Everything is Information* ❞
>
> John Archibald Wheeler

9.5.3 Statistical Physics Distributions

We will distinguish in this textbook 4 different statistics that come or not from quantum effects that will lead us to 4 well known distinct statistical distributions. These are the: Maxwell distribution, Maxwell-Boltzmann distribution, Fermi-Dirac distribution and Bose-Einstein distribution. They have numerous applications in physics as the black-body radiation that will be study in the section of Thermodynamics but also in Electrokinetic.

9.5.3.1 Maxwell Distribution (velocity distribution)

For a gas at equilibrium, let us ask the following question: What is the probability that a molecule has its velocity components between v_x and $v_x+\mathrm{d}x$, and v_y and $v_y+\mathrm{d}y$, and also v_z and $v_z+\mathrm{d}z$ in a conventional cartesian coordinate system?

This probability d^3P depends of $\vec{v}$ (that is to say of: (v_x,v_y,v_z)) and of $\mathrm{d}v_x,\mathrm{d}v_y,\mathrm{d}v_z$. It does not depend on the position of the molecule since the gas is assumed to equilibrium with respect to its center of mass!

We postulate in a first time that $\mathrm{d}P^3$ is proportional to each of the intervals $\mathrm{d}v_x,\mathrm{d}v_y,\mathrm{d}v_z$ such as:

$$\mathrm{d}^3P=f(\vec{v})\mathrm{d}v_x\mathrm{d}v_y\mathrm{d}v_z \tag{9.5.130}$$

and there is no preferred spatial directions. We can make a circular rotation of the Cartesian axes, the probability will be unchanged (isotropy of space).

The isotropy brings that the function $f(\vec{v})$ does not depend on vector $\vec{v}$, at best it dependent on the norm of the speed, such as:

$$\mathrm{d}^3P=f(v)\mathrm{d}v_x\mathrm{d}v_y\mathrm{d}v_z \tag{9.5.131}$$

Given $\mathrm{d}P_x$ (also often denoted $\mathrm{d}P(v_x)$ depending on the context) the probability for a molecule to have its component along the Ox axis between v_x and $v_x+\mathrm{d}v_x$ then:

$$\mathrm{d}P_x=\mathrm{d}P(v_x)=\varphi_x(v_x)\mathrm{d}v_x \tag{9.5.132}$$

also same with:

$$\mathrm{d}P_y=\mathrm{d}P(v_y)=\varphi_y(v_y)\mathrm{d}v_y \qquad \mathrm{d}P_z=\mathrm{d}P(v_z)=\varphi_z(v_z)\mathrm{d}v_z \tag{9.5.133}$$

The isotropy of space brings to write:

$$\varphi(v_x)=\varphi(v_y)=\varphi(v_z)=\varphi \tag{9.5.134}$$

The law of compound probabilities (see section Probabilities page 486) bring us to write:

$$\mathrm{d}^3P=\mathrm{d}P_x\mathrm{d}P_y\mathrm{d}P_z\Rightarrow f(v)=\varphi(v_x)\varphi(v_y)\varphi(v_z) \tag{9.5.135}$$

Determining the functions f and φ reveals within the following mathematical methodology:

$$\frac{\partial f}{\partial v_x}=\frac{\partial f}{\partial v}\frac{\partial v}{\partial v_x}=\frac{\partial}{\partial v_x}[\varphi(v_x)\varphi(v_y)\varphi(v_z)]=\varphi(v_y)\varphi(v_z)\frac{\mathrm{d}\varphi(v_x)}{\mathrm{d}v_x}=\frac{f}{\varphi(v_x)}\frac{\mathrm{d}\varphi(v_x)}{\mathrm{d}v_x} \tag{9.5.136}$$

Since:

$$v=\sqrt{v_x^2+v_y^2+v_z^2}\Rightarrow\frac{\partial v}{\partial v_x}=\frac{v_x}{\sqrt{v_x^2+v_y^2+v_z^2}}=\frac{v_x}{v} \tag{9.5.137}$$

Which gives us finally:

$$\frac{\mathrm{d}f}{\mathrm{d}v}\frac{\partial v}{\partial v_x}=\frac{v_x}{v}\frac{\mathrm{d}f}{\mathrm{d}v}=\frac{f}{\varphi(v_x)}\frac{\varphi(\mathrm{v_x})}{\mathrm{d}v_x}\Leftrightarrow\frac{1}{v}\frac{\mathrm{d}f}{\mathrm{d}v}=\frac{f}{v_x\varphi(v_x)}\frac{\mathrm{d}\varphi(v_x)}{\mathrm{d}v_x} \tag{9.5.138}$$

The left side of the last equality depends only on v, the right one only on v_x. The result can only be a constant that we will denote x_x. It follows that:

$$\frac{f}{v_x\varphi(v_x)}\frac{\mathrm{d}\varphi(v_x)}{\mathrm{d}v_x}=\alpha\leftrightarrow\frac{1}{\varphi(v_x)}\mathrm{d}\varphi(v_x)=\alpha v_x\mathrm{d}v_x \tag{9.5.139}$$

By integrating:

$$\int\frac{1}{\varphi(v_x)}\mathrm{d}\varphi(v_x)=\ln(\varphi(v_x))+c_1^{te}=\int\alpha v_x\mathrm{d}v_x=\frac{\alpha}{2}v_x^2+c_2^{te} \tag{9.5.140}$$

Therefore:

$$\ln(\varphi(v_x))=\frac{\alpha}{2}v_x^2+(c_2^{te}-c_1^{te})=\frac{\alpha}{2}v_x^2+c^{te} \tag{9.5.141}$$

and let us put $c^{te}=\ln(A)$. It comes therefore:

$$\ln(\varphi(v_x))=\frac{\alpha}{2}v_x^2+\ln(A)\Rightarrow\ln\left(\frac{\varphi(v_x)}{A}\right)=\frac{\alpha}{2}v_x^2\Rightarrow\varphi(v_x)=Ae^{\frac{\alpha}{2}v_x^2} \tag{9.5.142}$$

Identically, we have:

$$\varphi(v_x)=Ae^{\frac{\alpha}{2}v_x^2}\qquad\varphi(v_y)=Ae^{\frac{\alpha}{2}v_y^2}\qquad\varphi(v_z)=Ae^{\frac{\alpha}{2}v_z^2} \tag{9.5.143}$$

The law of compound probabilities involving:

$$f(v)=\varphi(v_x)\varphi(v_y)\varphi(v_z) \tag{9.5.144}$$

We finally have:

$$f(v)=A^3e^{\frac{\alpha}{2}(v_x^2+v_y^2+v_z^2)}=A^3e^{\frac{\alpha v^2}{2}} \tag{9.5.145}$$

Let us notice that α is necessarily negative otherwise the probability for a molecule to have an infinite velocity component would be infinite which would mean that all the molecules will have an infinite velocity and therefore an infinite energy!!!

We put:

$$\frac{\alpha}{2}=-B \tag{9.5.146}$$

with $B>0$.

Finally, it comes:

$$\mathrm{d}^3P=\mathrm{d}P_x\mathrm{d}P_y\mathrm{d}P_z=A^3e^{-Bv^2}\mathrm{d}v_x\mathrm{d}v_y\mathrm{d}v_z \tag{9.5.147}$$

It remains to us to normalize A. The probability of a molecule having a velocity component between speed $[-\infty,+\infty]$ or a velocity norm between $[0,+\infty]$ is equal to 1 (100% chance). So using exactly the same method computation than that seen in the section Statistics for the Normal distribution (see page 695), we have:

$$\int\limits_{-\infty}^{+\infty}\mathrm{d}P(v_x)=\int\limits_{-\infty}^{+\infty}Ae^{-Bv_x^2}\mathrm{d}v_x=A\int\limits_{-\infty}^{+\infty}e^{-Bv_x^2}\mathrm{d}v_x=1=A\sqrt{\frac{\pi}{B}}\Rightarrow A=\sqrt{\frac{B}{\pi}} \tag{9.5.148}$$

We have so far spoken in terms of probabilities. An equivalent language is to seek in a box containing N molecules, the number $\mathrm{d}N$ of molecules having given characteristics, that is to say for example, the number of molecules $\mathrm{d}N(v_x)$ having a velocity component between v_x and $v_x+\mathrm{d}v_2$. This number being obviously equal in one dimension to:

$$\mathrm{d}N(v_x)=N\mathrm{d}P_x=NA^{-Bv_x^2}\mathrm{d}v_x \tag{9.5.149}$$

More generally:

$$\mathrm{d}N(v)=N\mathrm{d}^3P=N\left(\frac{B}{\pi}\right)^{3/2}e^{-Bv^2}\mathrm{d}v_x\mathrm{d}v_y\mathrm{d}v_z \tag{9.5.150}$$

To get $\mathrm{d}P$ we put ourselves in the configuration space of velocities that is to say, in a Cartesian coordinate system of coordinates $(\mathrm{O}, v_x, v_y, v_z)$. The components (v_x, v_y, v_z) are not independent as related by the relation:

$$v = v_x^2 + v_y^2 + v_z^2 \tag{9.5.151}$$

The extremity of the velocity vectors $\vec{v}$ having a velocity norm of v, that is to say of velocity components bounded as the relation above, is in velocity space of configuration on a sphere of radius v. It will be the same for velocity vectors of having a norm equal to $v + \mathrm{d}v$.

In the velocity space configuration, we outline a portion of space between the sphere of radius v and the sphere of radius $v + \mathrm{d}v$, equal in volume to $4\pi v^2 \mathrm{d}v^2$.

The probability $\mathrm{d}P^3$ is proportional to $\mathrm{d}v_x \mathrm{d}v_y \mathrm{d}v_z$ that is to say to the elementary volume in the velocity configuration space. To get $\mathrm{d}P(v)$, we must integrate $\mathrm{d}P^3$ at all possible speeds vectors, that is to say having their extremities between the two spheres. This integration is particularly simple because the norm of $\vec{v}$ in this configuration space (inter-volume) is constant. So we get:

$$\mathrm{d}P(v) = \left(\frac{B}{\pi}\right)^{3/2} e^{-Bv^2} 4\pi v^2 \mathrm{d}v \tag{9.5.152}$$

and therefore, in a box containing N molecules, the number of molecules $\mathrm{d}N(v)$ have a norm between v and $v + \mathrm{d}v$ is equal to:

$$\mathrm{d}N(v) = N\mathrm{d}P(v) \tag{9.5.153}$$

Let us recall now that according to what we have studied in the section Statistics, the average value $\langle G \rangle$ of a quantity G is the product of G by all the probabilities of G integrated with all possible values of this quantity such that in one dimension we have (according to the x axis):

$$\begin{aligned}\langle v_x^2 \rangle &= \int_0^{+\infty} v_x^2 \mathrm{d}P(v_x) = \left(\frac{B}{\pi}\right)^{1/2} \int_0^{+\infty} v_x^2 e^{-Bv_x^2} \mathrm{d}v_x = \left(\frac{\sqrt{\pi}\operatorname{erf}(\sqrt{B}v_x)}{4B^{3/2}} - \frac{v_x e^{-Bv_x^2}}{2B}\right)\Bigg|_0^{+\infty} \\ &= \left(\frac{B}{\pi}\right)^{1/2} \frac{\sqrt{\pi}}{4B^{3/2}} = \frac{1}{4B}\end{aligned} \tag{9.5.154}$$

where the integral is calculated by making the change $v_x^2 = x$ and where we have then used an integration by parts (for the erf function see page 3697).

We have respectively generally :

$$\begin{aligned}\langle v^2 \rangle &= \int_0^{+\infty} v^2 P(v) \mathrm{d}v = 4\pi \left(\frac{B}{\pi}\right)^{3/2} \int_0^{+\infty} v^4 e^{-Bv^2} \mathrm{d}v = \left(\frac{3\sqrt{\pi}\operatorname{erf}(\sqrt{B}v)}{8B^{5/2}} - \frac{ve^{-Bv^2}(2Bv^2+3)}{4B^2}\right)\Bigg|_0^{+\infty} \\ &= 4\pi \left(\frac{B}{\pi}\right)^{3/2} \frac{3\sqrt{\pi}}{8B^{5/2}} = \frac{3}{2B}\end{aligned} \tag{9.5.155}$$

where the integral has been calculated in the same manner.

Therefore:

$$\langle v_x^2\rangle = \langle v_y^2\rangle = \langle v_z^2\rangle = \frac{1}{2B} \tag{9.5.156}$$

or:

$$\langle v_x^2\rangle + \langle v_y^2\rangle + \langle v_z^2\rangle = \frac{3}{2B} \tag{9.5.157}$$

Thermodynamics or Fluid Mechanics (see virial theorem page 3897) gives us for a perfect monoatomic gas (see the sections of Continuum Mechanics and Thermodynamics) of constant heat capacity and volume:

$$E_c = \frac{3}{2}NkT \tag{9.5.158}$$

If we hypothesize that the part of the energy associated with the temperature is due to the kinetic motion of molecules, we can write:

$$E_c = \frac{3}{2}NkT := N\frac{1}{2}m\langle v^2\rangle \Rightarrow \langle v^2\rangle = \frac{3kT}{m} \tag{9.5.159}$$

We then define the "average thermal velocity" or "root-mean-square (rms) speed":

$$\boxed{\langle v_{\text{th}}\rangle = \sqrt{\langle v^2\rangle} = \sqrt{\frac{3kT}{m}}} \tag{9.5.160}$$

A numerical application (the corresponding integral cannot be solved in closed form) for the electron in the case of semiconductors (where we approximate some relations by the Maxwell-Boltzmann distribution) gives an average thermal velocity at room temperature of $120,000\,[\text{m}\cdot\text{s}^{-1}]$.

But to return to our distribution .... So we have:

$$\langle v^2\rangle = \frac{3}{2B} = \frac{3kT}{m} \Rightarrow B = \frac{m}{2kT} \tag{9.5.161}$$

Then we finally have:

$$\boxed{\mathrm{d}P(v) = 4\pi v^2\left(\frac{m}{2\pi kT}\right)^{3/2} e^{-\frac{m}{2kT}v^2}\mathrm{d}v} \tag{9.5.162}$$

that is the velocity distribution in a monoatomic gas which plot looks like (the units in ordinate axes are arbitrary):

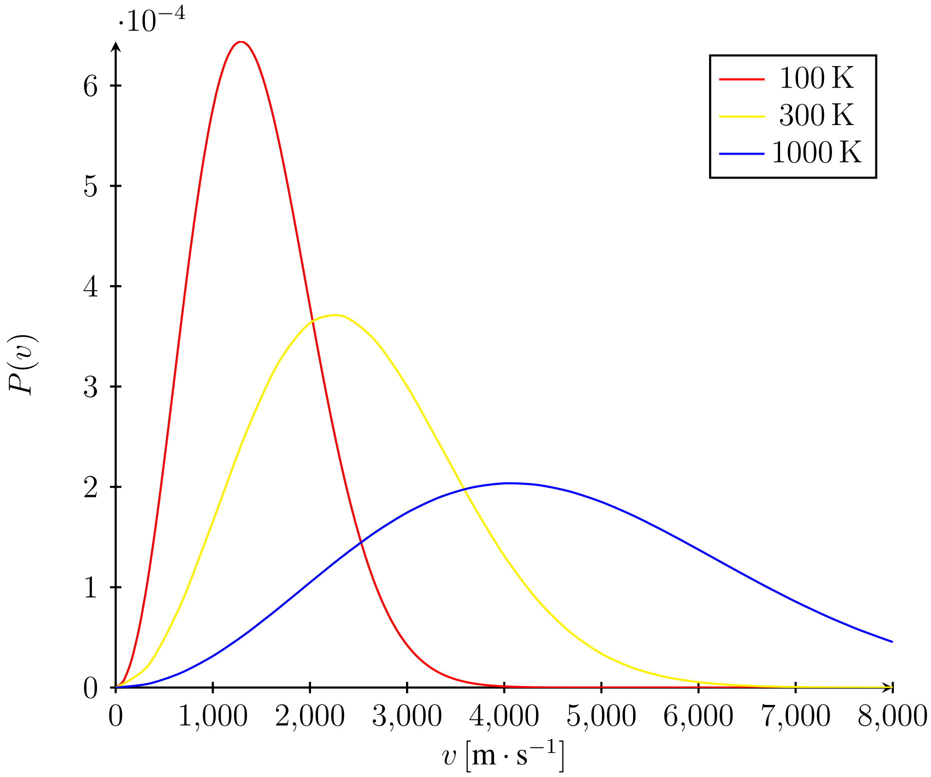

Figure 9.138: **Maxwell velocity distribution for a monoatomic ideal gas (author: Janosh Riebesell)**

Using the fact that $E=1/2mv^2$ (and therefore $E=mv\mathrm{d}v$) the previous relation is often used in the following shape:

$$\mathrm{d}P(E)=\frac{2}{\sqrt{\pi}}\frac{E^{1/2}}{(kT)^{3/2}}e^{-\frac{E}{kT}}\mathrm{d}E \qquad (9.5.163)$$

The previous relation thus gives the proportion of gas molecules having at a given time t a velocity v. We see that the probability density extends to infinity and we find a non-zero probability (approaching zero) that the particle have extremely high speed. In fact, if we have a system of identical particles at the same temperature T, then we will find a small given number of them with these very high speeds. At the heart of the stars it is these rare and very fast particles that are able to overcome the Coulomb repulsion between the nuclei and make them approach one another to initiate nuclear fusion mechanism which is the source energy of the star.

We get then for a single spatial direction and using a common notation in the English literature (by adopting the preceding developments we fall relatively easily on this result) the following distribution function:

$$f(v)=4\pi v^2\left(\frac{m}{2\pi kT}\right)^{3/2}e^{-\frac{m}{2kT}v^2} \qquad (9.5.164)$$

and for the three spatial dimensions still using the notation common in English literature (some terms are simply placed under the root):

$$f(v)=\sqrt{\frac{2}{\pi}\left(\frac{m}{kT}\right)^3}v^2e^{-\frac{m}{2kT}v^2} \qquad (9.5.165)$$

So this distribution function gives us the possibility to define the most likely velocity (the "modal" value as we say in statistics) sometimes denoted v_m, which is the maximum of the curve $f(v)$, or where the first derivative is equal to zero. Thus, for a single spatial dimension we have for the proportion of gas molecules:

$$\begin{aligned}\frac{\partial f(v)}{\partial v}&=\frac{\partial}{\partial v}\left(4\pi v^2\left(\frac{m}{2\pi kT}\right)^{1/2}e^{-\frac{mv^2}{2kT}}\right)\\&=8\pi v\left(\frac{m}{2\pi kT}\right)^{1/2}e^{-\frac{mv^2}{2kT}}-8\frac{8}{2kT}\pi v^3\left(\frac{m}{2\pi kT}\right)^{1/2}e^{-\frac{mv^2}{2kT}}\\&=8\pi v\left[1-\frac{2}{2kT}v^2\right]\left(\frac{m}{2\pi kT}\right)^{1/2}e^{-\frac{mv^2}{2kT}}=0\end{aligned}\tag{9.5.166}$$

Therefore (you notice that the result would have been the same if we had taken all spatial dimensions ... which is consistent!):

$$\begin{aligned}1-\frac{m}{2kT}v^2&=0\\\Rightarrow\frac{m}{2kT}v^2&=1\\\Rightarrow v^2&=\frac{2kT}{m}\end{aligned}\tag{9.5.167}$$

hence the most likely speed in one dimension (caution! this is not the maximum speed since we know that the distribution extends to the infinite speed):

$$v=\sqrt{\frac{2kT}{m}}\tag{9.5.168}$$

For the average speed (the mean) and using directly all spatial dimensions we have:

$$\begin{aligned}\bar{v}=\mathrm{E}(v)=\int_0^{+\infty}vf(v)\mathrm{d}v&=\int_0^{+\infty}v4\pi v^2\left(\frac{m}{2\pi kT}\right)^{3/2}e^{-\frac{mv^2}{2kT}}\mathrm{d}v\\=4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}&\int_0^{+\infty}v^3e^{-\frac{m}{2kT}v^2}\mathrm{d}v\end{aligned}\tag{9.5.169}$$

We then have an integral of the type:

$$\int_0^{+\infty}x^3e^{-ax^2}\mathrm{d}x\tag{9.5.170}$$

The best is to decompose $x^3e^{-ax^2}$ in $x^2xe^{-ax^2}$ and then we integrate by parts. Then we have:

$$\int_0^{+\infty}x^2\left(xe^{-ax^2}\right)\mathrm{d}x=\underbrace{-x^2\frac{1}{2a}e^{-ax^2}\Big|_0^{+\infty}}_{=0}+\int_0^{+\infty}2x\frac{1}{2a}e^{-ax^2}\mathrm{d}x\tag{9.5.171}$$

The last integral is easily calculable. This is the same as the one we already solved in the section Statistics for our introduction of the Normal law (see page 695). So:

$$\int_0^{+\infty}\frac{1}{a}xe^{-ax^2}\mathrm{d}x=\frac{1}{a}\left(-\frac{1}{2a}e^{-ax^2}\Big|_0^{+\infty}\right)=\frac{1}{2a^2}\tag{9.5.172}$$

Therefore it comes:

$$\begin{aligned}\bar{v}&=4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\int\limits_0^{+\infty}v^3e^{-\frac{m}{2kT}v^2}\mathrm{d}v=4\pi\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{1}{2\left(\frac{m}{2kT}\right)^2}\\&=\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{8\pi k^2T^2}{m^2}=\sqrt{\frac{8kT}{\pi m}}\end{aligned} \tag{9.5.173}$$

but this time the result is dependent on the number of spatial dimensions that we take!

9.5.3.2 Maxwell-Boltzmann Distribution

In corpuscular quantum physics, we learn that the energy of a particle is quantized, that is, the possible values for the energy form a discrete spectrum (see section Corpuscular Quantum Physics page 4627). Even if, in a number of common situations, for a particle and even more for a system consisting of a large number of particles, the energy levels are so tight that we can handle, mathematically, this spectrum as being continuous ("continuum approximation"), the fact remains that they are rigorously quantified. This quantified approach of physical distributions at the corpuscular level of the material is often referred as "quantum statistics".

A particle having a level of energy E_i, can be in different sub-states.

We know (we did not use the Schrödinger equation in the section of Corpuscular Quantum Physics to prove this strictly) that, to describe an atom, we introduce four quantum numbers, namely:

1. the principal quantum number that quantifies energy $n=n_r+n_\theta$
2. the azimuthal quantum number that quantifies the momentum n_θ
3. the quantum magnetic number that quantifies the magnetic moment m_l
4. the tree spin that quantifies the "proper rotation" (...) of the electrons s

Thus for a same energy (for a particular value of the principal quantum number), an atom or an electron can have different values of the secondary, magnetic or spin quantum numbers.

To qualify the possibility of sub-states corresponding to a same energy, we use the term "degeneration" and we translate by the variable g_i the number of degeneration corresponding to the same level of energy E_i.

We will consider a system of N particles that are placed on K different energy levels E_i. We find n_i particles on the energy level E_i. We then always have the following relations for the total energy (which we denote by the same letter as that used in thermodynamics) and for the number of particles:

$$\begin{aligned}&\sum_{i=1}^{K} n_i E_i = U\\&\sum_{i=1}^{K} n_i = N \Rightarrow \sum_{i=1}^{K} \mathrm{d}n_i = 0\end{aligned} \tag{9.5.174}$$

We will assume (this is important) these quantities as being constant and that the system is completely determined by the distribution $\{n_i\}$ of the particles on the K different energy levels.

It exist many possible microscopic configurations - also named "complexion" - Ω that are compatible with the distribution $\{n_i\}$. Their number is given by (see permutations with repetition in the section of Probabilities page 525):

$$\Omega = \frac{N!}{n_1!n_2!\ldots n_K!} \tag{9.5.175}$$

But we have neglected the possible degeneration of the levels i. If there exist g_i sublevels with an energy E_i, we have then:

$$\Omega = N!\frac{g_1^{n_1}g_2^{n_2}\ldots g_K^{n_K}}{n_1!n_2!\ldots n_K!} = N!\prod_i \frac{g_i^{n_i}}{n_i!} \tag{9.5.176}$$

This can be checked with the following figure depicting a unique energy level for two distinguishable particles having three possible (quantum) states (i.e. sublevels):

$$\Omega_{\text{M.B.}} = N!\frac{g^n}{n!} = 2!\frac{3^2}{2!} = 9$$

Example:
2 particles: A and B
3 states: 1, 2 and 3

9 distinct states

1	2	3
AB	$\ldots$	$\ldots$
$\ldots$	AB	$\ldots$
$\ldots$	$\ldots$	AB
A	B	$\ldots$
B	A	$\ldots$
A	$\ldots$	B
B	$\ldots$	A
$\ldots$	A	B
$\ldots$	B	B

Discernable ($A \neq B$)

Figure 9.139: $\Omega_{\text{M.B.}}$ **states in the Maxwell-Boltzmann distribution**

Remark

The number g_i is then the degeneration of the energy state E_i, i.e. the number of states with this energy.

Taking the logarithm, it comes:

$$\ln(\Omega)=\ln(N!)+\sum_{i=1}^{K}(n_i\ln(g_i)-\ln(n_i!)) \tag{9.5.177}$$

and using Stirling's formula (see section Numerical Methods page 6301):

$$n!=e^{n\ln(n)}e^{-n}\Rightarrow\ln(n!)\cong n\ln(n)-n \tag{9.5.178}$$

keeping in mind that the latter is a rough approximation for smaller values of n but becomes an acceptable approximation for n greater than $1,000$. Then we can write:

$$\ln(\Omega)=N\ln(N)-N+\sum_{i=1}^{K}(n_i\ln(g_i)-n_i\ln(n_i)+n_i)=N\ln(N)+\sum_{i=1}^{K}n_i\ln\left(\frac{g_i}{n_i}\right) \tag{9.5.179}$$

We now look for the most probable distribution, that is to say one that maximizes Ω (and thus that implicitly maximizes entropy as it can only increase as show us every day life experience so far for an isolated system). To find the extremum, we will differentiate this expression such that:

$$\frac{\partial\ln(\Omega)}{\partial n_i}=0 \tag{9.5.180}$$

so all other parameters other than n_i are fixed.

But, as:

$$\begin{gathered}\sum_{i=1}^{K}n_iE_i=U\Leftrightarrow U-\sum_{i=1}^{K}n_iE_i=0\Leftrightarrow\beta\left(U-\sum_{i=1}^{K}n_iE_i\right)=0\\ \sum_{i=1}^{K}n_i=N\Leftrightarrow N-\sum_{i=1}^{K}n_i=0\Leftrightarrow\alpha\left(N-\sum_{i=1}^{K}n_i\right)=0\end{gathered} \tag{9.5.181}$$

where α,β are constants that help to ensure consistency of dimensional analysis (in other words: that the units are coherent ...).

It is therefore equivalent and necessary to take into account also these intrinsic parameters (the fact to in such a clever way null terms is named "method of Lagrange multipliers" as seen in the section of Theoretical Computing) to write:

$$\frac{\partial\ln(\Omega)}{\partial n_i}=0 \tag{9.5.182}$$

in a more complete form below:

$$\frac{\partial}{\partial n_i}\left(\ln(\Omega)+\alpha\left(N-\sum_{i=1}^{K}n_i\right)+\beta\left(U-\sum_{i=1}^{K}n_iE_i\right)\right)=0 \tag{9.5.183}$$

So after rearrangement:

$$\frac{\partial \ln(\Omega)}{\partial n_i}=-\frac{\partial}{\partial n_i}\left[\alpha\left(N-\sum_{i=1}^{K}n_i\right)+\beta\left(U-\sum_{i=1}^{K}n_iE_i\right)\right] \tag{9.5.184}$$

giving after a first simplification (elimination of the derivative of constants):

$$\frac{\partial \ln(\Omega)}{\partial n_i}=\frac{\partial}{\partial n_i}\left[\alpha\sum_{i=1}^{K}n_i+\beta\sum_{i=1}^{K}n_iE_i\right]=\frac{\partial}{\partial n_i}\sum_{i=1}^{K}\left[\alpha n_i+\beta n_iE_i\right] \tag{9.5.185}$$

Which brings us to write (since all the terms of the sum indexed on a different value i from that of the partial derivative are equal zero):

$$\frac{\partial \ln(\Omega)}{\partial n_i}\frac{\partial}{\partial n_i}(\alpha n_i+\beta n_iE_i)=\alpha+\beta E_i \tag{9.5.186}$$

Which gives us finally:

$$\frac{\partial \ln(\Omega)}{\partial n_i}=\alpha+\beta E_i \tag{9.5.187}$$

which will also therefore have to be equal zero. Thus, we have cleverly show a result which is nonetheless very powerful. By imposing to maximize the entropy we revealed two terms (each including a constant that we will have to determine later!) and whose sum has to be equal zero to ensure the experimental validity of theoretical model when the entropy of the isolated system is maximal.

But this latter relation is equivalent as to seek (which will be very useful later!):

$$\mathrm{d}\ln(\Omega)=\mathrm{d}\left(N\ln(N)+\sum_{i=1}^{K}n_i\ln\left(\frac{g_i}{n_i}\right)\right)=0 \tag{9.5.188}$$

Indeed, let's use again the clever method of Lagrange multipliers as seen in the section of Theoretical Computing (adding zero terms assuming energy levels E_i and the number degeneration g_i as fixed) and remembering (see section Differential and Integral Calculus page 1534) that :

$$\frac{\mathrm{d}\left(x\ln\left(\frac{a}{x}\right)\right)}{\mathrm{d}x}=\ln\left(\frac{a}{x}\right)-1\Leftrightarrow \mathrm{d}\left(x\ln\left(\frac{a}{x}\right)\right)=\ln\left(\frac{a}{x}\right)\mathrm{d}x-\mathrm{d}x \tag{9.5.189}$$

Therefore we have:

$$\begin{aligned}
&\mathrm{d}\left(N\ln(N)+\sum_{i=1}^{K}n_i\ln\left(\frac{g_i}{n_i}\right)+\alpha\left(N-\sum_{i=1}^{K}n_i\right)+\beta\left(U-\sum_{i=1}^{K}n_iE_i\right)\right)=0\\
&\Rightarrow\sum_{i=1}^{K}\mathrm{d}n_i\ln\left(\frac{g_i}{n_i}\right)-\underbrace{\sum_{i=1}^{K}\mathrm{d}n_i}_{\to 0}-\alpha\sum_{i=1}^{K}\mathrm{d}n_i-\beta\sum_{i=1}^{K}E_i\mathrm{d}n_i=\sum_{i=1}^{K}\left[\left(\ln\left(\frac{g_i}{n_i}\right)-\alpha-\beta E_i\right)\mathrm{d}n_i\right]=0\\
&\Rightarrow\left(\ln\left(\frac{g_i}{n_i}\right)-\alpha-\beta E_i\right)\mathrm{d}n_i=0\\
&\Rightarrow\ln\left(\frac{g_i}{n_i}\right)=\alpha+\beta E_i\\
&\Rightarrow\ln\left(\frac{n_i}{g_i}\right)=-\alpha-\beta E_i
\end{aligned} \tag{9.5.190}$$

Therefore (relation often named "Boltzmann distribution"):

$$n_i = g_i e^{-\alpha-\beta E_i} \tag{9.5.191}$$

Let us recall that we have for the entropy of a system:

$$S = k\ln(\Omega) \tag{9.5.192}$$

and therefore:

$$\mathrm{d}S = k\mathrm{d}(\ln(\Omega)) = k\sum_i \frac{\partial \ln(\Omega)}{\partial n_i}\mathrm{d}n_i \tag{9.5.193}$$

and as:

$$\frac{\partial \ln(\Omega)}{\partial n_i} = \alpha + \beta E_i \tag{9.5.194}$$

Then we have:

$$\frac{\mathrm{d}S}{k} = \sum_{i=1}^{K}(\alpha+\beta E_i)\mathrm{d}n_i = \alpha\sum_{i=1}^{K}\mathrm{d}n_i + \beta\sum_{i=1}^{K}E_i\mathrm{d}n_i = \alpha\mathrm{d}N + \beta\mathrm{d}U \tag{9.5.195}$$

Thermodynamics leads us to (see section Thermodynamics page 3660):

$$\mathrm{d}U = T\mathrm{d}S + \sum_{i=1}^{K}\mu_i\mathrm{d}N_i \tag{9.5.196}$$

So we see appearing the chemical potential μ which has an influences when the number of particles considered varies (i.e. the chemical potential is defined as the change in the system energy on adding a particle).

If all the particles (or particle groups) are identical $\mu_i = c^{te} = \mu$ thus:

$$\mathrm{d}U = T\mathrm{d}S + \mu\sum_{i=1}^{K}\mathrm{d}N_i = T\mathrm{d}S + \mu\mathrm{d}N \tag{9.5.197}$$

Which finally bring us to:

$$\frac{\mathrm{d}S}{k} = \frac{\mathrm{d}U}{kT} - \frac{\mu}{kT}\mathrm{d}N \tag{9.5.198}$$

and bring is to identify:

$$\frac{\mathrm{d}S}{k} = \frac{\mathrm{d}U}{kT} - \frac{\mu}{kT}\mathrm{d}N \equiv \beta\mathrm{d}U + \alpha\mathrm{d}N \tag{9.5.199}$$

and therefore:

$$\alpha = -\frac{\mu}{kT} \quad \text{and} \quad \beta = \frac{1}{kT} \tag{9.5.200}$$

We can then rewrite the relation:

$$n_i = g_i e^{-\alpha-\beta E_i} \tag{9.5.201}$$

in the final traditional form of "Maxwell-Boltzmann function":

$$\boxed{n_i=g_ie^{-\frac{E_i+\mu}{kT}}=g_ie^{\frac{\mu}{kT}}e^{\frac{-E_i}{kT}}} \tag{9.5.202}$$

where $e^{\frac{-E_i}{kT}}$ is often named the "Boltzmann factor".

Example:

In a sample at room temperature (about $300\,[\text{K}]$), almost all atoms are in their electronic ground state. For example, if the first excited state is $1\,[\text{eV}]$ above the ground state, the Boltzmann factor is:

$$e^{-E/kT}=e^{-\frac{1.6\cdot 10^{-19}\,[\text{J}]}{(1.4\cdot 10^{-25}\,[\text{J}\cdot\text{K}^{-1}])(300\,[\text{K}])}}=e^{-38}=3\cdot 10^{-17}$$

This extremely tiny number represents the fact that at room temperature an insignificant fraction of the atoms will be excited thermally to $1\,[\text{eV}]$ above the ground state. Therefore, it is reasonable to assume that essentially all the atoms in an ordinary room-temperature absorption measurement start out in the electronic ground state.

On the other hand, the surface temperature of the Sun (actually a G2V-type star, aka yellow dwarf) is about $5,000\,[\text{K}]$, and with $E=1\,[\text{eV}]$ the Boltzmann factor is $e^{-E/kT}=e^{-2.3}=0.1$, so a sizable fraction of atoms can be in an excited state $1\,[\text{eV}]$ above the ground state, due to thermal excitation.

That we find most frequently in the literature as follows:

$$\boxed{n_i=g_ie^{\frac{\mu-E_i}{kT}}} \tag{9.5.203}$$

and especially in this form:

$$\boxed{f_{MB}(E,T,\mu)=e^{\frac{\mu-E_i}{kT}}} \tag{9.5.204}$$

We will use this relation in our study of semiconductor theory (see section Electrokinetics page 4279) as well as in our study of plasmas (see section Continuum Mechanics page 3945).

As $N=\sum_{i=1}^{K}n_i$, we have:

$$N=e^{\frac{\mu}{kT}}\sum_{i=1}^{K}g_ie^{\frac{-E_i}{kT}} \tag{9.5.205}$$

We can then calculate n_i/N and we get the discrete formulation of the "Maxwell-Boltzmann statistics":

$$\boxed{P=\frac{n_i}{N}=\frac{g_ie^{\frac{-E_i}{kT}}}{\sum\limits_{i=1}^{K}g_ie^{\frac{-E_i}{kT}}}} \tag{9.5.206}$$

This relation therefore gives the ratio (or "proportion" or "probability") between the number of particles which by hypothesis does not interact with each other (otherwise the model is too complex) in a given energy state E_i and the number of particles that do not interact with each other and can take different discrete energy states E_i. Thus, knowing N, it is possible using this relation to know the proportion of particles in a particular energy state. Obviously, if there is only one sub energy level, this relation reduces to (it is also in this form that we find it often in the literature):

$$P=\frac{n_i}{N}=\frac{e^{\frac{-E_i}{kT}}}{\sum\limits_{i=1}^{K} e^{\frac{-E_i}{kT}}} \tag{9.5.207}$$

Remark

The Maxwell-Boltzmann statistics applies in the absence of interaction between particles and is therefore valid for an ideal gas, but does not apply, for example, for a liquid. Moreover, it applies only to high temperatures when quantum effects are negligible. At low temperatures we use the Bose-Einstein statistics for bosons (referring to the name of Bose...) and the Fermi-Dirac statistics for fermions (referring to the name of Fermi...) that we will study and prove further below.

We name the term in the denominator, the "canonical partition function". It is most often denoted Z_c such that:

$$P=\frac{n_i}{N}=\frac{e^{\frac{-E_i}{kT}}}{Z_c} \tag{9.5.208}$$

and defined in the most general case by:

$$Z_c=\sum_{i=1}^{K} g_i e^{-\beta E_i} \tag{9.5.209}$$

Therefore (obvious):

$$\frac{n_i}{N}=\frac{e^{\frac{-E_i}{kT}}}{Z_c} \Leftrightarrow n_i=\frac{N}{Z}g_i e^{-\beta E_i} \tag{9.5.210}$$

The microcanonical, canonical and grand canonical sets correspond to systems subject to various constraints which are respectively:

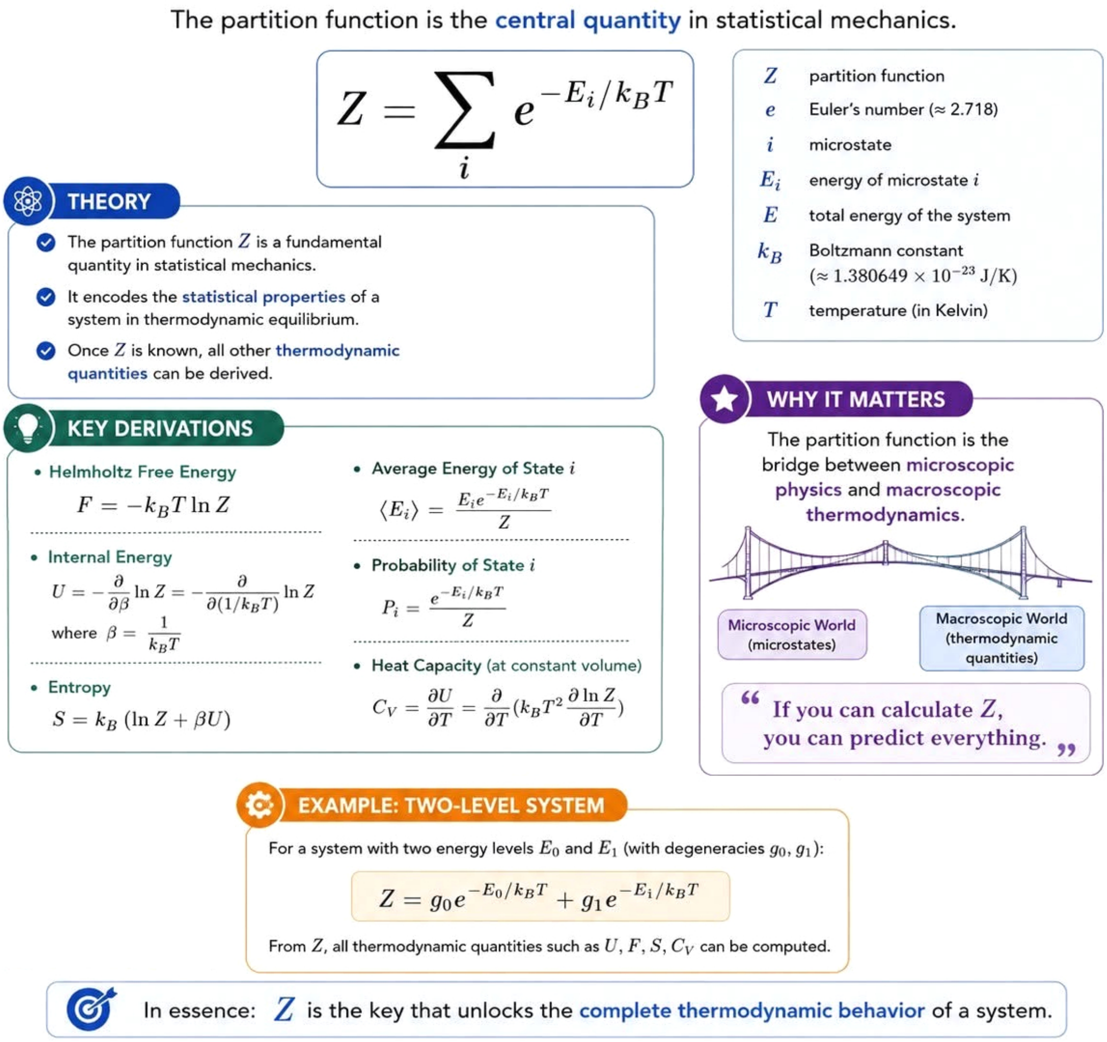
- Microcanonical: fixed energy, fixed number of particles, fixed volume
- Canonical: fixed mean energy = fixed temperature, fixed number of particles, fixed volume
- Grand canonical: fixed mean energy = temperature fixed, average number of particles fixed = fixed chemical potential[21], fixed volume

---

[21] Let us remind that the chemical potential is defined as the change in the system energy on adding a particle

This is true in quantum physics as in classical physics.

Here is an infographic summarizing the future implications of this canonical partition function, which we will demonstrate in detail later in this textbook.



The partition function is the **central quantity** in statistical mechanics.

$$Z=\sum_i e^{-E_i/k_BT}$$

Z	partition function
e	Euler's number (≈ 2.718)
i	microstate
E_i	energy of microstate i
E	total energy of the system
k_B	Boltzmann constant ($\approx 1.380649\times 10^{-23}\,\mathrm{J/K}$)
T	temperature (in Kelvin)

THEORY

- ✓ The partition function Z is a fundamental quantity in statistical mechanics.
- ✓ It encodes the **statistical properties** of a system in thermodynamic equilibrium.
- ✓ Once Z is known, all other **thermodynamic quantities** can be derived.

KEY DERIVATIONS

- **Helmholtz Free Energy**

$$F=-k_BT\ln Z$$

- **Internal Energy**

$$U=-\frac{\partial}{\partial\beta}\ln Z=-\frac{\partial}{\partial(1/k_BT)}\ln Z$$

where $\beta=\dfrac{1}{k_BT}$

- **Entropy**

$$S=k_B\left(\ln Z+\beta U\right)$$

- **Average Energy of State i**

$$\langle E_i\rangle=\frac{E_ie^{-E_i/k_BT}}{Z}$$

- **Probability of State i**

$$P_i=\frac{e^{-E_i/k_BT}}{Z}$$

- **Heat Capacity** (at constant volume)

$$C_V=\frac{\partial U}{\partial T}=\frac{\partial}{\partial T}(k_BT^2\frac{\partial\ln Z}{\partial T})$$

WHY IT MATTERS

The partition function is the bridge between **microscopic physics** and **macroscopic thermodynamics**.

> "If you can calculate Z, you can predict everything."

EXAMPLE: TWO-LEVEL SYSTEM

For a system with two energy levels E_0 and E_1 (with degeneracies g_0, g_1):

$$Z=g_0e^{-E_0/k_BT}+g_1e^{-E_1/k_BT}$$

From Z, all thermodynamic quantities such as U, F, S, C_V can be computed.

In essence: Z is the key that unlocks the **complete thermodynamic behavior** of a system.

9.5.3.3 Boltzmann Distribution

Let us now see a first interesting application of the Maxwell-Boltzmann distribution function.

Consider the interesting case where :

- The volume and number of particles are fixed (microcanonical system)
- The fact that the number of particles is fixed, the chemical potential[22] is zero
- A temperature high enough so that the energy states are in endless quantity

---

[22] Let us remind that the chemical potential is defined as the change in the system energy on adding a particle.

It is quite obvious that if the energy states are in infinite quantity, the degeneration factor g_i will be equal to the unit (because there is no place for degeneration levels other than the level itself).

We then have the Maxwell-Boltzmann distribution that becomes in theses condition the "Boltzmann distribution":

$$P=\frac{e^{-\frac{E}{kT}}}{Z_{mc}}=\frac{1}{Z_{mc}}e^{-\frac{E}{kT}} \tag{9.5.211}$$

that we can find more of the in the literature under the form:

$$\boxed{f_B(E,T)=e^{-\frac{E}{kT}}} \tag{9.5.212}$$

If we consider that in a broadly neutral gas, energy is defined only by the kinetic energy (in the case of the ideal gas!).

So with the transition to the continuum, we have:

$$Z_{mc}=\int\limits_{-\infty}^{+\infty} e^{-\frac{E}{kT}}\mathrm{d}v \tag{9.5.213}$$

Therefore, we can integrate the Boltzmann function above on all speeds and we should have:

$$P(-\infty<v<+\infty)=\int\limits_{-\infty}^{+\infty}\frac{1}{Z_{mc}}e^{-\frac{E}{kT}}\mathrm{d}v=\frac{1}{Z_{mc}}\int\limits_{-\infty}^{+\infty} e^{-\frac{\frac{1}{2}mv^2}{kT}}\mathrm{d}v=1 \tag{9.5.214}$$

With the microcanonical partition function:

$$Z_{mc}=\int\limits_{-\infty}^{+\infty} e^{-\frac{mv^2}{2kT}}\mathrm{d}v \tag{9.5.215}$$

for the normalization condition to be satisfied (and anyway it matches to the developments made earlier above!).

we recognize here an integral that is familiar to and already proven in the section Statistics during our study of the Normal distribution. Then we have:

$$Z_{mc}=\sqrt{\frac{2\pi kT}{m}} \tag{9.5.216}$$

Therefore, the probability density function can be written:

$$P(-\infty<v<+\infty)=\frac{1}{\sqrt{\frac{2\pi kT}{m}}}\int\limits_{-\infty}^{+\infty} e^{-\frac{mv^2}{2kT}}\mathrm{d}v \tag{9.5.217}$$

Now, since the speed is treated as a random variable, let us focus on the calculation of the average value of the square of the speed which traditionally is denoted as follows (the notation has no relation to the ket-bra notation as in Quantum Physics or in Functional Analysis with the dot!):

$$\langle v^2\rangle = \frac{1}{\sqrt{\dfrac{2\pi kT}{m}}}\int\limits_{-\infty}^{+\infty} v^2 e^{-\frac{mv^2}{2kT}}\,\mathrm{d}v \tag{9.5.218}$$

In statistics we would write this:

$$\mathrm{E}(v^2) = \frac{1}{\sqrt{\dfrac{2\pi kT}{m}}}\int\limits_{-\infty}^{+\infty} v^2 e^{-\frac{mv^2}{2kT}}\,\mathrm{d}v \tag{9.5.219}$$

Let us focus on:

$$\int\limits_{-\infty}^{+\infty} v^2 e^{-\frac{mv^2}{2kT}}\,\mathrm{d}v \tag{9.5.220}$$

But if we put:

$$\sigma = \sqrt{\frac{2kT}{m}} \tag{9.5.221}$$

Then we have:

$$\int\limits_{-\infty}^{+\infty} v^2 e^{-\left(\frac{v}{\sigma}\right)^2}\,\mathrm{d}v \tag{9.5.222}$$

Thus with a simple change of variable:

$$\sigma^3 \int\limits_{-\infty}^{+\infty} y^2 e^{y^2}\,\mathrm{d}y \tag{9.5.223}$$

and this is exactly the integral of the Normal centered law as proved in the section Statistics as being equal to:

$$\int\limits_{-\infty}^{+\infty} v^2 e^{-\left(\frac{v}{\sigma}\right)^2}\,\mathrm{d}v = \sigma^2\frac{\sqrt{\pi}}{2} \tag{9.5.224}$$

Therefore:

$$\begin{aligned}\mathrm{E}(v^2) &= \frac{1}{\sqrt{\dfrac{2\pi kT}{m}}}\int\limits_{-\infty}^{+\infty} v^2 e^{-\frac{mv^2}{2kT}}\,\mathrm{d}v = \frac{1}{\sqrt{\dfrac{2\pi kT}{m}}}\left(\frac{2kT}{m}\right)^{3/2}\frac{\sqrt{\pi}}{2}\\ &= \frac{1}{\sqrt{\dfrac{2kT}{m}}}\left(\frac{2kT}{m}\right)\left(\frac{2kT}{m}\right)^{1/2}\frac{1}{2} = \left(\frac{2kT}{m}\right)\frac{1}{2} = \frac{kT}{m}\end{aligned} \tag{9.5.225}$$

and finally:

$$\langle E\rangle=\frac{1}{2}m\langle v^2\rangle=\frac{1}{2}m\frac{kT}{m}=\frac{1}{2}kT \tag{9.5.226}$$

for a particle moving in one spatial dimension. We therefore fall back on the same result as the Maxwell distribution of speeds derived at page 3558 in the three multidimensional case but with a different mathematical approach.

9.5.3.4 Fermi-Dirac Distribution

The principle of indistinguishability can have very important consequences for the statistics. We distinguish two types of indistinguishable particles: bosons (like the photon) and fermions (like the electron).

Let us make two recalls:

1. The bosons correspond to particles whose representative wave function is always symmetrical, while that of fermions is antisymmetric.
2. The Pauli exclusion principle requires that two fermions can not be in the same quantum state. But the bosons can!

Their respective properties have for important consequence that the minimum energy of a set of N bosons is equal to N times the minimum energy of each boson. While for a set of fermions, the minimum energy is equal to the sum of the N lower energies.

This both types of particles cause two kinds of statistics: Fermi-Dirac statistics for fermions (that we will prove first) and the Bose-Einstein statistics for the bosons (which follows).

Figure 9.140: **Fermions, Hadrons, Leptons, Mesons, Baryons, Quarks**

So there is only one way to distribute N fermions on the accessible energy states (instead of the $N!$ for distinguishable particles). It can not be more than n_i particles in an energy level E_i there are degenerations levels g_i. So:

$$0 \leq n_i \leq g_i \tag{9.5.227}$$

The number of possible combinations for a level E_i, degenerated g_i times and having particle n_i particle is then the combinatorial $C_{n_i}^{g_i}$. The total number of configurations is therefore:

$$\Omega = \prod_i C_{n_i}^{g_i} = \prod_i \frac{g_i!}{n_i!(g_i - n_i)!} \tag{9.5.228}$$

This can be checked with the following figure:

$$\Omega_{\text{F.D.}} = \frac{g!}{n!(g-n)!} = \frac{3!}{2!(3-2)!} = 3$$

Example:
2 particles: A and B
3 states: 1, 2 and 3

$$\text{3 distinct states}\left\{\begin{array}{ccc}\hline 1 & 2 & 3\\ \hline A & A & \dots \\ A & \dots & A\\ \dots & A & A\end{array}\right\}\text{Indistinguishable } (A=B)$$

Figure 9.141: $\Omega_{\text{B.E.}}$ **states in the Fermi-Dirac distribution**

The statistics is therefore very different from the classical Maxwell-Boltzmann case. By taking the logarithm of the number of micro-states and making use of the Stirling's formula approximation as above, we get:

$$\ln(\Omega)=\sum_i\left[(g_i\ln(g_i)-g_i)-(n_i\ln(n_i)-n_i)-((g_i-n_i)\ln(g_i-n_i)-(g_i-n_i))\right] \quad (9.5.229)$$

that we can already simplify a first time:

$$\ln(\Omega)=\sum_i\left[g_i\ln(g_i)-n_i\ln(n_i)-(g_i-n_i)\ln(g_i-n_i)\right] \quad (9.5.230)$$

and differentiating this expression to find the maximum, we get:

$$\mathrm{d}\ln(\Omega)=\mathrm{d}\sum_i\left[g_i\ln(g_i)-n_i\ln(n_i)-(g_i-n_i)\ln(g_i-n_i)\right]=0 \quad (9.5.231)$$

Term by term:

1. $\mathrm{d}(g_i\ln(g_i))=0$
2. $\mathrm{d}(n_i\ln(n_i))=\mathrm{d}n_i\ln(n_i)+n_i\mathrm{d}(\ln(n_i))=\mathrm{d}n_i\ln(n_i)+n_i\dfrac{1}{n_i}\mathrm{d}n_i=\mathrm{d}n_i\ln(n_i)+\mathrm{d}n_i$
3. $\mathrm{d}((g_i-n_i)\ln(g_i-n_i))=\mathrm{d}(g_i\ln(g_i-n_i))-\mathrm{d}(n_i\ln(g_i-n_i))$
   $=g_i\left(\dfrac{1}{g_i-n_i}\right)-\mathrm{d}n_i\ln(g_i-n_i)+n_i\left(\dfrac{1}{n_i}\right)=-\mathrm{d}n_i\ln(g_i-n_i)+\dfrac{g_i+n_i}{g_i-n_i}$

But we have a conservation and symmetry:

$$\sum_{\mathrm{d}}n_i=0 \quad \text{and} \quad \sum_i\frac{g_i+n_i}{g_i-n_i}=0 \quad (9.5.232)$$

So finally:

$$-\mathrm{d}\ln(\Omega)=\sum_i\left[\ln(n_i)-\ln(g_i-n_i)\right]\mathrm{d}n_i=0 \quad (9.5.233)$$

To respect the constraints on energy and the number of particles, we still use once the Lagrange multiplier method:

$$\ln(n_i)-\ln(g_i-n_i)+\alpha+\beta E_i=0 \quad (9.5.234)$$

Which brings us to the Fermi-Dirac distribution:

$$n_i = \frac{g_i}{e^{\alpha+\beta E_i}+1} \tag{9.5.235}$$

The parameters α and β play the same role as in the Maxwell-Boltzmann distribution. Then we have:

$$\beta = \frac{1}{kT} \quad \text{and} \quad \alpha = -\frac{\mu}{kT} \tag{9.5.236}$$

Then we have:

$$\boxed{n_i = \frac{g_i}{e^{\frac{E_i-\mu}{kT}}+1}} \tag{9.5.237}$$

Thus, in quantum physics, The Fermi-Dirac statistics designate the number of indistinguishable fermions that do not interact with each other (otherwise the model is too complex) on the energy states of a system in a thermodynamic degenerated equilibrium (therefore the number of fermions occupying the given energy level!).

For macroscopic systems, the energy levels are so tight (or there are so many of the) that we can consider the energy spectrum as continuous (continuum approximation).

We will reason in this continuum context, which allows us to write by norming to the numbers of particles involved (the only one thing we ask to the function is to tell us how the N particles are distributed):

$$\boxed{f_{FD}(E,T,\mu) = \frac{n_i}{g_i} = \frac{1}{e^{\frac{E-\mu}{kT}}+1}} \tag{9.5.238}$$

(often denoted $\bar{n}_i$) or:

$$f_{FD}(\varepsilon,T,\mu) = \frac{1}{e^{\beta(\varepsilon-\mu)}+1} \tag{9.5.239}$$

for the Fermi-Dirac function with the corresponding plot further below.

This relation is very important for example in the semiconductor theory (see section Electrokinetics page 4279) which is at the base of the electronics of the 120th and 121st centuries (holocene calendar).

Numerically, we can simulate the evolution of the shape of the distribution (which is not a distribution in the mathematical sense!) in function of energy and temperature. For this, we assume for simplicity that the Boltzmann constant k is equal to 1 and the chemical potential is μ is equal to 2 (we must however notice that it is strictly speaking a function of temperature...). Thus, we can write the following small program in MATLAB® 5.0.0.473:

```
clear all;kb=1; % Boltzmann constant
mu=2; % Chemical potential
T=0.001:0.1:1; % Gradient of temperature for the script
for j=1:length(T)
   beta(j)=1/(kb*T(j));
   epsilon=0.1:0.1:4; % Energy with the step
```

```
    for i=1:length(epsilon)
       Nf(i,j)=1/(exp(beta(j)*(epsilon(i)-mu))+1); % Nb(epsilon,beta
          ) average of fermions at the level of enery epsilon
    end
    hold on
    plot(epsilon,Nf(:,j));
    pause(0)
end
```

That gives:

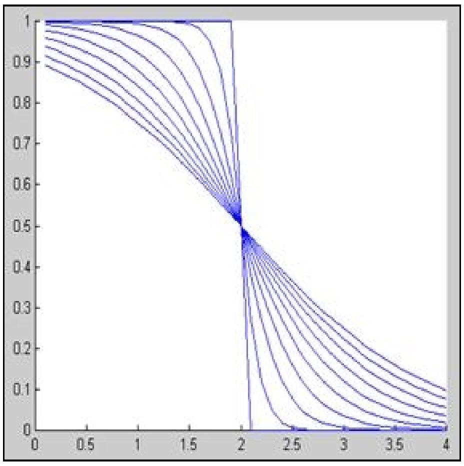

Figure 9.142: Plot of the Fermi-Dirac distribution with MATLAB® 5.0.0.473

Or for those who prefer a better quality illustration:

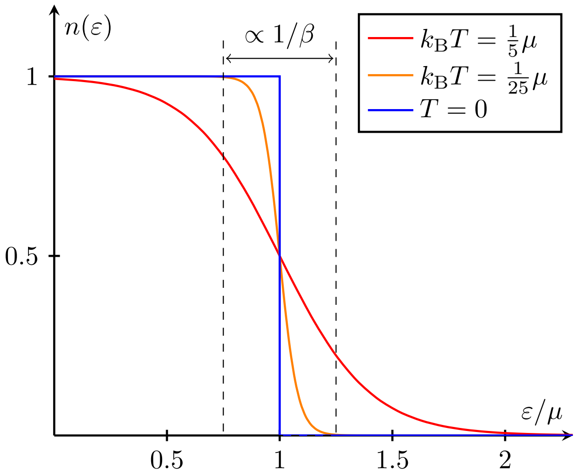

Figure 9.143: Fermi-Dirac distribution (author: Janosh Riebesell)

At absolute zero $T = 0$ [K] (see section Thermodynamics page 3620) we see that we have a step. At this temperature, the degenerate energy levels are completely occupied starting from the lowest energy level to a certain level representing the fall of step. We then say that the Fermi gas is "completely degenerated".

The Fermi-Dirac function, at absolute zero, is therefore equal to 1 if E is less than μ and 0 for higher values (the system chooses its minimum energy state where the N particles occupy the lowest N energy states).

Obviously, in the high excitation energies (or high temperatures) the probability (ratio) of occupation of a state is very low and therefore it is not important to apply the Pauli principle (the probability that two electrons want to occupy the same energy level is very low). For these reasons, this boundary system between the classical and quantum behaviour is sometimes named "classical regime" and the corresponding high temperature energy excitement is named "Fermi temperature".

The chemical potential μ is itself by definition the last occupied energy level at absolute zero energy level (the famous step!). As discussed in the section of Wave Quantum Physics (see page 4807), it is denoted by E_F (and denoted by μ in chemistry...) and we name it "Fermi level" or "Fermi energy". We then see immediately that whatever the temperature:

$$f_{FD}(E_F)=\frac{1}{e^{\frac{E_F-\mu}{kT}}+1}=\frac{1}{e^{\frac{\mu\mu}{kT}}+1}=\frac{1}{1+1}=\frac{1}{2} \tag{9.5.240}$$

So the probability of occupation by the fermions is of 0.5 at this level. The definition of the Fermi level can then be given by:

$$E_F-\mu=0 \tag{9.5.241}$$

The main application to solids of this statistic is the modelling of electron transport phenomena (electron gas): theory of metals, semiconductors, population of the energy levels and conduction properties (see section Electrokinetics page 4219).

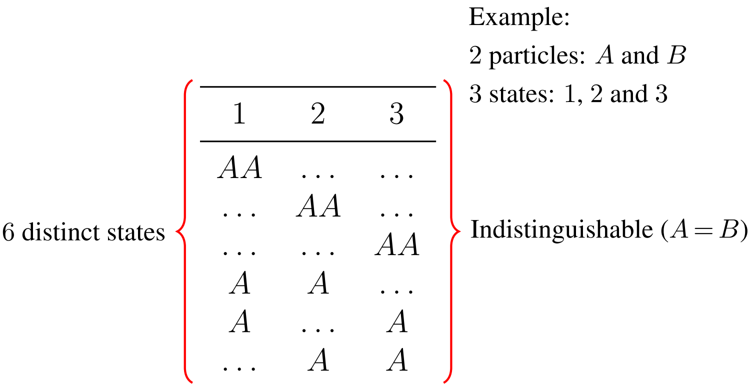
9.5.3.5 Bose-Einstein Distribution

Bosons are other quantum particles that can indifferently be placed on all energy levels. The Pauli principle does not apply to them! In this case, the number of objects to be swapped is n_i+g_i-1 (the n_i particles and the g_i-1 intervals between the levels). Because the particles are indistinguishable and interchangeable and the levels and sublevels can be permuted, we must divide by $n_i!$ but also by $(g_i-1)!$. The number of configurations on a level E_i, degenerated g_i times, containing n_i indistinguishable particles is thus equal to:

$$\Omega=\prod_i \frac{(n_i+g_i-1)!}{n_i!(g_i-1)!} \tag{9.5.242}$$

This can be verified with the following figure:

$$\Omega_{\text{B.E.}}=\frac{(n+g-1)!}{n!(g-1)!}=\frac{2+3-1}{2!(3-1)!}=6$$



Example:
2 particles: A and B
3 states: 1, 2 and 3
6 distinct states
Indistinguishable ($A=B$)

1	2	3
AA	$\ldots$	$\ldots$
$\ldots$	AA	$\ldots$
$\ldots$	$\ldots$	AA
A	A	$\ldots$
A	$\ldots$	A
$\ldots$	A	A

Figure 9.144: $\Omega_{\text{B.E.}}$ **states in the Bose-Einstein distribution**

Its logarithm with use of Stirling's formula and after simplification is given by:

$$\ln(\Omega)=\sum_i\left[(n_i+g_i-1)\ln(n_i+g_i-1)-n_i\ln(n_i)-(g_i-1)\ln(g_i-1)\right] \tag{9.5.243}$$

The maximum of $\ln(\Omega)$ corresponds to cancel $\mathrm{d}(\ln(\Omega))$, that is:

$$-\mathrm{d}(\ln(\Omega))=\sum_i\left[-\ln(n_i+g_i-1)+\ln(n_i)\right]\mathrm{d}n_i=0 \tag{9.5.244}$$

To respect the constraints on the energy and the number of particles, we use once the Lagrange multiplier method:

$$-\ln(n_i+g_i-1)+\ln(n_i)+\alpha+\beta E_i=0 \tag{9.5.245}$$

and therefore:

$$n_i=\frac{g_i}{e^{\alpha+\beta E_i}-1} \tag{9.5.246}$$

which is the Bose-Einstein statistical distribution. This distribution diverge when:

$$\alpha+\beta E_i=0 \tag{9.5.247}$$

This is the "Bose-Einstein condensate". In this state, all bosons can be found in the same state.

The parameters β and α play the same role as in the distribution Maxwell-Boltzmann and Fermi-Dirac. We have:

$$\beta=\frac{1}{kT} \quad \text{and} \quad \alpha=-\mu\frac{\mu}{kT} \tag{9.5.248}$$

The (average) number of photons is therefore given by:

$$\boxed{n_i=\frac{g_i}{e^{\frac{E_i-\mu}{kT}}-1}} \tag{9.5.249}$$

to compare with the (average) number of fermions at the same level of energy (Fermi-Dirac function):

$$n_i=\frac{g_i}{e^{\frac{E_i-\mu}{kT}}+1} \tag{9.5.250}$$

Thus, in quantum physics, Bose-Einstein statistics refers to the statistical distribution of indistinguishable bosons (all similar) and do not interact with each other (otherwise the model is too complex) on the energy states of a system at thermodynamic equilibrium.

For macroscopic systems, the energy levels are so tight (or there are so many) that we can consider the energy spectrum as continuous (approximation of the continuum).

We will reason in this context, allowing us to write by norming to the numbers of particles involved (the only one think we request is that the function tell us how the N particles are distributed):

$$\boxed{f_{BE}(E,T,\mu)=\frac{n_i}{g_i}=\frac{1}{e^{\frac{E-\mu}{kT}}-1}} \tag{9.5.251}$$

for the Bose-Einstein function (often denoted sadly also $\bar{n}_i$). It is therefore defined only for the energies higher than that of the chemical potential (if not what it is negative!).

Numerically, we can simulate the evolution of the shape of the distribution (which is not a distribution in the mathematical sense!) in function of energy and temperature. For this, we assume for simplicity that the Boltzmann constant k is equal to 1 and the chemical potential is μ is equal to 2 (we must however notice that it is strictly speaking a function of temperature...). Thus, we can write the following small program in MATLAB® 5.0.0.473:

```
clear all;kb=1; % Boltzmann constant
mu=2; % Chemical potential
T=0.001:0.1:1; % Gradient of temperature for the script
for j=1:length(T)
   beta(j)=1/(kb*T(j));
   epsilon=0.1:0.1:4; % Energy with the step
   for i=1:length(epsilon)
      Nf(i,j)=1/(exp(beta(j)*(epsilon(i)-mu))-1); % Nb(epsilon,beta
        ) average of fermions at the level of enery epsilon
   end
   hold on
   plot(epsilon,Nf(:,j));
   pause(0)
end
```

That gives:

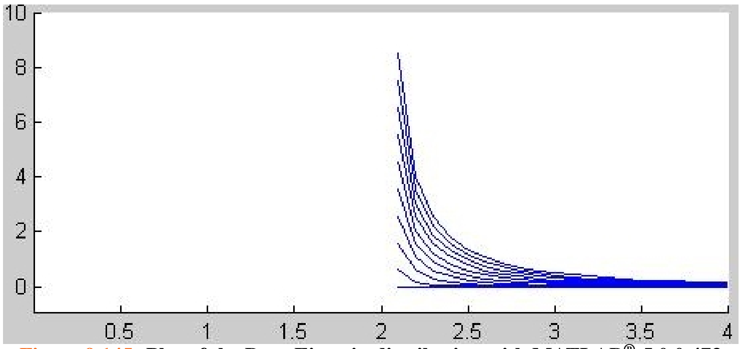


Figure 9.145: Plot of the Bose-Einstein distribution with MATLAB® 5.0.0.473

At high temperatures, when quantum effects can be neglected, the Bose-Einstein statistics, such as the Fermi-Dirac governing the fermions, tends to the Maxwell-Boltzmann statistics as show the figure below:

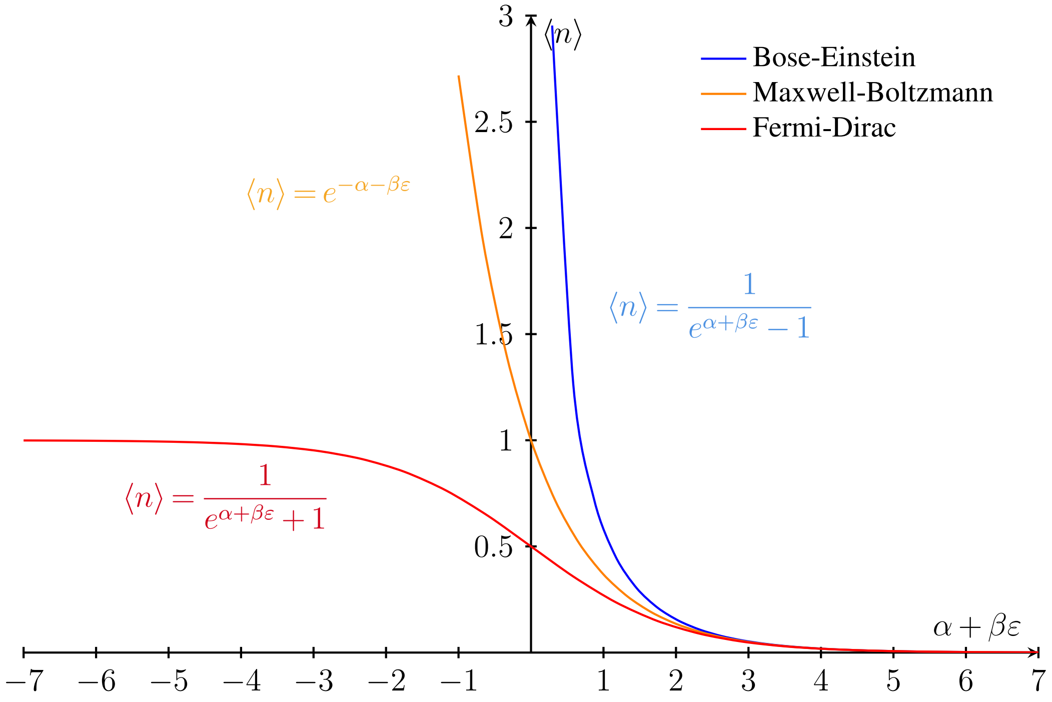

Figure 9.146: **Convergence of Maxwell-Boltzmann, Fermi-Dirac and Bose-Einstein in high temperature domain**

At low temperatures, however, the Bose-Einstein and Fermi-Dirac statistics differ from each other. Indeed, let us consider, for example, at zero temperature: in the first we expect that the level of lowest energy contains all bosons, while in the second, the lowest energy levels contain g_i fermions.

Furthermore, always at zero temperature (-273.15 [C]), the Bose-Einstein statistics obviously shows that all particles must occupy the same quantum state: the lowest energy. This phenomenon can be observed on a macroscopic scale and is name a "Bose-Einstein condensate". It is considered as a fourth state of matter with liquid, solid and plasma.

Bose-Einstein statistics is useful for the understanding of wave electromagnetic phenomena because photons are bosons (black-body radiation, interaction material/radiation). It is also very much helpful to the study of vibrational phenomena in solids (phonons follow Bose-Einstein statistics). It has also been used to explain phase transitions in helium (phenomenon at very low temperatures).

Remarks

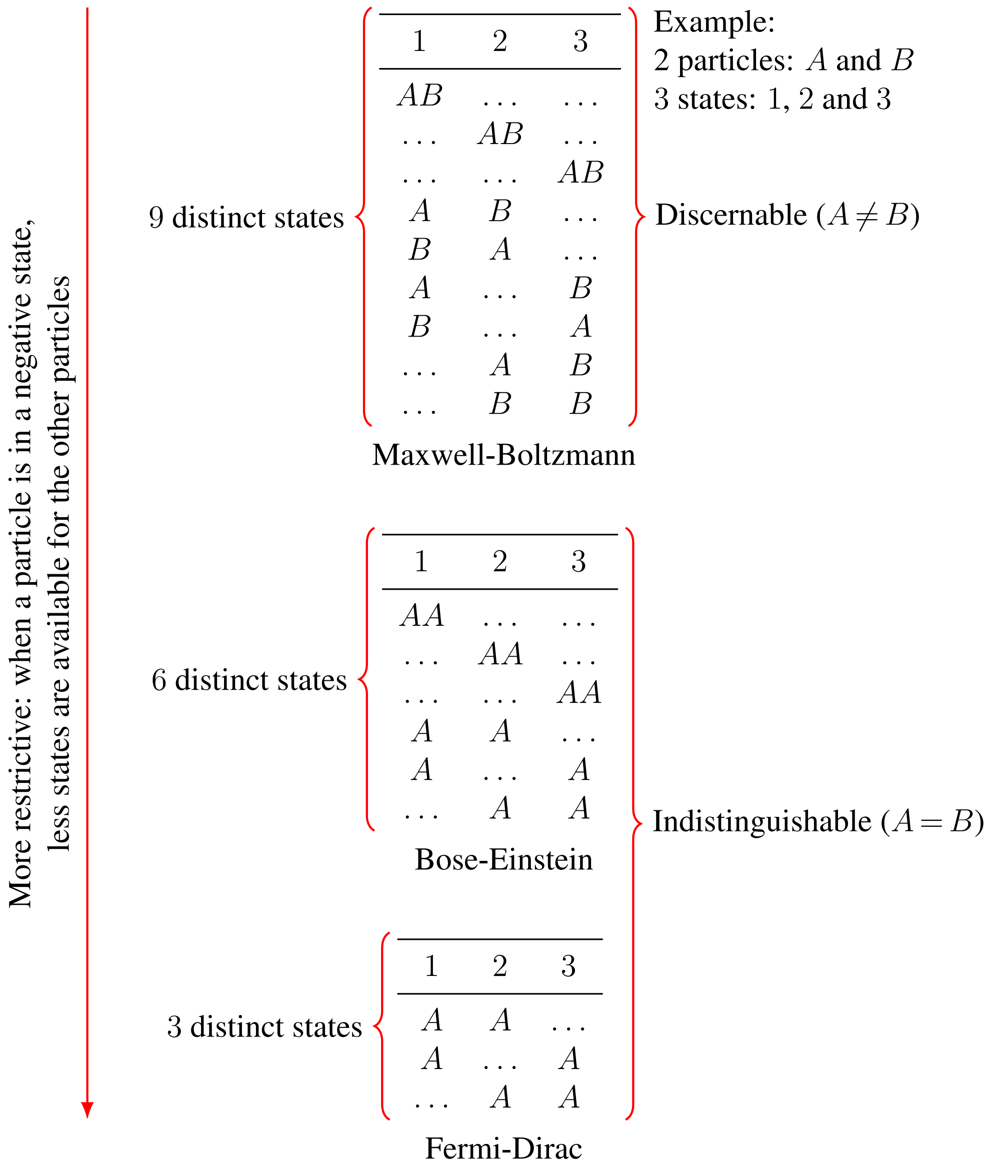
R1. The Bose-Einstein statistics was introduced by Satyendra Nath Bose in 11920 (holocene calendar) for photons and generalized to atoms by Einstein in 11924 (holocene calendar).

R2. A mathematical result named "spin-statistics theorem" connects the spin of a particle and the type of statistic that it follows. It stipulates that integer spin are bosons, while the half-integer spin are fermions. The proof of this theorem is not yet in this today.

Finally, here is a simplified summary of the things that can possibly help for a better understanding of what we see so far:

Particles	**Statistic**	**Specificity**
Bosons (photons, gluons, ...)	$n_i=\dfrac{g_i}{e^{\frac{E_i-\mu}{kT}}-1}$ Bose-Einstein-Statistic	Indistinguishable particles that do not interact. No constraint on the number of particles per state
Fermions (electrons, protons, neutrinos, ...)	$n_i=\frac{g_i}{e^{\frac{E_i-\mu}{kT}}+1}$ Fermi-Dirac Statistic	Indistinguishable particles that do not interact. No constraint on the number of particles per state
Classic	$n_i=g_ie^{\frac{\mu-E_i}{kT}}$ Maxwell-Boltzman statistics	Distinguishable particles that do not interact. No constraint on the number of particles per state

Table 9.21: **Similarities of the different quantum distributions**



More restrictive: when a particle is in a negative state, less states are available for the other particles

Example:
2 particles: A and B
3 states: 1, 2 and 3

9 distinct states

1	2	3
AB	$\dots$	$\dots$
$\dots$	AB	$\dots$
$\dots$	$\dots$	AB
A	B	$\dots$
B	A	$\dots$
A	$\dots$	B
B	$\dots$	A
$\dots$	A	B
$\dots$	B	B

Discernable ($A \neq B$)

Maxwell-Boltzmann

6 distinct states

A	A	$\dots$
A	$\dots$	A
$\dots$	A	A

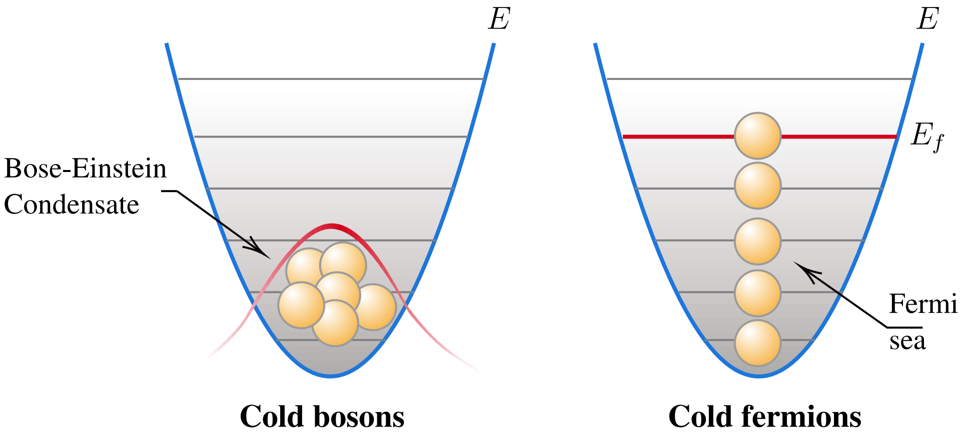
Fermi-Dirac

Figure 9.147: Summary of the Maxwell, Bose-Einstein and Fermi-Dirac distributions

Or in a more pictural way, in the absolute zero case and by representing the Fermi energy (see page 3576):



Remark

Though the theory said such Bose-Einstein state of matter should exist, it wasn't until 11995 (holocene calendar) that Eric A. Cornell and Carl E. Wieman, both of the Joint Institute for Lab Astrophysics (JILA) in Boulder, Colorado, and Wolfgang Ketterle, of the Massachusetts Institute of Technology, managed to make one, for which they got the 12001 (holocene calendar) Nobel Prize in Physics.

9.5.4 Brownian Motion (random walk)

The Brownian motion is a mathematical description of random motion of a small organic or non-organic impurity immersed in a fluid and that is not subject to any other interaction that the shocks with small molecules in the surrounding fluid. This results in a very irregular movement of the small impurity, which has been described for the first time in 11827 (holocene calendar) by Robert Brown botanist observing particle movement inside pollen grains:

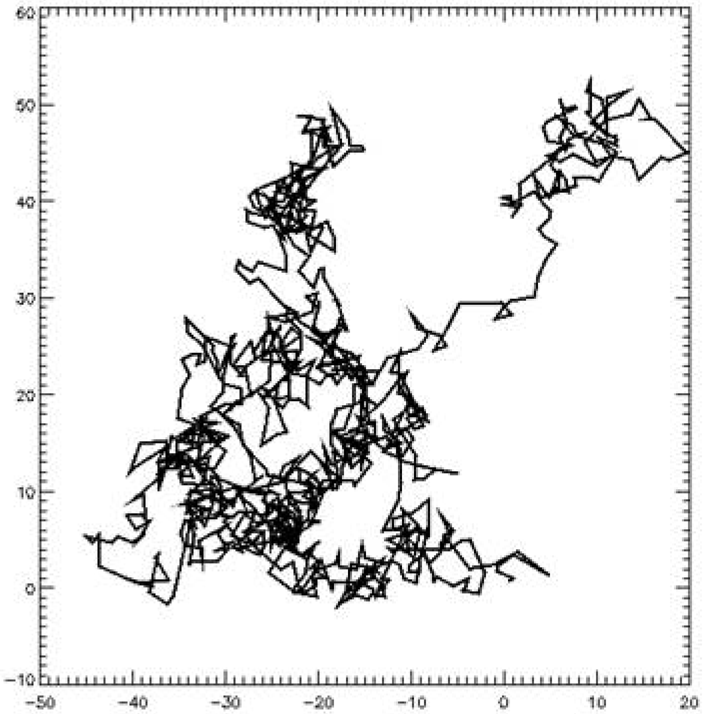


Figure 9.148: **Brownian Motion in a two-dimensional lattice**

The origin of the movement due to the molecules was not at all evident in the early 119th century (holocene calendar) as:

1. It was not yet commonly accepted that the matter was simply discontinuous and therefore made up of molecules.
2. We did not understand even assuming the molecular aspect of the matter that some molecules are capable of moving impurities several million times larger than those of the molecules of the fluid.
3. Even if we admit the molecular aspect, it was not clear that a very large amount of billions of molecules shocks do not cancel each other and the impurity is would finally not be still (we will see that this is due to that the material is not continuous).

The mathematical treatment of the problem using molecular and statistical point of view of the matter was a claim for scientific proponents of atomic aspect of the matter and opened once again the door to the new domain of Statistical Mechanics already slightly used at that time by James Clerk Maxwell in the context of gas studies.

The reader must keep in mind that Brownian motion is one of the most important building block for continuous-time asset pricing models (see section Economy page 7689). It has a long history in the modelling of random events in science.

Before we go in the mathematical physics aspect of the Brownian motion let us see an interesting numerical example with Maple™ 4.00b:

✍**Example:**

First our aim is to simulate a path of a particle with Brownian motion:

```
>restart;
with(linalg):
with(plots):
```

First, we create an array to save the variables in, and we define the initial point of the path as the origin of the grid:

```
>a:=array(1..2,1..5000);
a[1,1]:=0;
a[2,1]:=0;
```

To plot the path, we will have to create an array with points as entries:

```
A:=array(1..5000);
```

So here comes the interesting part:

The idea of Brownian Motion is, that the particle moves randomly to a neighboured position on the grid. To simulate this, we create a random variable R, which can be $\{1, 2, 3, 4\}$. In the for-loop following, we set the next point in the path according to the value of R, where `a[i-1]` is the last position, and `a[i]` the actual.

```
>X:=rand(1..4);
for i from 2 to 5000 do
R:=X();
if (R=1) then a[1,i]:=a[1,i-1]+1:  a[2,i]:=a[2,i-1]
elif (R=2) then a[2,i]:=a[2,i-1]+1:  a[1,i]:=a[1,i-1]
elif (R=3) then a[1,i]:=a[1,i-1]-1:  a[2,i]:=a[2,i-1]
elif (R=4) then a[2,i]:=a[2,i-1]-1:  a[1,i]:=a[1,i-1]
fi:
od:
```

Recall: `A[i]` is the array where the points are saved in!

```
for i from 1 to 5000 do
A[i]:=[a[1,i], a[2,i]]:
od:
```

So we finally can plot the path:

```
>pathpl:=plot(A):
pts1:=plot([A[1],A[5000]], style=POINT, color=blue):
```

```
>display(pathpl, pts1);
```

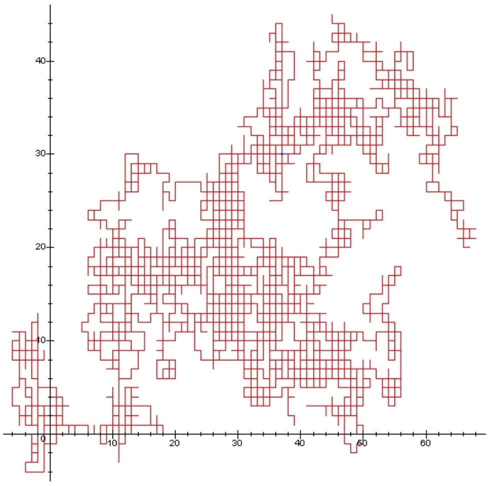

Figure 9.149: **Brownian motion plot with Maple™ 4.00b**

After creating the path, the final points of paths with Brownian motion should be distributed randomly. Let's do the simulation!

We restart to save memory:

```
>restart;
```

In order to get the final points of paths with Brownian motion, we have to do a for-loop over our created Brownian paths `b[j]` and save the final point in an array we shall call `B[j]` (the array `B1[j]`, `Bx[j]` and `By[j]` will be discussed later):

```
>B:=array(1..5000):
B1:=array(1..5000):
Bx:=array(1..5000):
By:=array(1..5000):
```

We don't have to save the path, this time, so we will just create an array with two entries to save the path in, and we will overwrite the last point with each step:

```
>b:=array(1..2);
```

But we have to reset the actual point to the origin each time we do the `i`-loop for the path (the `j`-loop is for saving the final points):

Remark

For calculations purposes, the paths have only a length of $1,000$ steps in this loop Thermodynamics...

```
>mov:=rand(1..4);
```

```
for j from 1 to 5000 do
b:=[0,0]:
for i from 2 to 1000 do
X:=mov();
if (X=1) then b[1]:=b[1]+1:
elif (X=2) then b[2]:=b[2]+1:
elif (X=3) then b[1]:=b[1]-1:
elif (X=4) then b[2]:=b[2]-1:
fi:
if (i=999) then B1[j]:=b fi:
od:
B[j]:=b:
Bx[j]:=b[1]:
By[j]:=b[2]:
od:
```

So now we can plot these final points:

```
>plot(B, style=POINT);
```

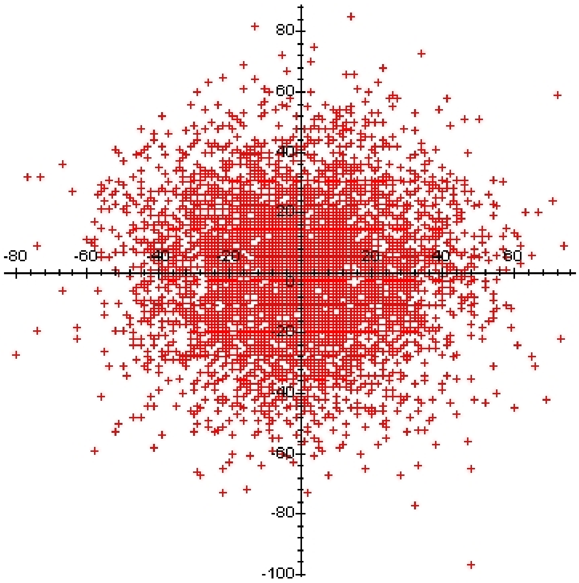

Figure 9.150: **Brownian Motion final (x, y) positions plot with Maple™ 4.00b**

So now we should check, whether the prediction, that the points are really randomly scattered, is really true: Therefore, it is useful to plot the number of paths ending at a certain x-value and the y-values, respectively, to the values themselves - we should see a Gaussian distribution. To do that, we had to create the arrays `Bx[j]` and `By[j]`, so we can now build up a number array for both the axis' and then plot it's distributions:

```
>Nx:=array(1..200):
Ny:=array(1..200):
for j from 1 to 200 do
Nx[j]:=0:
Ny[j]:=0:
od:
```

To count the number of paths ending at a certain point, we have to make a loop over the path and raise the corresponding entry:

```
>Nx:=array(1..200):
Ny:=array(1..200):
for j from 1 to 200 do
Nx[j]:=0:
Ny[j]:=0:
od:
```

and:

```
>pNx:=array(1..200):
pNy:=array(1..200):
for j from 1 to 200 do
pNx[j]:=[j, Nx[j]]:
pNy[j]:=[j, Ny[j]]:
od:
```

which gives visually:

```
>plot(pNx, style=POINT, color=red);
plot(pNy, style=POINT, color=green);
```

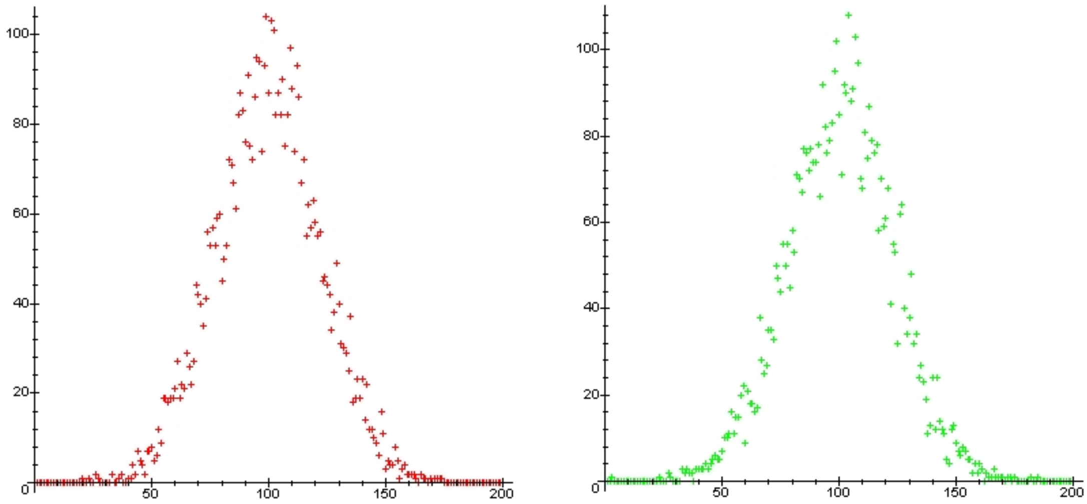

Figure 9.151: **Brownian Motion final x and y positions distributions plot with Maple™ 4.00b**

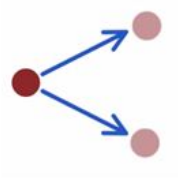
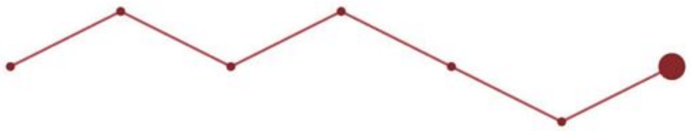
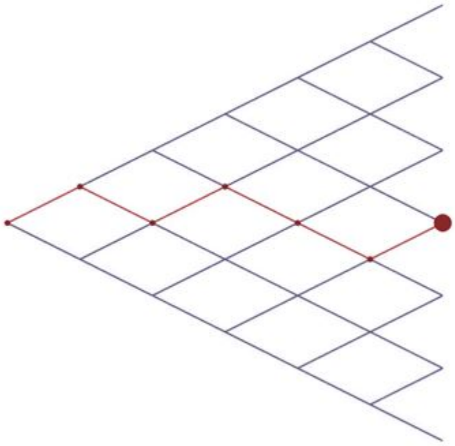
There is also a very well known random walk named "binomial tree" (in finance and radiation) that is given the rule that at each trial, a particle can only go up (U) or down (D):



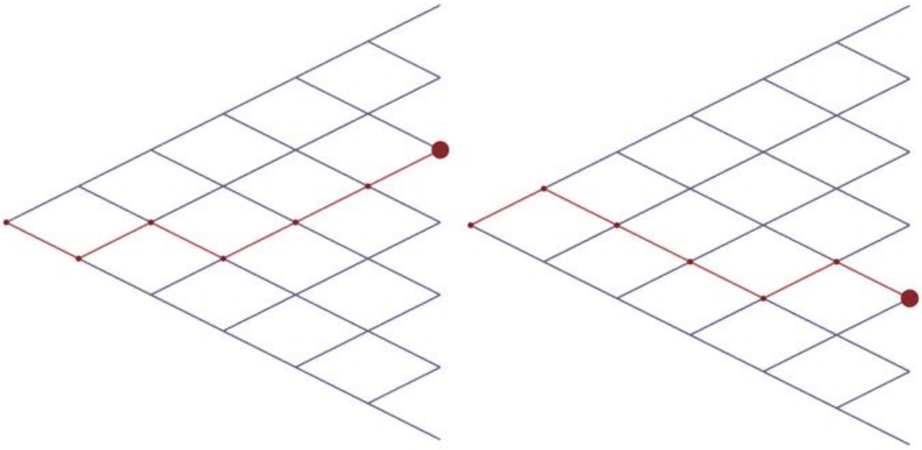
Then a UDUDDU walk will give:



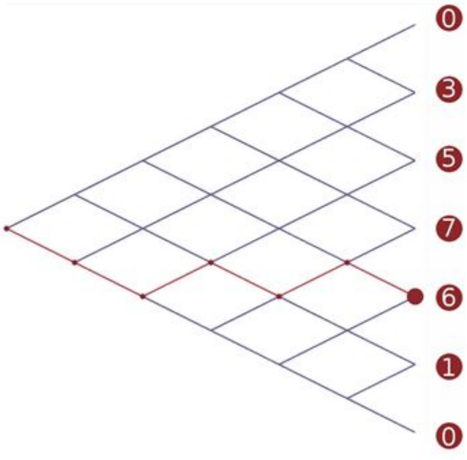
Represented on a grid of all possibilities this gives:



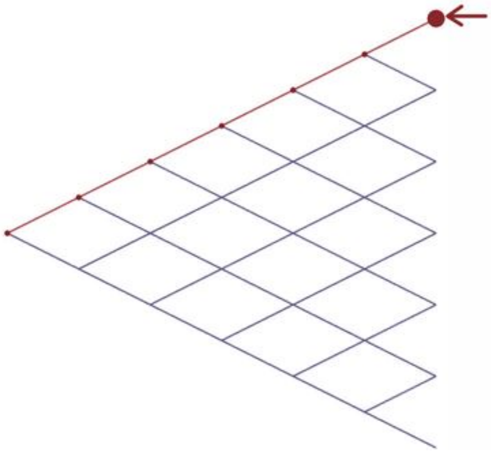
Or with other different paths (DUDUUU and UDDDUD):



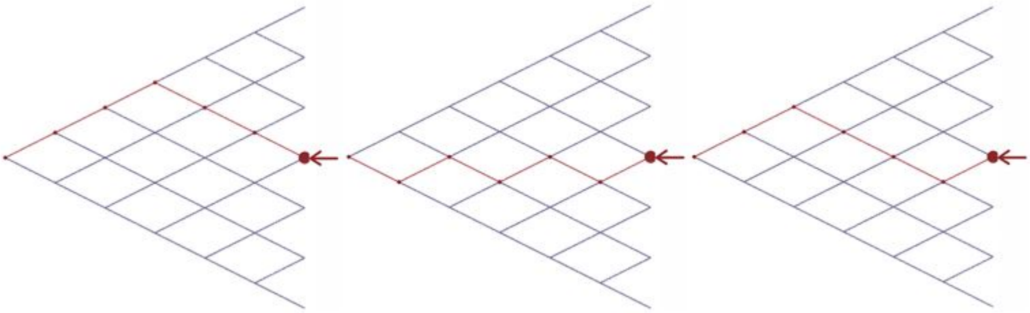
If we run multiple paths on the same grid we notice that there are more paths converging near the center rather than in the extremities:



The explanation is obvious! There is only on way (combination UUUUUU or DDDDDD) to arrive at the extremities:

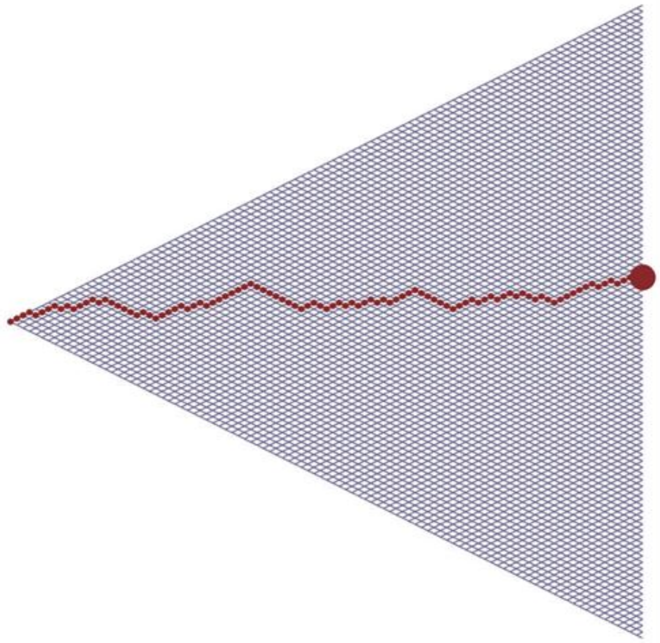


But there are multiple ways to arrive at the center:

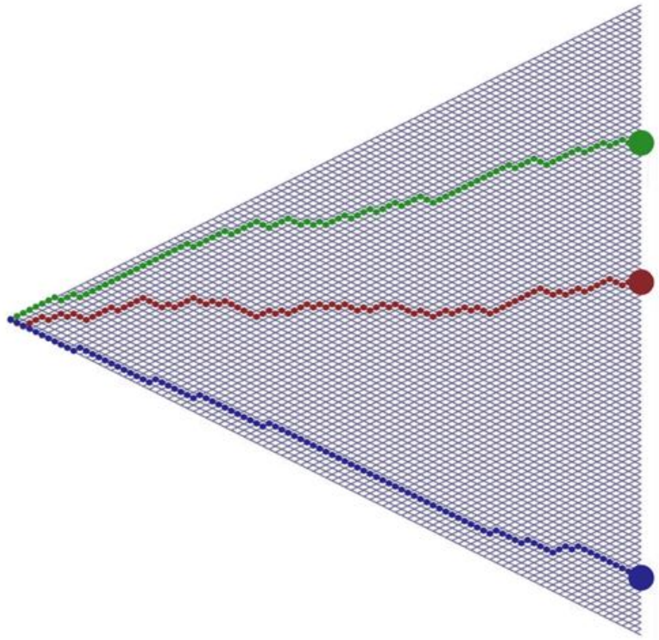


There are above 20 different paths to get to the middle in 6 trials. So there is 20 times more chance that the particle arrives in the middle than on one of the points of the extremities.

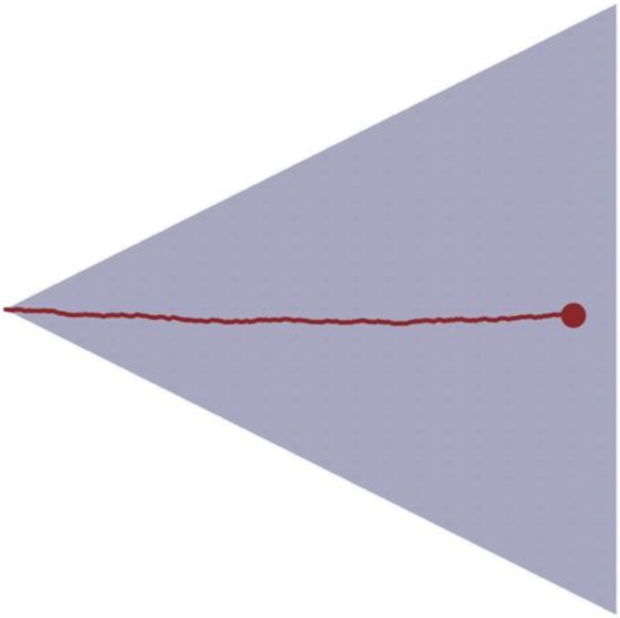
This concentration towards the center will be accentuated if we increase the size of the tree (the user can reproduce this example using the code given in the `R` companion book):



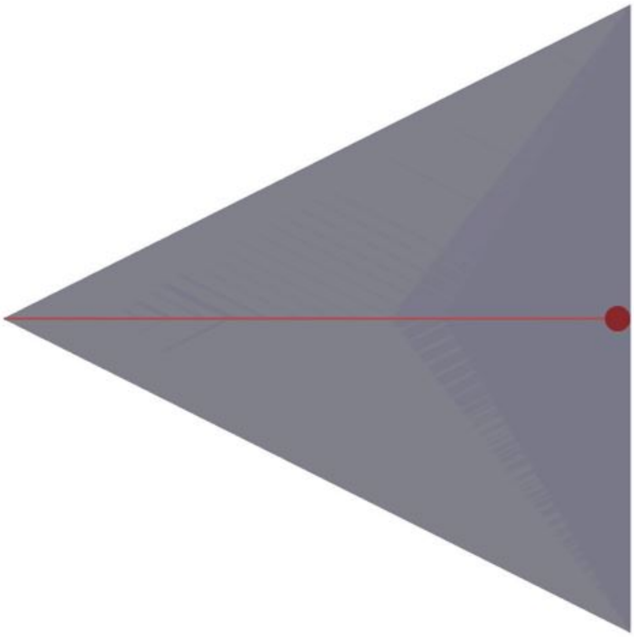
Of course the green or blue path are not completely unlikely:



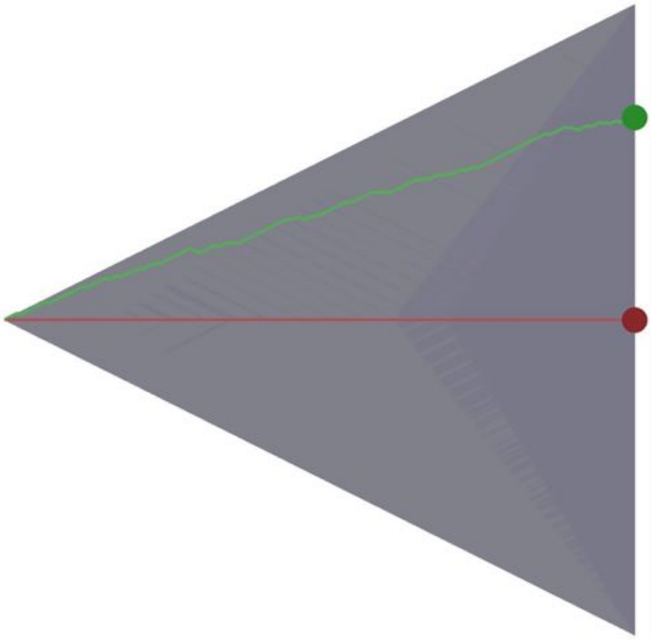
With $1,000$ steps the most likely trajectories look almost straight:



With $1,000,000$ million steps, the question does not arise anymore:



With $1,000,000$ million steps the green path below is highly unprobable (but not impossible!):



But we can also do the same simulation with a grid centered on a disc with particles starting from the edge of the disc and towards the outside. Therefore, we observe that the particles have a high probability of travelling radially from the center (typically the photons emitted on the surface of the Sun)! If this were not the case it could be statistically that for a given duration, with a given probability, no solar radiation would reach us (or on the contrary ALL the radiations emitted from the Sun may go towards us). But this does not happen precisely because of this type of probabilistic behaviour. This guarantees with a near certainty in probability that the Sun radiates homogeneously throughout the space. And we must keep in mind that all the equations of physics involving particle systems are statistical phenomena that converge in law towards a given behaviour.

So physics laws of particles systems are not absolutely true but statistically accurate!

As always there are several mathematical models and as it is the tradition in this textbook we chose the easiest one ... it is not that of Albert Einstein but of Paul Langevin (conducted two years after for a simplification purpose).

The starting point is the theorem of equipartition of kinetic energy (see section Continuum Mechanics page 3902):

$$E_c = N\frac{1}{2}mv^2 = \frac{3}{2}\frac{R}{N_{\text{A}}}NT \tag{9.5.252}$$

That is to say for only one particle:

$$E_c = \frac{1}{2}mv^2 = \frac{3}{2}\frac{RT}{N_{\text{A}}} \tag{9.5.253}$$

with for recall v that is the average speed! If we simplify the analysis to a single possible axis of translation the relation becomes (we specify now that it is the average speed in order not make a confusion later with another quantity):

$$\bar{E}_c = \frac{1}{2}m\bar{v}_x^2 = \frac{1}{2}\frac{RT}{N_{\text{A}}} \tag{9.5.254}$$

By writing this we stipulate that a particle in suspension in a fluid in thermal equilibrium has, in the x direction, for example, an average kinetic energy equal to that of a gas molecule of any kind in a given direction, at the same temperature. So this is again a strong identity between dilute solutions and ideal gases.

A particle like the one we are considering, large compared to the molecules of the liquid and moving at speed v with respect to the latter undergoes as we have proved in the section of Continuum Mechanics (Stokes law) a resistance given by:

$$F_{st.}=-6\pi\mu Rv=-\xi v \tag{9.5.255}$$

where ξ will be named "friction coefficient" (corresponding therefore to the viscosity) and where R is the radius of the sphere.

Now we write according to the dynamics equation of Newton (we no longer specifies that the speed is along x in the notation below):

$$m\frac{\mathrm{d}v}{\mathrm{d}t}=m\frac{\mathrm{d}^2x}{\mathrm{d}t^2}=-6\pi\mu Rv+F_{\text{rand}} \tag{9.5.256}$$

The supplementary rand force F_{rand} introduced initially by Langevin, is random (stochastic). We know a priori little of it, except that it seems a priori either positive or negative, and that his magnitude is such that it maintains the agitation of the particle, which without it would end moving by stopping under the effect of viscous resistance.

The above relation multiplied by x, can be also written:

$$mx\frac{\mathrm{d}v}{\mathrm{d}t}=-\xi xv+xF_{\text{rand}} \tag{9.5.257}$$

$$\boxed{mx\frac{\mathrm{d}v}{\mathrm{d}t}=-\xi xv+xF_{\text{rand}}} \tag{9.5.258}$$

This equation is named "Langevin equation" or "stochastic Langevin equation".

But, let us recall that (see section Differential and Integral Calculus page 1475):

$$\mathrm{d}(xv)=x\mathrm{d}v+v\mathrm{d}x\Leftrightarrow\frac{\mathrm{d}(xv)}{\mathrm{d}t}=x\frac{\mathrm{d}v}{\mathrm{d}t}+v\frac{\mathrm{d}x}{\mathrm{d}t} \tag{9.5.259}$$

hence:

$$x\frac{\mathrm{d}v}{\mathrm{d}t}=\frac{\mathrm{d}(xv)}{\mathrm{d}t}-v\frac{\mathrm{d}x}{\mathrm{d}t}=\frac{\mathrm{d}(xv)}{\mathrm{d}t}-v^2=\frac{\mathrm{d}\left(x\frac{\mathrm{d}x}{\mathrm{d}t}\right)}{\mathrm{d}t}-v^2=\frac{\mathrm{d}\left(\frac{1}{2}\frac{\mathrm{d}x^2}{\mathrm{d}t}\right)}{\mathrm{d}t}-v^2=\frac{1}{2}\frac{\mathrm{d}^2x^2}{\mathrm{d}t^2}-v^2 \tag{9.5.260}$$

By establishing the latte relation, we have also just proved that:

$$xv=\frac{1}{2}\frac{\mathrm{d}^2}{\mathrm{d}t} \tag{9.5.261}$$

We can then write:

$$\frac{1}{2}m\frac{\mathrm{d}^2x^2}{\mathrm{d}t^2}-mv^2=-\xi xv+xF_{\text{rand}} \tag{9.5.262}$$

and also:

$$\frac{1}{2}m\frac{\mathrm{d}^2x^2}{\mathrm{d}t^2}-mv^2=-\xi\frac{1}{2}\frac{\mathrm{d}x^2}{\mathrm{d}t}+xF_{\text{rand}} \tag{9.5.263}$$

If we take the average (we change the notation of the average using the over bar by angle brackets that seem more adapted to us:

$$\frac{1}{2}m\frac{\mathrm{d}^2\langle x^2\rangle}{\mathrm{d}t^2}-m\langle v^2\rangle=-\xi\frac{1}{2}\frac{\mathrm{d}\langle x^2\rangle}{\mathrm{d}t}+\langle xF_{\text{rand}}\rangle \tag{9.5.264}$$

We put now that:

$$\langle xF_{\text{rand}}\rangle=0 \tag{9.5.265}$$

in other words we can see that as the average work of the random force.

Therefore it remains:

$$\frac{1}{2}m\frac{\mathrm{d}^2\langle x^2\rangle}{\mathrm{d}t^2}-m\langle v^2\rangle=-\xi\frac{1}{2}\frac{\mathrm{d}\langle x^2\rangle}{\mathrm{d}t} \tag{9.5.266}$$

Let us put:

$$u=\frac{1}{2}\frac{\mathrm{d}\langle x^2\rangle}{\mathrm{d}t} \tag{9.5.267}$$

Then we have:

$$m\frac{\mathrm{d}u}{\mathrm{d}t}-m\langle v^2\rangle=-\xi u \tag{9.5.268}$$

And as:

$$m\langle v^2\rangle=\frac{RT}{N_{\text{A}}} \tag{9.5.269}$$

Therefore:

$$m\frac{\mathrm{d}u}{\mathrm{d}t}-\frac{RT}{N_{\text{A}}}=-\xi u \tag{9.5.270}$$

Or written differently:

$$m\frac{\mathrm{d}u}{\mathrm{d}t}+\xi u=\frac{RT}{N_{\text{A}}} \tag{9.5.271}$$

This is a differential equation with constant coefficient or order 1. We have proved in the section of Differential and Integral Calculus that the homogeneous solution was:

$$u_h=Ce^{-\frac{\xi}{m}t} \tag{9.5.272}$$

where the constant C is not important for now as we will see that it will vanish anyway in the developments that will follow. The special solution can be determined by the constraint at time zero:

$$m\frac{\mathrm{d}\left(Ce^{-\xi}mt+u_p\right)}{\mathrm{d}t}+\xi\left(C^{-\frac{\xi}{m}t}+u_p\right)=\frac{RT}{N_\text{A}} \tag{9.5.273}$$

That is after derivation and have put $t=0$ gives:

$$m\frac{\mathrm{d}u_p}{\mathrm{d}t}+\xi u_p=\frac{RT}{N_\text{A}} \tag{9.5.274}$$

A simple trivial solution is then:

$$u_p=c^{te}=\frac{RT}{\xi N_\text{A}} \tag{9.5.275}$$

Then we have:

$$u=\frac{1}{2}\frac{\mathrm{d}\langle x^2\rangle}{\mathrm{d}t}=u_h+u_p=\frac{RT}{\xi N_\text{A}}+Ce^{-\frac{\xi}{m}t} \tag{9.5.276}$$

But after a short time the term in the exponential becomes almost zero. So we have in the steady state:

$$\frac{1}{2}\frac{\mathrm{d}\langle x^2\rangle}{\mathrm{d}t}=\frac{RT}{\xi N_\text{A}} \tag{9.5.277}$$

Therefore:

$$\boxed{\langle x^2\rangle=\frac{2RT}{\xi N_\text{A}}t=2Dt} \tag{9.5.278}$$

where D is the "diffusion coefficient" (as in Thermodynamics). We notice therefore that the average position of the travelled distance x is by extensions proportional to the square root of time:

$$x\propto\sqrt{t} \tag{9.5.279}$$

Albert Einstein had applied a numerical example with particles in suspension of a thousandth of a millimetre in water at 290 [K] and thus found a average moving path distance of six thousandths of a millimetre in a minute.

The relation (where it should not be any confusion between the radius R of the particle in suspensions in the denominator with the R of ideal gas constant in the numerator):

$$\boxed{D=\frac{RT}{\xi N_\text{A}}=\frac{RT}{N_\text{A}}\frac{1}{6\pi\mu R}} \tag{9.5.280}$$

is named "Stokes-Einstein relation" or sometimes "Sutherland-Einstein relation" (as William Sutherland discovered it in Australia almost at the same time when Einstein wrote this same relation in his thesis) and that we can also found frequently in the literature in the following form (where k if for recall the Boltzmann constant):

$$D=\frac{RT}{\xi N_\text{A}}=\frac{kT}{\xi} \tag{9.5.281}$$

Albert Einstein had thus found a relation that offered the possibility of calculating the radius R of atoms with a thermometer, a microscope and a stopwatch for only instruments. The physicist Jean Perrin won the Nobel Prize for experimental verification of this result.

The reader will notice that if we do the same developments as before but by dividing the left and right differential equation:

$$m\frac{\mathrm{d}u_p}{\mathrm{d}t}+\xi u_p=\frac{RT}{N_\mathrm{A}} \tag{9.5.282}$$

by m we would have get for result (rightly considered as more general):

$$\boxed{D=\frac{kT}{\xi m}} \tag{9.5.283}$$

The Langevin method gives the same result as the first model proposed by Albert Einstein two years earlier and the second model two years later.

One may wonder in what the Sutherland-Einstein relation proves the existence of molecules??? In other words, what would be the limit of the diffusion coefficient D if Nature was continuous, that is to say, if Avogadro's number N_A was infinite!

We obviously see that then D would vanish (asymptotically equal to 0), and that the Brownian diffusion movement would then also simply vanish in this limit. In other words, the Brownian motion would cease immediately if Nature was continuous! This is a remarkable proven result for the discrete aspect of Nature and some given scale level!

9.6. Thermodynamics

THERMODYNAMICS is the part of physics (and chemistry) that deals with the relations that permits to formally determine the exchanges (variations) of energy in the form of mechanical work and heat or radiation through the study of the transformations of the 4 basics states of matter (solid, liquid, gases and plasmas but mainly ideal gas at high-school) under the basis of simplifying assumptions between a system (isolated, open or closed) and its external environment.

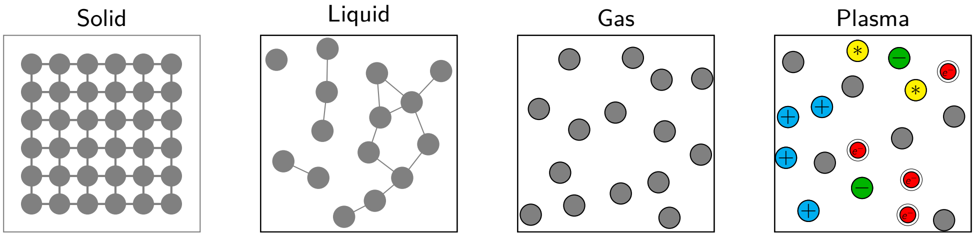

Figure 9.152: **Illustration of the naive states of matter**

Thermodynamics defines macroscopic variables, such as internal energy, entropy, and pressure, that partly describe a body of matter or radiation. It states that the behaviour of those variables is subject to general constraints, that are common to all materials, beyond the peculiar properties of particular materials. These general constraints are expressed in the four laws of thermodynamics.

The main objectives of thermodynamics are:

1. With a minimum of variables to determine the state and energy exchanges of a system (closed or open) under predefined constraints and often considered ideal ... (there are roughly a 5% difference between the theoretical values and those measured) and between states of equilibrium and thus without the time variable.
2. To find the "state variables" (defining the state of the system studied at thermodynamic equilibrium) such that these different information can be obtained in the ideal case by knowing only the final and initial state of a system.
3. To find workarounds to always to bring the equations to a form highlighting variables (variations) easily measurable in practice.

We will see later that almost any system can be energetically described by:

1. Its volume, mass, pressure, temperature, number of items, ...

2. Its potential energy, kinetic energy, chemical potential, ...
3. Its physical properties such as the ability to absorb heat, irradiating, ...

Caution!! Although the predictive power of thermodynamics equations is exciting to put into practice, this theory is ultimately... unfortunately (and inevitably)... a jungle of equations because of the number of possible combinations of some parameters that we can choose at leisure as fixed or variable in practice. So we encourage the reader to practice mentally in every day life thermodynamics because as we say... there is nothing better than learning by doing!

Remarks

R1. In our point of view it is very difficult to introduce Thermodynamics in a purely linear way unlike other areas of physics. The outline of this section is therefore currently a real mix of concepts that are sometimes defined previously and others that are only defined much later in the text. The reader will therefore understand that this section in its present form requires a major restructuring and addition of a lot of illustrations to be mature and this will be done in a more or less future time ...

R2. This section contains only few classical real and school applications examples because the assumptions needed to apply the theoretical thermodynamic equations are so restrictive and even sometimes absurd that the example loses all its interest (and yet the majority of examples / exercises in schools engineers and universities are of this type in our point of view...).

R3. Many authors make "proofs" (in their own words) only with figures or schema in the field Thermodynamics. We wanted to absolutely avoid this knowing that a schema or figure is in no way a proof but only an illustration of an idea and that it becomes useless afterwards in some application fields such as Quantum Thermodynamics...

It may help some students (especially students that are more "business oriented") to work and study with Thermodynamics by doing the following analogies: the energy E is the amount of money in market, the volume V corresponds to a market size, the pressure P corresponds the concurrency density, the temperature T corresponds to the cash-flow volatility, the number of atoms or molecules n correspond to the number of individuals, and so on... (hope it may help!).

9.6.1 Thermodynamic Variables

In thermodynamics, there are several major concepts very useful depending on the type of studied system maintained or left in free evolution and the measurement methods available.

We wish here to give the most important definitions, and if possible we will prove their origin knowing that it is very difficult to have a purely linear presentation of the subject of Thermodynamics (as already mentioned!).

Definitions (#9.6.457):

D1. A "system" is a body or a group of bodies undergoing or not evolutions and that constitutes a well-defined and delimited set in space and surrounded by the external environment (or isolated from it). The set system/external environment is named a "Universe".

D2. The "work", denoted W, is the energy associated with the value or to the change of dynamics of a system through the application of various mechanical or electrical forces (hence the choice of the term "work" ...).

D3. The "heat" or "heat energy", denoted Q, is the energy associated with the value or change of the dynamics of a system due to the average agitation of the molecules, atoms or particles (average kinetic energy).

D4. The "total energy" of a system, denoted E_{tot}, is the sum of all the energies that specify the system with respect to its center of mass (moment of inertia, mass, internal kinetic energy, etc.) and also (!) relative to an external reference (kinetic energy, potential energy, incoming radiation, etc.).

D5. The "external energy" which is related to the position of the system like the kinetic energy or potential energy (gravitational / electrostatic).

D6. The "internal energy" of a system, denoted U, is the sum of all types of internal energies that only distinguish it from its center of mass such as the work W exchanged with the outside, the heat Q exchanged (internal average kinetic energy), the mass energy (relativistic, nuclear), the moment of inertia, etc.

Many high-school books show that at this point in our study of physics, we have typically as total energy of a body and therefore considered as internal energy:

$$E_{\text{tot}} = \underbrace{\underbrace{\underbrace{\frac{1}{2}mv^2}_{\text{kinetic energy}} + \underbrace{\frac{1}{2}J\omega^2}_{\text{rotation energy}}}_{\text{total kinetic energy}} + \underbrace{mgh}_{\text{gravitational energy}} + \underbrace{\frac{1}{2}kx^2}_{\text{elastic potential energy}}}_{\text{total mechanical energy}} + \underbrace{m_0c^2}_{\text{mass energy}} + \ldots \qquad (9.6.1)$$

But when talking about ideal gases, their are no chemical interaction, no complex phase structure (because of no interaction), (usually) no significant potential energy. And the kinetic energy of each of the atoms is just the same as thermal energy or temperature. So in this special case, the internal energy equals "thermal energy" - but only for an ideal gas!

D7. The "exchanged energy" which are therefore the energies that are exchanged with the outside. The most common are the mechanical/electrical work W and heat Q defined above.

D8. The "entropy", denoted S, quantifies the quality and direction of change of the energy of a system. We will prove later that the entropy of an isolated system can only increase.

D9. The "enthalpy", denoted H, is the quantity of heat received by a system that operates at constant pressure (isobaric). In chemistry this concept is very useful as a chemical transformation (or physical) part of the injected energy will just served to push the ambient atmosphere during the volume change in the transformation. Thus, the enthalpy adds to the internal energy U a corrective term taking into account the energy stored/lost by the surrounding pressure that compresses the system (if it is compressible...).

D10. The "free energy" or "Helmholtz energy", denoted F, characterizes the internal energy fraction used in the form of work. It is simply the difference between the internal energy and the dissipated heat energy because of entropy at a given temperature.

D11. The "free energy" or "Gibbs free energy", denoted G, characterizes the enthalpy fraction available as work. It is simply the difference between the enthalpy and the dissipated heat energy because of the entropy at a given temperature.

The reader must keep in mind that if not explicitly indicated otherwise, thermodynamic variables are averages of all possible values of the system (otherwise we should deal all the time with statistical distribution and this would be a pain in the ass to do so...).

For summary, and in order of appearance and importance we have the following types of energy:

Symbol	Description
W	Work
Q	Heat
P	Pressure
T	Absolute temperature
V	Volume
E_{tot}	Total Energy
U	Internal Energy
S	Entropy
H	Enthalpy
F	Free energy
G	Free enthalpy

Table 9.22: **Most famous type of energy in thermodynamics**

Let us indicate that we will not return back on the concept of temperature T that is, as we have already seen in the section of Continuum Mechanics (virial theorem page 3897) and Statistical Mechanics (black-body radiation), a parameter that can advantageously link the average movement of different bodies with their average kinetic energy (meaning their "excitement" or "disorder") or respectively the radiation of certain bodies with their emission energy. But let us still recall the origin of the zero Kelvin, because this is a redundant question on the web:

We have proved in the section of Continuum Mechanics that at constant pressure P ("isobaric" system), the volume of a fixed amount of ideal gas is proportional to the absolute temperature. This is the "Gay-Lussac's law" (in the case of perfect gases ...!):

$$V = c^{te}T \tag{9.6.2}$$

and we have then mentioned that the experimental measurements then give a straight right, which extrapolated (somewhat abruptly ...) in negative values of temperature in Celsius gives zero volume for an ideal gas (neglecting quantum aspects to this border ...) at a temperature systematically of -273.15 [°C]:

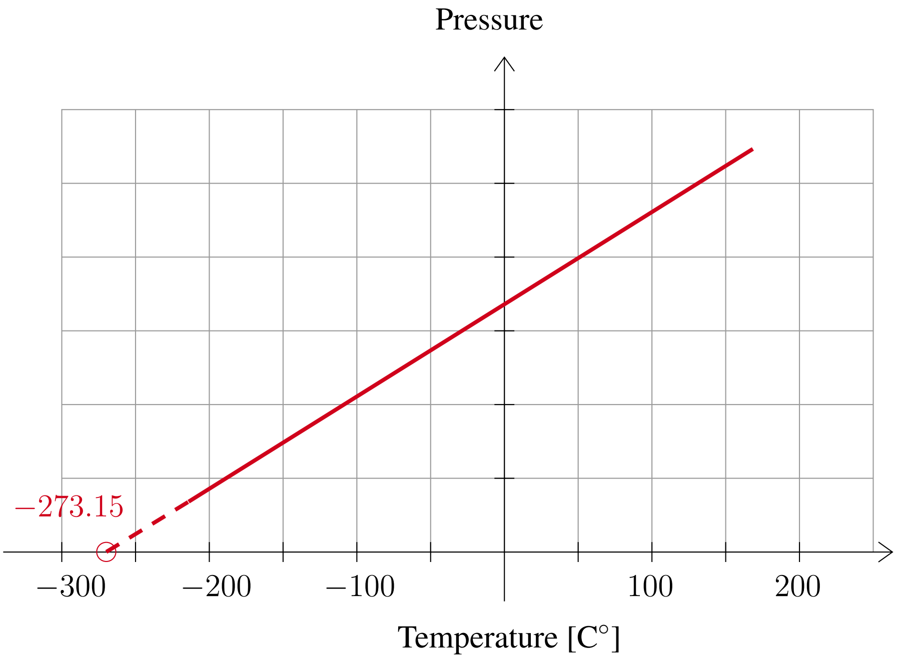

Figure 9.153: Representation of the Gay-Lussac law with pressure

hence the comfortable choice to put the 0 [K] at this value and redefine a new temperature scale!

Moreover, a difficulty is to talk about temperature change, as for example when we study the sensitivity of water to move from solid to liquid phase. We indeed observe experimentally that under ideal laboratory conditions when we move from -0.1 [°C] to $+0.1$ [°C] it is enough to observe the passage of qualitative change of water from liquid to solid state. Speak then of sensibility of $\%$ of temperature is difficult with the traditional scale in this case. But if we talk in absolute scale then this corresponds to a temperature changes from 273.05 to 273.25 [K], that is to say a phase transition sensitivity to water of 0.1% in temperature around its melting point.

9.6.2 Thermodynamics Systems

Most of time a thermodynamic system is the set of bodies located inside an imaginary closed surface defined by a "border" and often considered extensible without loss of energy.

The border can also under indication of its characteristics be material!

Let us notice that the border can be limited to an elementary surface $\mathrm{d}A$ (we take A to avoid confusion with the entropy S) associated with its normal vector wrapping a fluid particle (see the section Marine and Weather Engineering for example!). We name it in this case "particulate border".

It is often useful in thermodynamics, to the energy accounting that is transferred between the thermodynamic system and the external environment, that is to say, consider everything that crosses the border!

The main type of transfers (but not the only one!) that may be made are:

1. The "work transfer W": (Mechanical) Work that operate most of time at macroscopic level done by a force over a distance. When no work transfer (energy) is operated on a macroscopic scale, the system is named "system without work".
2. The "heat-transfer Q": (agitation) Energy from the variation in the number of microstates at the microscopic scale (see section Mechanical Statistics page 3549). When no heat-transfer (energy) is operated at the microscopic level, the system is named "adiabatic system", otherwise it is said "diathermal".
3. The "mass transfer M": mass injected into the system. When no mass transfer is made, the system is named a "closed system".

Definitions (#9.6.458):

D1. An "isolated system" can not exchange neither work nor heat nor mass with its surroundings.

D2. An "open system" can exchange work, heat and mass with its surroundings.

D3. A "closed system" can share work and heat but no matter with its surroundings.

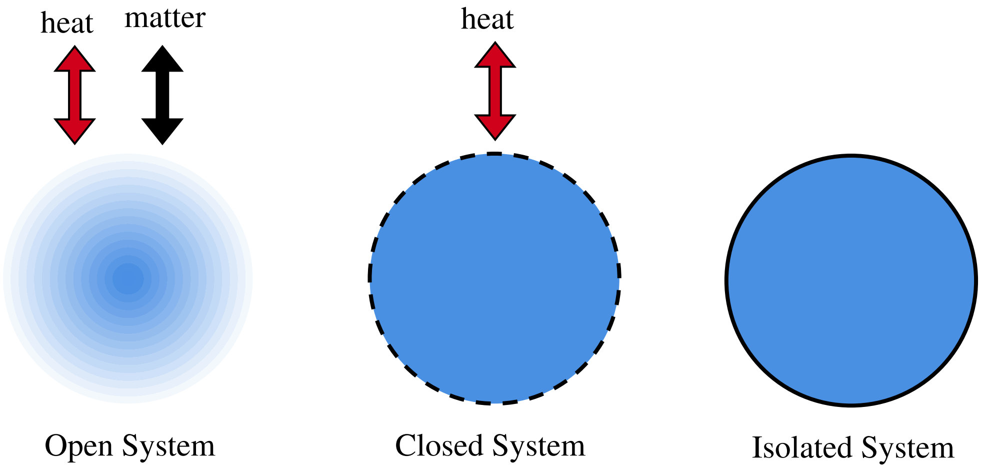

Figure 9.154: **Common type of thermodynamic systems**

Remarks

R1. Some systems count a bilan of external actions applied to them that is equal to zero. They are then say to be "pseudo-isolated".

R2. We speak of "homogeneous system" if the nature of its constituents is equal in every point, it is a "uniform system" or "isotropic system" if its characteristics are equal in every point.

9.6.3 Thermodynamic Transformations

Definition (#9.6.459): A "thermodynamic transformation" is the operation in which the system state changes passing from an initial state to a final state.

We distinguish at least two main types:

1. The "quasi-static thermodynamic transformation" that brings a system from an initial state to a final state through a succession of states that are exclusively equilibrium states (assumed as very slow transformation).

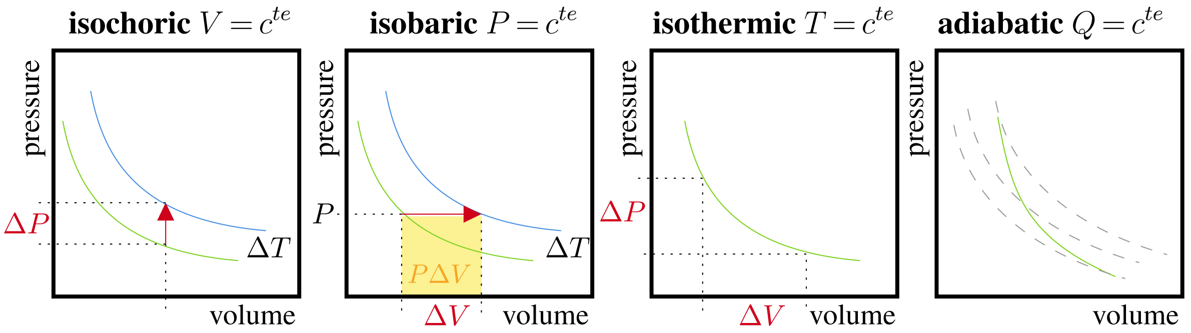
2. The transformations where all state variables change simultaneously are named "polytropic transformations".

It is possible that some variables remain constant during a thermodynamic transformation. In this case, we use very specific denominations:

Symbol	Description	Denomination
Q	Heat	Adiabatic
P	Pressure	Isobar
T	Absolute temperature	Isotherm
V	Volume	Isochore
U	Internal Energy	Isoenergetic
S	Entropy	Isentropic
H	Enthalpy	Isenthalpic
G	Free enthalpy	Extensive

Table 9.23: **Denomination of common constant systems**

Or visually with more relationships that we will prove further below:



isochoric $V = c^{te}$

adiabatic $Q = c^{te}$
pressure
volume

$$\begin{aligned}&\Delta P = nr\Delta T\\ &\mathrm{d}Q = \mathrm{d}U\\ &\mathrm{d}W = 0\\ &\mathrm{d}Q = nC_V\mathrm{d}T\end{aligned}$$

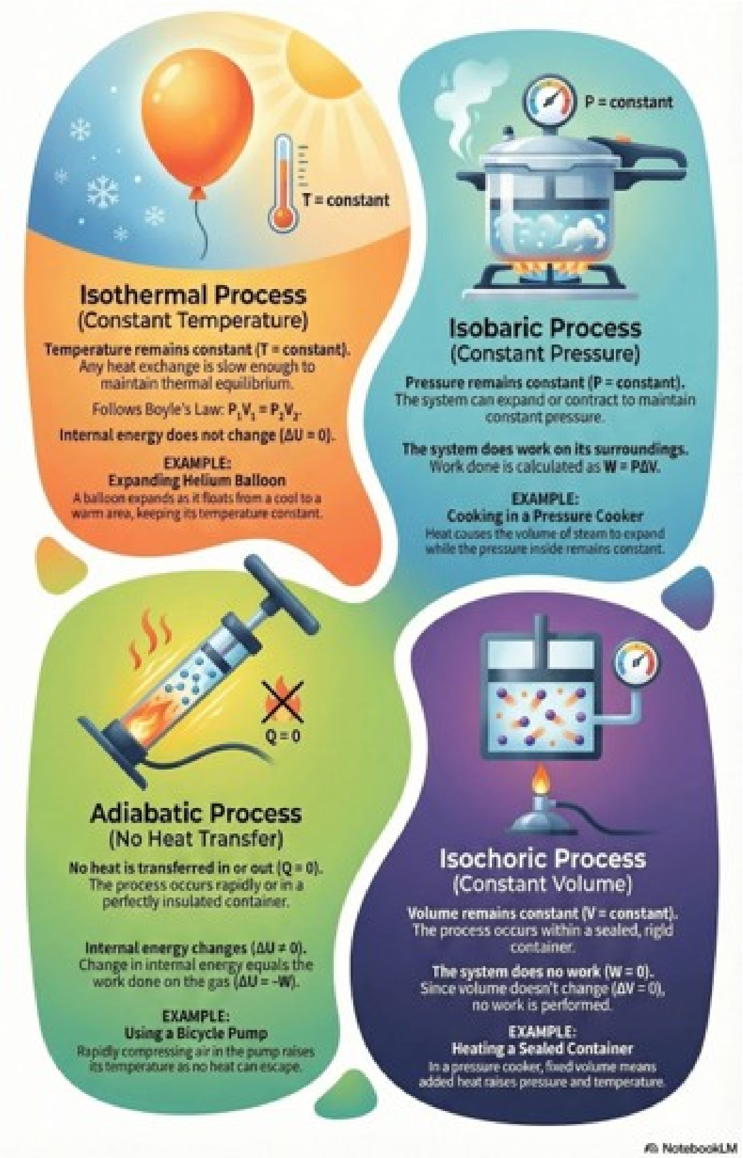
$$\begin{aligned}&\Delta \mathrm{V} = \mathrm{nr}\Delta \mathrm{T}\\ &\mathrm{d}H = \mathrm{d}Q - V\mathrm{d}P = \mathrm{d}Q\\ &\mathrm{d}W = P\mathrm{d}V\\ &\mathrm{d}U = \mathrm{d}Q - W\\ &\mathrm{d}Q = nC_V\mathrm{d}T\end{aligned}$$

$$\begin{aligned}&\Delta \mathrm{P}\Delta \mathrm{V} = \mathrm{c}^{\mathrm{te}}\\ &\mathrm{d}Q = -P\mathrm{d}V\\ &\mathrm{d}U = \mathrm{d}H = 0\\ &\mathrm{d}Q = \mathrm{d}W\\ &\Delta W = nR\ln\left(\frac{V_2}{V_1}\right)\end{aligned}$$

$$\begin{aligned}&\Delta P\Delta V = nR\Delta T\\ &\mathrm{d}Q = 0\\ &\mathrm{d}U = -P\mathrm{d}V\\ &\mathrm{d}H = V\mathrm{d}P\\ &\mathrm{d}U = -\mathrm{d}W\\ &\Delta W = -\frac{C_V}{R}(P_2V_2 - P_1V_1)\end{aligned}$$

Figure 9.155: **Most common type of thermodynamic processes illustrated**

Caution!!! An adiabatic transformation may be reversible (i.e. both the system and its environment can return to exactly the states they were in by following the reverse path) or irreversible (i.e. both the system and its environment cannot return together to exactly the states that they were in by following the reverse path), while an isothermal transformation is reversible for ideal gas.



Isothermal Process
(Constant Temperature)

Temperature remains constant (T = constant). Any heat exchange is slow enough to maintain thermal equilibrium.

Follows Boyle's Law: $P_1V_1 = P_2V_2$.

Internal energy does not change ($\Delta U = 0$).

EXAMPLE:
Expanding Helium Balloon
A balloon expands as it floats from a cool to a warm area, keeping its temperature constant.

Isobaric Process
(Constant Pressure)

Pressure remains constant (P = constant). The system can expand or contract to maintain constant pressure.

The system does work on its surroundings. Work done is calculated as $W = P\Delta V$.

EXAMPLE:
Cooking in a Pressure Cooker
Heat causes the volume of steam to expand while the pressure inside remains constant.

Adiabatic Process
(No Heat Transfer)

No heat is transferred in or out ($Q = 0$). The process occurs rapidly or in a perfectly insulated container.

Internal energy changes ($\Delta U \neq 0$). Change in internal energy equals the work done on the gas ($\Delta U = -W$).

EXAMPLE:
Using a Bicycle Pump
Rapidly compressing air in the pump raises its temperature as no heat can escape.

Isochoric Process
(Constant Volume)

Volume remains constant (V = constant). The process occurs within a sealed, rigid container.

The system does no work ($W = 0$). Since volume doesn't change ($\Delta V = 0$), no work is performed.

EXAMPLE:
Heating a Sealed Container
In a pressure cooker, fixed volume means added heat raises pressure and temperature.

Figure 9.156: **Main thermodynamics processes at a glance**

Remarks

R1. The studies of isobars systems are of great practical interest since all systems in contact with the atmosphere are often, at equilibrium, naturally or forcibly at constant pressure (that is to say at the same pressure as the surrounding atmosphere!) in laboratories.

R2. It is quite difficult to build useful isothermal transformations. Keep the temperature constant requires excellent thermal contact or isolation and a long reaction time to keep the temperature uniform. This type of transformation will be in the real world, rather slow.

R3. Many real transformations are considered as adiabatic. It is enough for this that the container is well isolated or even the transformation is fast enough such that the heat exchanges are negligible.

Definition (#9.6.460): A "thermodynamic cycle" consists of a linked sequence of thermodynamic processes that involve transfer of heat and work into and out of the system, while varying pressure, temperature, and other state variables within the system, and that eventually returns the system to its initial state.

We also distinguish two main thermodynamic transformations cycles that are:

- The "closed thermodynamic cycle": the system described a series of transformations such as the final state and the initial state of the process are the same and the quantities and properties of the elements involved in the cycle are always the same.
- The "open thermodynamic cycle": the system describes a series of transformations such that the final state and the initial state of the process are also the same and the quantity and properties of the elements involved in the cycle are not always the same.

Below a figure with two illustrative examples (we will come back on the technical aspects further below):

9.6.4 State Variables

Definition (#9.6.461): The "thermodynamic state" of a system is the set of properties that characterize it, regardless of the shape of its border. The variables that describe the state of the system by knowing only the final and initial state of the latter are named most of time "state functions" or more frequently "state variables" and sometimes even "state quantities"... Intuitively, the state of a system describes enough about the system to determine its future behaviour in the absence of any external forces affecting the system.

Until now in fact we already worked with state variables. Indeed, in mechanical systems, the position coordinates and velocities of mechanical parts are typical state variables. Knowing these, it is possible to determine the future state of the objects in the system.

In thermodynamics state variables include temperature, pressure, volume, internal energy, enthalpy, and entropy. In contrast heat and work are not state functions, but "process functions".

As we will see in the chapter of Electrodynamics, in electronic circuits, the voltages of the nodes and the currents through components in the circuit are usually the state variables. In Social Sciences the population sizes (or concentrations) of plants, animals and resources (nutrients, organic material) are typical state variables.

Remark

Some state variables play a special role in the definition of equilibrium states of a system. These are accessible quantities, at the macroscopic scale, directly or indirectly through measuring instruments. These special state functions (such as pressure, temperature, volume, etc.) are named sometimes "state variables of thermodynamic system at equilibrium".

The previous definition implicitly assumes the existence of a state and state variables, that is to say, the system characteristic parameters are defined (or theoretically accessible in the sense of measurement) at any time and at any point of the system. This is far from being easy if we consider the rapid changes of events such as explosions.

This difficulty can be studied by hiding us behind the "hypothesis of the local sate": We assume that at any time, the characteristic quantities have locally the same expressions as in a stationary configuration, which implies that the time necessary to state changes are negligible relatively to the characteristics periods of evolution.

The choice of the state variables depends on the nature of the problem studied. Nevertheless, we can separate all of these state variables at least into two groups:

D1. State variables are say to be "extensive quantities", if their are proportion to the quantity of matter and therefore the to the number of atoms/molecules of the system that are used to define them (therefore there are additive). This is typically the case of the mass M, the volume V, the Entropy S, the energy E, etc.

This means the system could be divided into any number of subsystems, and the extensive property measured for each subsystem; the value of the property for the system would be the sum of the property for each subsystem.

D2. State variables are say to be "intensive quantities", if their are independent to the quantity of matter and therefore the to the number of atoms/molecules of the system that are used to define them (therefore there are not additive). This is typically the case of the pressure P, the temperature T, the density ρ, the color, etc.

An intensive property is a therefore a bulk property, meaning that it is a physical property of a system that does not depend on the system size or the amount of material in the system

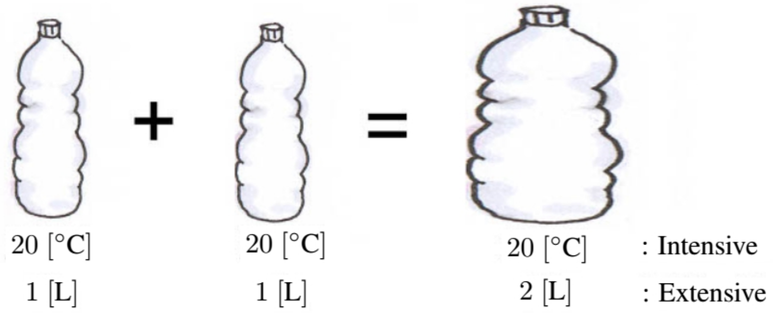

Figure 9.158: **Intensive vs Extensive variables**

In general, extensive variable depends on the point of view considered in the studied system while extensive variable are defined on the whole of the system.

Let us now show with a particular example that the ratio of two extensive variables is an intensive variable. For this, let us recall the ideal gas law (see section Continuum Mechanics page 3903) which is an equation of state (we will come back on state equations further below):

$$PV=N_{\text{Av}}nkT=nRT \tag{9.6.3}$$

which therefore includes three thermodynamic variables P, V and T (which leaves to us two choices of independent control variables and one dependent variable).

We can now calculate the concentration C (not to be confused with the notation of the heat capacity we will see later!), Which is therefore an intensive magnitude, by the ratio of two extensive quantities n, V such that:

$$C=\frac{n}{V}=\frac{P}{RT} \tag{9.6.4}$$

The state variables have also a special property: their variations are not dependent on the nature of the process that affects the system, but only the final and initial state of the system at equilibrium (which is very useful in practice ...!). This is the related to the concept of path integral that we have already discussed in detail in the section of Classical Mechanics and Differential and Integral Calculus.

Let us list the most familiar extensive and intensive quantities in thermodynamics:

Symbol	Legend	Quantity
Q	Heat	Extensive
P	Pressure	Intensive
T	Absolute temperature	Intensive
V	Volume	Extensive
E	Total Energy	Extensive
U	Internal Energy	Extensive
S	Entropy	Extensive
H	Enthalpy	Extensive
F	Free Energy	Extensive
G	Free enthalpy	Extensive

Table 9.24: **Common extensives and intensives state variables**

In contrast, the work W and heat Q are not a state variable because they depend on the nature of the transformation. However there are special cases where the heat and work are no longer dependent on the path followed when changes are made either at constant pressure or at constant volume (we will see this later).

9.6.4.1 Phases

Definitions (#9.6.462):

D1. A system in which various intensive variables vary continuously constitutes a "phase". In other words, a phase is a region of space (a thermodynamic system), throughout which all physical properties of a material are essentially uniform

We can therefore consider that any intensive magnitude depends only on the coordinates of the studied point: the system consists of a single phase if the intensive variable is continuous throughout the system. This is the case of gases, liquids and of some homogeneous solids.

D2. A "phase transition" is the transformation of a thermodynamic system from one phase or state of matter to another one by heat transfer. The term is most commonly used to describe transitions between solid, liquid and gaseous states of matter, and, in rare cases, plasma. A phase of a thermodynamic system and the states of matter have uniform physical properties. During a phase transition of a given medium certain properties of the medium change, often discontinuously, as a result of the change of some external condition, such as temperature, pressure, or others. For example, a liquid may become gas upon heating to the boiling point, resulting in an abrupt change in volume. The measurement of the external conditions at which the transformation occurs is termed the phase transition. Phase transitions are common in nature and used today in many technologies.

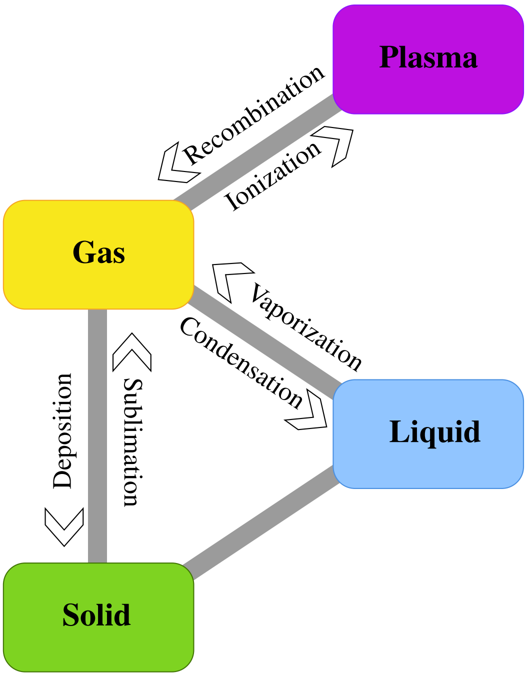

Figure 9.159: **Common phase transitions**

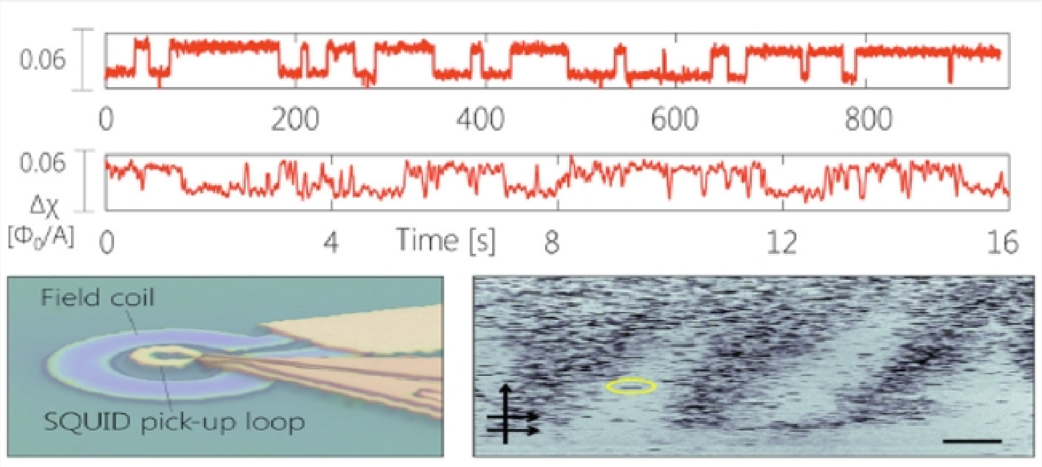
D3. If the intensive quantity has one discontinuity (or more), the system is said to be "multiphase". However, if the intensive quantities have the same value at any point in the system, the phase is said to be an "uniform phase": the system will have same temperature, pressure and composition in each of its points.

Remark

A "quantum phase transition" (QPT) occurs between two competing phases of matter at zero temperature, driven by quantum fluctuations. The presence of these fluctuations is well established (QPT represents quantum tunneling events between different states!), they have been locally imaged in space and their local dynamics has studied as they may be crucial for understanding why the structure of our universe is not homogeneous.

Scanning superconducting quantum interference device (SQUID) can be used to image quantum fluctuations in the vicinity of the QPT from a superconductor to an insulator (see [322]). Fluctuations of the diamagnetic response in both space and time that survive well below the transition temperature (in the figure below at $0.6T_c$), demonstrating their quantum nature.

By parking a SQUID (Superconducting Quantum Interference Device) over a superconducting elements it is possible to generated a map of the local diamagnetic susceptibility χ, revealing emergent puddles or regions where superconductivity is suppressed. The images reveal small streaks in the scan direction, which reflect dynamic events that can be tracked with an acquisition per pixel of 40 [ms]. The streaks manifest themselves as telegraph-like noise in the susceptibility signal with discrete jumps over a wide range of time scales (taken from [322]):



For a homogeneous system, it may be convenient to bring the extensive variables to the unit of mass. We speak then of "mass quantities" (or "specific quantities"), usually denoted in lower case.

We use if possible to avoid confusion the following scoring rules:

1. Any non-mass quantity is represented by an uppercase Latin letter $V, H, U, S, G, F, \ldots$ and then named respectively "volume", "enthalpy", "internal energy", "entropy", "free enthalpy", "free energy", and so on...
2. Any mass quantity is represented by a lowercase Latin letter $v, h, u, s, g, f, \ldots$ and then named respectively "specific volume", "specific enthalpy", "specific internal energy", "specific entropy", "specific free enthalpy", "specific free energy", and so on...

Otherwise, if we do not follow this notation, we will have to specify what type of variable we are dealing with.

Notice by the way that all specific variables are intensive variables!

9.6.5 Equation of State

In physics, particularly in thermodynamics, the "equation of state" of a system at thermodynamic equilibrium is a relation between different physical parameters, so named "state variables" already defined previously that determine its status. This may be for example of a relation between temperature, pressure and volume. From the characteristic equation of state of a physical system, it is possible to determine all the thermodynamic quantities describing this system and hence predict its properties.

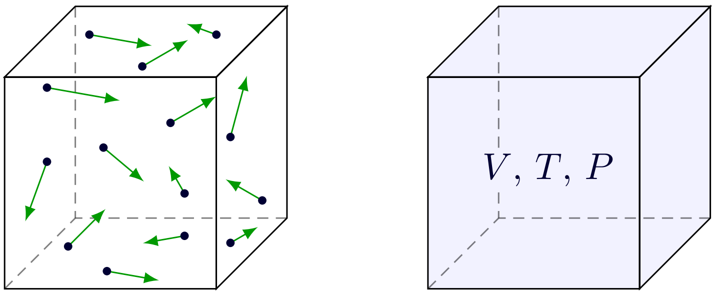
The equations of state are generally restricted to a type of behaviour or to given physical phenomena. One body can have several equations of state, for example the magnetic state or its thermodynamic state.

For a body to be characterized by an equation of state at a given time, it is necessary that the state of the body depends only of the values of the known parameters at this time. The body having a hysteresis phenomenon can not therefore be characterized by an equation of state.

9.6.5.1 Ideal Gas law

We have proved in the section of Continuum Mechanics (see page 3903) that the state equation of an ideal gas was (relation already introduced previously a little bit fortuitously earlier above):

$$\boxed{PV = nRT} \tag{9.6.5}$$



That is to say also:

$$V(P,T) = \frac{nRT}{P} \tag{9.6.6}$$

and the equation of state of real gases (also proved in the section of Continuum Mechanics):

$$\left(P + a\left(\frac{N}{V}\right)^2\right)(V - Nb) \cong kNT \tag{9.6.7}$$

To determine the particular and idealized equations of state of solids and liquids, it will first introduce several factors, named "thermo-elastic coefficients", used to characterize some global properties of these continuous media.

These coefficients should be defined carefully, depending on how we measure them, that is to say, depending on what is actually measured.

Let us take, for example, the concept of (volumetric) compressibility of a sample. It is reasonable to say that the underlying idea is the measurement of volume change under a change in pressure. If the pressure increases, the volume will decrease, so it seems reasonable to set a compressibility factor by:

$$\chi = -\frac{\partial V}{\partial P} \tag{9.6.8}$$

where the sign "$-$" is used to ensure a positive χ in the case of compression.

But this definition does not mean anything. We have not specified the conditions under which the measures are taken. Clearly, we increase (or diminish) the pressure measured using a manometer for example, and we measure with a ruler (!) the volume change that results. It sounds simple, but it is incomplete. If we increase the pressure fast enough, the volume will decrease but the temperature will increase. Do we measure the volume change immediately or we wait that the temperature is returned that it was by placing the sample in thermal contact with a thermostat that we used before measuring the volume change. In the latter case, the measurement has been made at constant temperature.

In other words, do we measure the volume change of a receptacle in perfect thermal contact with the external environment (we leave it the time to go to equilibrium) or thermally isolated from this environment. It is very different!

Furthermore, V being an extensive variable, there will be an advantage in defining the compressibility as an intensive quantity, that is to say independent of the amount of gas in question (here isothermal), which makes easier the construction of tables of values. We then have intuitively the following definition of the "(relative) isothermal coefficient of compressibility":

$$\chi_T=-\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \tag{9.6.9}$$

on which will be come back later more in details.

In the same intuitive we, we can define the "(relative) isobaric coefficient of compressibility" (more rarely named "(relative) volume isobaric coefficient of compressibility"):

$$\alpha_{V,P}=-\frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P \tag{9.6.10}$$

on which will be come back later more in details.

For example, for a perfect gas we have:

$$\alpha_{V,P}=\frac{1}{V}\left(\frac{\partial\left(\dfrac{nRT}{P}\right)}{\partial T}\right)_P=\frac{1}{V}\frac{nR}{P}=\frac{nR}{VP}=\frac{nR}{nRT}=\frac{1}{T} \tag{9.6.11}$$

We will later another approach to fall back on this equality.

9.6.5.2 State equation of a Liquid

Now the (macroscopic) state variables of a liquid are quite trivially the volume V, the pressure P and temperature T. Its equation of state can then be written in the form:

$$V=f(T,P) \tag{9.6.12}$$

Under differential form this give:

$$\mathrm{d}V=\left(\frac{\partial V}{\partial T}\right)_P\mathrm{d}T+\left(\frac{\partial V}{\partial P}\right)_T\mathrm{d}P \tag{9.6.13}$$

By introducing the thermoelastic coefficients as we did above, we get:

$$\frac{\mathrm{d}V}{V}=\alpha_{V,P}\mathrm{d}T-\chi_T\mathrm{d}P \tag{9.6.14}$$

Experience shows that for liquids, the thermoelastic coefficients vary very little with temperature and pressure (yes ... the experience is still useful sometimes ...). We can therefore assume them as constant, provided that the variations of the temperature and pressure are moderate. As the changes in volume of a liquid are very low when the transformations are slow, we can do the same approximation as that proved in the section of Continuum Mechanics with the true longitudinal deformation. Which means:

$$\frac{\mathrm{d}V}{V}\cong\frac{\mathrm{d}V}{V_0} \tag{9.6.15}$$

where V_0 is the constant reference volume. Taking into account these remarks, we get trivially by integration the general state equation of a liquid:

$$\boxed{V(T,P)=V_0[1+\alpha_{V,P}(T-T_0)-\chi_T(P-P_0)]} \tag{9.6.16}$$

Let us notice that the approximation of an (assumed...) incompressible liquid[23], commonly used in fluid dynamics, assume that:

$$\alpha_{V,P}=0 \qquad \chi_T=0 \tag{9.6.17}$$

The state equation of the liquid the becomes obviously:

$$V(T,P)=V_0=c^{te} \tag{9.6.18}$$

Let us also notice that in small classes, solids are considered sometimes as incompressible liquids. We then have the famous relation known by many students under the name of "volumetric dilatation formula":

$$\boxed{V(T,P)=V_0[1+\alpha_{V,P}(T-T_0)]} \tag{9.6.19}$$

These two formulations are exactly the same that the technical formulation of the Gay-Lussac law for gas (see section Continuum Mechanics page 3892).

We can do again the same reasoning with an element of length but by defining another thermoelastic coefficient: a linear one this time! Therefore, it comes another famous relation known by many students under the name of "length dilatation formula":

$$\boxed{\Delta L=\alpha_{L,P}L_0\Delta T} \tag{9.6.20}$$

We can then determine the relation between $\alpha_{L,P}$ and $\alpha_{V,P}$ (which are both much small than the unit as far as we know). Indeed, for a cube of sides L, we have:

$$\begin{aligned}\Delta V&=(L_0+\Delta L)^3-L_0^3=(L_0+\alpha_{L,P}L_0\Delta T)^3-L_0^3=L_0^3(1+\alpha_{L,P}\Delta T)^3-L_0^3\\&=L_0^3\left(1+3\alpha_{L,P}\Delta T+\underbrace{3\alpha_{L,P}^2\Delta^2}_{\to 0}+\underbrace{\alpha_L^3\Delta T^3}_{\to 0}\right)-L_0^3\cong 3\alpha_{L,P}L_0^3\Delta T\end{aligned} \tag{9.6.21}$$

---

[23] Keep in mind that even water is compressible otherwise sound wouldn't propagate in the latter...! In deep oceans for example the water is compressed by a factor of approximately 1.9%.

and therefore it comes:

$$\boxed{3\alpha_{L,P} \cong \alpha_{V,P}} \tag{9.6.22}$$

We have for example for water at room temperature:

$$\alpha_{V,P} \cong 2.6 \cdot 10^{-4}\,[\text{K}^{-1}] \qquad \chi_V \cong 4.5 \cdot 10^{-7}\,[\text{Pa}^{-1}] \tag{9.6.23}$$

✍**Example:**

A tank of volume V, with walls supposed non-deformable, is completely filled with water initially in thermodynamic equilibrium with the initial pressure P_0 of 1 [bar] and at the initial temperature T_0 of 298 [K]. After having received a certain amount of heat, the liquid reaches a new state of thermodynamic equilibrium, at the temperature of 398 [K]. We then have since $V=V_0$, the liquid state equation that reduces to:

$$\frac{V(T,P)}{V_0}=1=[1+\alpha_{V,P}(T-T_0)-\chi_V(P-P_0)] \tag{9.6.24}$$

Or after rearrangement:

$$P=\frac{\alpha_{V,P}}{\chi_V}(T-T_0)+P_0 \cong 1.58\,[\text{bar}] \tag{9.6.25}$$

Remark

The Eiffel Tower for example was well designed: it can oscillates because of the wind of ± 28 [cm], it can dilates vertically of ± 17 [cm] and because of the thermal radiation and of the path of the Sun (actually a G2V-type star, aka yellow dwarf) in the sky during a day it describes and ellipse of ± 18 [cm].

9.6.5.3 State equation of Solids

Let us now consider the special case of a beam (or a string) composed of an elastic material. The typical state variables of the system are then its length L, its temperature T and the tensile force F (positive in the case of traction and negative in the case of compression by convention). The equation of state is thus put in the following differential form:

$$\mathrm{d}L=\left(\frac{\partial L}{\partial T}\right)_F \mathrm{d}T+\left(\frac{\partial L}{\partial F}\right)_T \mathrm{d}F \tag{9.6.26}$$

By analogy with isobaric volumetric expansion coefficient $\alpha_{V,P}$, we define the "coefficient of linear expansion":

$$\alpha_{L,F}=\frac{1}{L}\left(\frac{\partial L}{\partial T}\right)_F \tag{9.6.27}$$

Furthermore, we proved in the section of Continuum Mechanics, that for an isothermal tensile test (without tangential component) performed on an elastic material we have (implicitly it is the Hooke's law for recall):

$$\frac{|\Delta L|}{L_0}=\frac{F/S}{E}=\frac{F}{ES} \tag{9.6.28}$$

But we can also use the true longitudinal deformation afterwards it is then obviously necessary to adapt the right term accordingly:

$$\frac{\mathrm{d}L}{L}=\frac{\mathrm{d}F}{ES} \tag{9.6.29}$$

Therefore it comes:

$$\frac{1}{ES}=\frac{1}{L}\left(\frac{\partial L}{\partial F}\right)_T \tag{9.6.30}$$

The state equation of solids can then be written by injecting inside the latter relation:

$$\frac{\mathrm{d}L}{L}=\alpha_{L,F}\mathrm{d}T+\frac{\mathrm{d}F}{ES} \tag{9.6.31}$$

This relation gives us the variation of relative elongation corresponding to an infinitesimal change of the tensioning force and of the temperature, knowing the linear expansion coefficient .

The above state equation is easily integrated assuming that the coefficient of linear expansion, Young's modulus and sectional area are constant (let us know as always if you want the details):

$$\boxed{L=L_0e^{\alpha_L\Delta T+\frac{\Delta F}{ES}}=L_0e^{\alpha_L\Delta T}e^{\frac{\Delta F}{ES}}} \tag{9.6.32}$$

If the deformations are very small, we have proved in the section of Continuum Mechanics that the relative variation of elongation could be written:

$$\frac{\mathrm{d}L}{L}\cong\frac{\mathrm{d}L}{L_0} \tag{9.6.33}$$

$$\frac{\mathrm{d}L}{L_0}=\alpha_{L,F}\mathrm{d}T+\frac{\mathrm{d}F}{ES} \tag{9.6.34}$$

So after integration:

$$\boxed{\frac{\Delta L}{L_0}=\alpha_{L,F}\Delta T+\frac{\Delta F}{ES}} \tag{9.6.35}$$

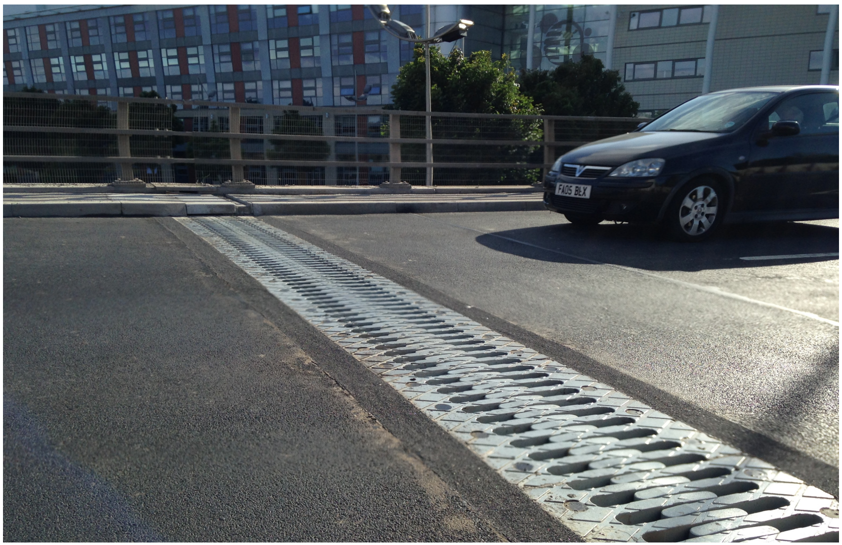


Figure 9.160: **Thermal expansion joints like these allow bridges to change length without buckling (source: ?)**

✍**Example:**

A cylindrical steel beam of radius 15 [mm] is initially in a state of thermodynamic equilibrium characterized by an initial length of 1 [m] at the initial temperature of 300 [K] and a zero initial tension force. The beam is heated to a new equilibrium in which the final temperature is 400 [K]. To calculate the new length in the particular case that the beam is free to move and that the deformation is considered as small:

$$\frac{L-L_0}{L_0}=\alpha_L(T-T_0)+\frac{\overbrace{\Delta F}^{}_{\cong 0}}{ES} \tag{9.6.36}$$

Therefore:

$$L=L_0\alpha_L(T-T_0)+L_0=1\cdot 12\cdot 10^{-6}\cdot 100+1=1.0012\,[\text{m}] \tag{9.6.37}$$

If the beam is embed at the both sides, we can then calculate the internal stress force generated ("thermal stress") under the assumption of small deformations. We then use:

$$\frac{\underbrace{\Delta L}_{\cong 0}}{L_0}=\alpha_L(T-T_0)+\frac{\Delta F}{ES} \tag{9.6.38}$$

Therefore:

$$\begin{aligned}F&=-\alpha_L ES(T-T_0)+F_0=-\alpha_L ES(T-T_0)\\&=-12\cdot 10^{-6}\cdot 2\cdot 10^{11}\pi\cdot 0.015^2\cdot 100\cong 170\,[\text{kN}]\end{aligned} \tag{9.6.39}$$

We see here a phenomenon well known in mechanical engineering: the thermal deformation of a solid is usually very small, but prevent it can generate tremendous efforts, that could destroy a mechanism.

9.6.6 Laws of Thermodynamics

The principles of thermodynamics are the bricks of thermal or mechanical energy. Each principle involves a lot of concepts that we will try to present and define as best as we can further below. This is the "sensitive" part of this field of physics.

Thermodynamics is based on four basic laws (some of which are provable):

P0. The "zeroth law of thermodynamics" or "principle of thermal equilibrium" is defined by the fact that if two thermodynamic systems 1 and 2 are in thermodynamic equilibrium with a third one 3, they are themselves in thermodynamic equilibrium (it is an "assertion" in the language of Proof Theory). This can be denoted formally by:

$$\boxed{\lim_{t\to+\infty} T_{M_1}(t,T_{M_2})=\lim_{t\to+\infty} T_{M_2}(t,T_{M_1})} \tag{9.6.40}$$

So if two materials in contacts are in thermal equilibrium, they have the same temperature and thus the state remains stationary. Two materials at the same temperature in contact are in thermal equilibrium.

> **Remark**
>
> We used this principle implicitly (when we stated that the steady state was the most likely one) in the section of Statistical Mechanics to prove the Boltzmann law.

P1. The "first law of thermodynamics" or "conservation principle" refers to the conservative nature of energy and states that during any of a system transformation, the change in its total energy is equal to the sum of changes in all types of energy defining it:

$$\boxed{\Delta E_{\text{tot}}=\Delta U+\Delta E_c+\Delta E_p} \tag{9.6.41}$$

If the system is isolated then the change in total energy will obviously always be zero (in average...)!

> **Remark**
>
> Depending on the authors, the kinetic energy and potential energy are part of the internal energy U.

Of course, when the system studied (the container and its content) are in the same repository as the observer, it remains only the term of internal energy variation:

$$\boxed{\Delta E_{\text{tot}}=\Delta U} \tag{9.6.42}$$

or in differential terms:

$$\mathrm{d}E_{\text{tot}}=\mathrm{d}U \tag{9.6.43}$$

It remains to determine the exact expression of the change in internal energy U and variables on which it depends (developments that we will do a little further below).

Remark

This principle is provable if we accept Noether's theorem (see section Principia page 3132) on time invariance of physics laws of physics as a higher principle.

P2. The "second law of thermodynamics" also named "Carnot-Clausius' principle" or "principle of evolution" refers to the irreversible nature and is associated with the concept of entropy. This principle, the most famous one, states that heat can only pass itself from a warm body to a cooler body (or a body will inevitably be cooler with time) in a closed system (i.e. without increase or decrease of energy) in a non-changing space-time. The reverse operation requiring the contribution of mechanical work took on the external system that is given by equation (proved a little further below):

$$\boxed{\mathrm{d}S=\frac{\delta Q}{T}\geq 0} \tag{9.6.44}$$

The left hand side of equality states that entropy can only increase and that the amount of heat exchange with the external system is always positive (numerator term right to equality). Therefore the body delivers heat to the external system and cooled down inexorably.

The special notation δQ is here to indicate that heat is an inaccurate total differential. This is a concept to which we will return further below.

Remark

We will prove roughly ... this relation further below by using the Boltzmann law on the access to the information in a system such as studied in the section of Statistical Mechanics.

P3. The "third law of thermodynamics" also named "Nernst principle" concern the properties of matter in the vicinity of absolute zero and states that at the limit of the absolute zero temperature that can not be reached (see section Wave Quantum Physics page 4814), the equilibrium entropy of a system approaches a constant independent of the other intensive parameters, constant that is taken as zero. Or in other words: The entropy of a perfect crystal at absolute zero is exactly equal to zero.

Proof 9.10.4. This statement is based on the proof of the "Nernst theorem" which formal result is simply based on the second law giving the entropy (see section Statistical Mechanics page 3553):

$$S=k\ln(\Omega) \tag{9.6.45}$$

We see that if we consider a crystal at absolute zero temperature, the particles position against each other are perfectly uniquely defined. Therefore, there is only one possible complexion for crystal at absolute zero. The number of complexions Ω is equal to 1. This gives us:

$$\boxed{S=k\ln(1)=0} \tag{9.6.46}$$

■ Q.E.D.

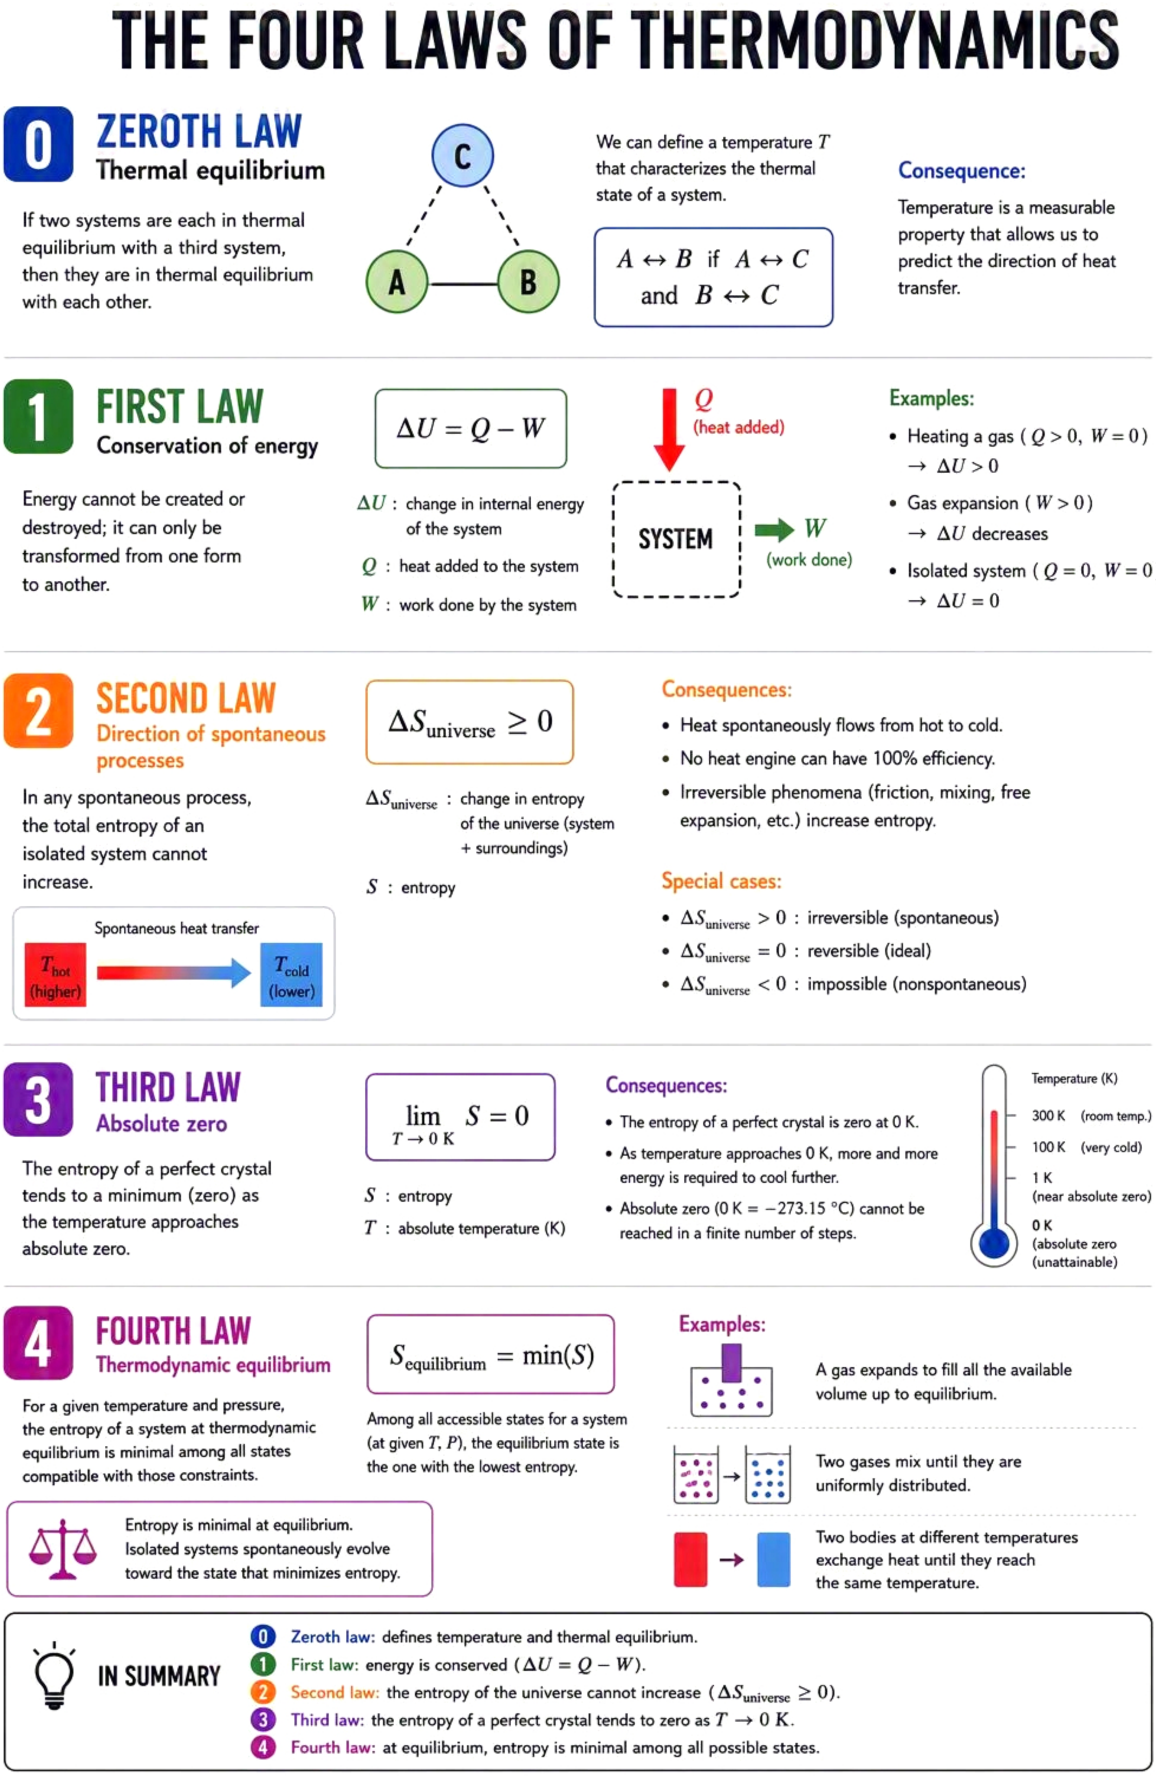
Let us recall that the "absolute zero" seems to be the lowest temperature experimentally reachable (theoretically - using quantum information theory - the value is derived by the fact we should need an infinite amount of energy to reach it) available in physics. At this temperature a substance no longer contains, at a macroscopic scale, the thermal energy (or heat) required for the occupation of several microscopic energy levels (see section Statistical Mechanics page 3549). The particles that make it up (atoms, molecules) are all in the same minimum energy state (ground state). This results in a null entropy due to the indistinguishability of the particles in the same fundamental energy level of entropy (following the third law of thermodynamics) and a total immobility in the conventional sense following the virial theorem (see section Continuum Mechanics page 3897).

However, in the quantum point of view, we will see in the section of Wave Quantum Physics that particles always have a non-zero linear momentum following the Heisenberg uncertainty relations and that following the Fermi-Dirac and Bose-Einstein distributions (see section Statistical Mechanics page 3571 and page 3576), there are still different energy levels when we take into account the Pauli exclusion principle. Hence the emergence of quantum thermodynamics.

Remark

A common question that arise is why the zeroth law of thermodynamics is named "zeroth law", why didn't physicists start the counting from one as in almost all other fields of physics? Indeed laws of physics are numbered according to their fundamental nature, the more fundamental the law, the higher it is in the pecking order of the laws. E.g., Newton gave the three laws of motion in one go, but he numbered the First Law of motion as the "first law" because it was the most fundamental of all the three law. Without understanding the first law, you cannot go to the second and the third laws.

As far as Thermodynamics is concerned, the First Law had been in currency and had been accepted for long. But when some scientist postulated the (now named) "Zeroth law", the scientific community came to the conclusion that this new law is more fundamental than the First Law because it provides the basis for defining an entity named "Temperature". So they decided to name it the "Zeroth Law", i.e. more fundamental than the First Law.



THE FOUR LAWS OF THERMODYNAMICS

0 ZEROTH LAW
Thermal equilibrium

If two systems are each in thermal equilibrium with a third system, then they are in thermal equilibrium with each other.

We can define a temperature T that characterizes the thermal state of a system.

$$\boxed{A \leftrightarrow B \text{ if } A \leftrightarrow C \text{ and } B \leftrightarrow C}$$

Consequence:

Temperature is a measurable property that allows us to predict the direction of heat transfer.

1 FIRST LAW
Conservation of energy

Energy cannot be created or destroyed; it can only be transformed from one form to another.

$$\boxed{\Delta U = Q - W}$$

ΔU : change in internal energy of the system

Q : heat added to the system

W : work done by the system

Examples:

- Heating a gas ($Q > 0,\ W = 0$) → $\Delta U > 0$
- Gas expansion ($W > 0$) → ΔU decreases
- Isolated system ($Q = 0,\ W = 0$) → $\Delta U = 0$

2 SECOND LAW
Direction of spontaneous processes

In any spontaneous process, the total entropy of an isolated system cannot increase.

Spontaneous heat transfer
T_{hot} (higher)
T_{cold} (lower)

$$\boxed{\Delta S_{\text{universe}} \geq 0}$$

$\Delta S_{\text{universe}}$: change in entropy of the universe (system + surroundings)

S : entropy

Consequences:

- Heat spontaneously flows from hot to cold.
- No heat engine can have 100% efficiency.
- Irreversible phenomena (friction, mixing, free expansion, etc.) increase entropy.

Special cases:

- $\Delta S_{\text{universe}} > 0$: irreversible (spontaneous)
- $\Delta S_{\text{universe}} = 0$: reversible (ideal)
- $\Delta S_{\text{universe}} < 0$: impossible (nonspontaneous)

3 THIRD LAW
Absolute zero

The entropy of a perfect crystal tends to a minimum (zero) as the temperature approaches absolute zero.

$$\boxed{\lim_{T \to 0\,\text{K}} S = 0}$$

S : entropy

T : absolute temperature (K)

Consequences:

- The entropy of a perfect crystal is zero at 0 K.
- As temperature approaches 0 K, more and more energy is required to cool further.
- Absolute zero (0 K = −273.15 °C) cannot be reached in a finite number of steps.

4 FOURTH LAW
Thermodynamic equilibrium

For a given temperature and pressure, the entropy of a system at thermodynamic equilibrium is minimal among all states compatible with those constraints.

$$\boxed{S_{\text{equilibrium}} = \min(S)}$$

Among all accessible states for a system (at given T, P), the equilibrium state is the one with the lowest entropy.

Entropy is minimal at equilibrium. Isolated systems spontaneously evolve toward the state that minimizes entropy.

Examples:

A gas expands to fill all the available volume up to equilibrium.

Two gases mix until they are uniformly distributed.

Two bodies at different temperatures exchange heat until they reach the same temperature.

IN SUMMARY

- ⓪ Zeroth law: defines temperature and thermal equilibrium.
- ① First law: energy is conserved ($\Delta U = Q - W$).
- ② Second law: the entropy of the universe cannot increase ($\Delta S_{\text{universe}} \geq 0$).
- ③ Third law: the entropy of a perfect crystal tends to zero as $T \to 0$ K.
- ④ Fourth law: at equilibrium, entropy is minimal among all possible states.

Figure 9.161: Summary of the four laws of the thermodynamics

9.6.7 Calorific Capacities (heat capacity)

In a given transformation, an intake of heat ΔQ generally results in a raising ΔT of the temperature of the system.

Definition (#9.6.463): We name "heat capacity" (or "calorific capacity", or "thermal capacity") C of system, the quantity:

$$\boxed{C=\frac{\Delta Q}{\Delta T}} \tag{9.6.47}$$

The heat capacity is therefore by its units, the energy it takes to bring a body to increase its temperature by 1 Kelvin. Under infinitesimal form, we have:

$$\boxed{C=\frac{\delta Q}{\partial T}} \tag{9.6.48}$$

We see that the educational benefit of having a notation using discrete variations rather than infinitesimal allows us not have to ask the question if we have an exact total differential or inaccurate one... (see below for the distinction).

Heat capacity is obviously an extensive property of matter, meaning it is proportional to the size of the system. When expressing the same phenomenon as an intensive property, the heat capacity is divided by the amount of substance, mass, or volume, so that the quantity is independent of the size or extent of the sample:

$$\boxed{c=\frac{\Delta Q}{\Delta T}\frac{1}{M}} \tag{9.6.49}$$

and then we speak of "specific heat".

The molar heat capacity is the heat capacity per unit amount (SI unit: mole) of a pure substance (see section Analytical Chemistry page 6228).

In the case of an ideal gas, we assume that all of the exchanged heat (energy) is changed into kinetic energy of the atoms or molecules (thermal energy), so we can write:

$$C=\frac{\Delta Q}{\Delta T}=\frac{\Delta U}{\Delta T}=\frac{\Delta E_c}{\Delta T} \tag{9.6.50}$$

and we will prove later how to determine the exact value of this capability for such gas.

However, let us already see how to determine this heat capacity for crystalline solids (which we will assume at constant volume). To do this, remember that we proved in the chapter of Electrokinetics (see page 4279) that in a crystal, the density of states in a volume under certain very specific conditions was:

$$D(\omega)=\frac{\mathrm{d}N}{\mathrm{d}k}\frac{\mathrm{d}k}{\mathrm{d}\omega}=\frac{Vk^2}{2\pi^2}\frac{\mathrm{d}k}{\mathrm{d}\omega} \tag{9.6.51}$$

and the number of related states was given by:

$$N=\frac{k^3}{6\pi^2}V \tag{9.6.52}$$

However, the prior-previous relation is independent of the fact that in the field of electrokinetic we consider the electron or any other particle vector of some property (electric charge, heat or other). Thus in the context of the thermodynamic crystalline solids, a model consist to assume the heat vector as a particle having similar wave properties to that of an electron that it is customary to name a "phonon".

Assuming that the phonons are identical in all three spatial directions and remembering the Planck-Einstein relation (see section Corpuscular Quantum Physics page 4627) valid for any particle by the principle of wave-particle duality:

$$E=h\nu \tag{9.6.53}$$

and (see section Statistical Mechanics page 3576) from the Bose-Einstein statistics for bosons (particles not subjected to the Pauli exclusion principle for recall ...):

$$f_{\text{BE}}(E,T,\mu)=\frac{1}{e^{\frac{E-\mu}{kT}}-1} \tag{9.6.54}$$

which we write in the present case as following (since the chemical potential is zero in our case):

$$n(\omega)=\frac{1}{e^{\frac{E}{kT}}-1}=\frac{1}{e^{\frac{h\nu}{kT}}-1}=\frac{1}{e^{\frac{\hbar\omega}{kT}}-1} \tag{9.6.55}$$

we have by combining these three big results:

$$U=3\int\limits_{\omega}h\nu(\omega)D(\omega)\mathrm{d}\omega=3\int\limits_{\omega}h\frac{\omega}{2\pi}n(\omega)D(\omega)\mathrm{d}\omega=3\int\limits_{\omega}\hbar\omega n(\omega)D(\omega)\mathrm{d}\omega=3\int\limits_{\omega}\frac{\hbar\omega}{e^{\frac{\hbar\omega}{kT}}-1}D(\omega)\mathrm{d}\omega \tag{9.6.56}$$

Then we have:

$$\begin{aligned}C_V&=\left(\frac{\delta Q}{\partial T}\right)_V=\left(\frac{\mathrm{d}U-\delta W}{\partial T}\right)=\left(\frac{\mathrm{d}U-P\underbrace{\mathrm{d}V}_{=0}}{\partial T}\right)=\left(\frac{\mathrm{d}U}{\partial T}\right)_V\\&=3\int\limits_{\omega}\hbar\omega\frac{\partial}{\partial T}\left(\frac{1}{e^{\hbar\omega/kT}-1}\right)D(\omega)\mathrm{d}\omega=3\int\limits_{\omega}\hbar\omega\left(\frac{\hbar\omega}{kT}\frac{e^{\hbar\omega/kT}}{\left(e^{\hbar\omega/kT}-1\right)^2}\right)D(\omega)\mathrm{d}\omega\\&=3\int\limits_{\omega}\hbar\omega\left[-\frac{1}{\left(e^{\hbar\omega/kT}-1\right)^2}\left(-\frac{\hbar\omega}{kT^2}e^{\hbar\omega/kT}\right)\right]D(\omega)\mathrm{d}\omega\\&=3k\int\limits_{\omega}\left(\frac{\hbar\omega}{kT}\right)^2\frac{e^{\hbar\omega/kT}}{\left(e^{\hbar\omega/kT}-1\right)^2}D(\omega)\mathrm{d}\omega\end{aligned} \tag{9.6.57}$$

From here there are two main models for predicting the heat capacity of crystals, the "Debye model" and the "Einstein model", each making assumptions about the density of phonon modes. The Debye model treats the vibrations of the atomic lattice (heat) - named "Debye solid" as phonons in a box, in contrast to the Einstein (photoelectron) model, which treats the solid - named "Einstein solid" as many individual, non-interacting quantum harmonic oscillators.

In the Einstein model a single frequency mode (respectively pulsation) is supposed possible, so that the vibration of the solid is represented by N harmonic oscillators at this frequency. This particular pulse is often associated with what we name the "Einstein temperature" (also often denoted T_E):

$$\Theta_E=\frac{\hbar\omega_E}{k} \tag{9.6.58}$$

The density of modes is then symbolized by N Dirac distributions (see section Differential and Integral Calculus page 1569) around such that:

$$\begin{aligned}C_V&=3k\int\limits_{\omega}\frac{e^{\hbar\omega/kT}}{(e^{\hbar\omega/kT}-1)^2}N\delta(\omega_E)\mathrm{d}\omega=3kN\left(\frac{\hbar\omega_E}{kT}\right)^2\frac{e^{\hbar\omega_E/kT}}{(e^{\hbar\omega_E/kT}-1)^2}\\&=3kN\left(\frac{\Theta}{T}\right)^2\frac{e^{\Theta/T}}{(e^{\Theta/T}-1)^2}\end{aligned} \tag{9.6.59}$$

This model provides a limit value of the heat capacity at high temperatures (we use a Taylor series approximation):

$$\begin{aligned}C_{V,T\rightarrow+\infty}&\cong3kN\left(\left(\frac{\hbar\omega}{kT}\right)^2\frac{1+\dfrac{\hbar\omega}{kT}}{\left(\left(1+\dfrac{\hbar\omega}{kT}\right)-1\right)^2}\right)=3kN\left(\left(\frac{\hbar\omega}{kT}\right)^2\frac{1+\dfrac{\hbar\omega}{kT}}{\left(\dfrac{\hbar\omega}{kT}\right)^2}\right)\\&=3kN\left(1+\frac{\hbar\omega}{kT}\right)\cong3kN\end{aligned} \tag{9.6.60}$$

It is customary when we presented this relation to consider a quantity of material corresponding to a mole to make appear the ideal gas constant:

$$\boxed{C_{V,T\rightarrow+\infty}\cong3kN_{\text{A}}=3R} \tag{9.6.61}$$

This value was originally given by Dulong and Petit and is in fairly good agreement with experimental results. We often talk about the "Dulong-Petit law".

In contrast at low temperatures, it is necessary to use the Debye model that consist to assume as linear dispersion relation with the speed of propagation of phonons (speed of sound in the crystal) supposed to be independent of temperature:

$$\omega(k)=vk \tag{9.6.62}$$

The density of states is then written:

$$D(\omega)=\frac{Vk^2}{2\pi^2}\frac{\mathrm{d}k}{\mathrm{d}\omega}=\frac{Vk^2}{2\pi^2}\frac{\mathrm{d}\left(\dfrac{\omega}{v}\right)}{\mathrm{d}\omega}=\frac{Vk^2}{2\pi^2v}=\frac{V\left(\dfrac{\omega}{v}\right)^2}{2\pi^2v}=\frac{V\omega^2}{2\pi^2v^3} \tag{9.6.63}$$

We then have for the heat capacity:

$$U=3\int\limits_{\omega}\hbar\omega\frac{1}{e^{\hbar\omega/kT}-1}\frac{V\omega^2}{2\pi^2v^3}\mathrm{d}\omega=\frac{3V\hbar}{2\pi^2v^3}\int\limits_{\omega}\frac{\omega^3}{e^{\hbar\omega/kT}-1}\mathrm{d}\omega \tag{9.6.64}$$

In the Debye model, only the acoustic phonon branch is considered, this is equivalent to schematize the crystal as a mono-atomic network formed of heavy atoms. Therefore, the resonance modes are limited to a certain frequency (pulse), with the corresponding volume, known as "cutting frequency" (we change the notation of the Boltzmann constant in K_B so to confuse it with the wave number k):

$$\begin{aligned}U&=\frac{3V\hbar}{2\pi v^3}\int\limits_0^{\omega_D}\frac{\omega^3}{e^{\hbar\omega/kT}-1}\mathrm{d}\omega=\frac{3V\hbar}{2\pi^2v^3}\int\limits_0^{x_D}\frac{\left(\frac{k_BT}{\hbar}x\right)^3}{e^x-1}\frac{k_BT}{\hbar}\mathrm{d}x\\&=\frac{3V\hbar}{2\pi^2v^3}\left(\frac{k_BT}{\hbar}\right)^4\int\limits_0^{x_D}\frac{x^3}{e^x-1}\mathrm{d}x=\frac{3V\hbar}{2\pi^2}\frac{k_BT}{\hbar}\left(\frac{k_BT}{v\hbar}\right)^3\int\limits_0^{x_D}\frac{x^3}{e^x-1}\mathrm{d}x\\&=\frac{3V}{2\pi^2}k_BT\left(\frac{k_BT}{v\hbar}\right)^3\int\limits_0^{x_D}\frac{x^3}{e^x-1}\mathrm{d}x=\frac{3\dfrac{N6\pi^2}{k^3}}{2\pi^2}k_BT\left(\frac{k_BT}{v\hbar}\right)^3\int\limits_0^{x_D}\frac{x^3}{e^x-1}\mathrm{d}x\\&=9Nk_BT\left(\frac{T}{T_D}\right)^3\int\limits_0^{x_D}\frac{x^3}{e^x-1}\mathrm{d}x\end{aligned}\tag{9.6.65}$$

where we have (we indicate here the two most common forms):

$$\boxed{T_D=\frac{v\hbar}{k_B}\left(6\pi^2\frac{N}{V}\right)^{1/3}=\frac{v_{\text{sound}}h}{2k_BL}\left(\frac{6N}{\pi}\right)^{1/3}}\tag{9.6.66}$$

We then have for the heat capacity:

$$\begin{aligned}C_V&=\left(\frac{\partial U}{\partial T}\right)_V=\frac{3V\hbar}{2\pi^2v^3}\frac{\partial}{\partial T}\int\limits_0^{\omega_D}\frac{\omega^3}{e^{\hbar\omega/k_BT}-1}\mathrm{d}\omega=\frac{3V\hbar}{2\pi^2v^3}\int\limits_0^{\omega_D}\frac{\partial}{\partial T}\frac{\omega^3}{e^{\hbar\omega/k_BT}-1}\mathrm{d}\omega\\&=\frac{3V\hbar^2}{2\pi^2v^3}\int\limits_0^{\omega_D}\left(-\frac{\omega^3}{\left(e^{\hbar\omega/k_BT}\right)^2}\cdot\left(-\frac{\hbar\omega}{k_BT^2e^{\hbar\omega/k_BT}}\right)\right)\mathrm{d}\omega=\frac{3V\hbar}{2\pi^2v^3}\frac{\hbar}{k_BT^2}\int\limits_0^{\omega_D}\frac{\omega^4e^{\hbar\omega/k_BT}}{\left(e^{\hbar\omega/k_BT}-1\right)^2}\mathrm{d}\omega\\&=\frac{3V\hbar^2}{2\pi^2v^3k_BT^2}\int\limits_0^{x_D}\frac{\left(\dfrac{k_BT}{\hbar}x\right)^4e^x}{(e^x-1)^2}\frac{k_BT}{\hbar}\mathrm{d}x=\frac{3V\hbar}{2\pi^2v^3T}\left(\frac{k_BT}{\hbar}\right)^4\int\limits_0^{x_D}\frac{x^4e^x}{(e^x-1)^2}\mathrm{d}x\\&=9Nk_B\left(\frac{T}{T_D}\right)^3\int\limits_0^{x_D}\frac{x^4e^x}{(e^x-1)^2}\mathrm{d}x\end{aligned}\tag{9.6.67}$$

If the absolute temperature is small, then we have:

$$C_{V,T\rightarrow 0}=9N_k\left(\frac{T}{T_D}\right)^3\int\limits_0^{+\infty}\frac{x^4e^x}{(e^x-1)^2}\mathrm{d}x\tag{9.6.68}$$

What is quite difficult to calculate. So we prefer rather use the following approach:

$$C_{V,T\rightarrow 0}=\left(\frac{\partial U}{\partial T}\right)_{V,T\rightarrow 0}=9Nk_B\frac{\partial}{\partial T}\left[T\left(\frac{T}{T_D}\right)^3\int\limits_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x\right]\tag{9.6.69}$$

And this last integral is known to us. Indeed, we will prove it in details below using the Riemann zeta function during our proof of the Stefan-Boltzmann constant (see page 3726):

$$\begin{aligned} C_{V,T\to 0} &= 9Nk_B\frac{\partial}{\partial T}\left[T\left(\frac{T}{T_D}\right)^3\int\limits_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x\right] \\ &= 9Nk_B\frac{\pi^2}{15T_D^3}\frac{\partial}{\partial T}T^4 = 3Nk_B\frac{\pi^2}{5T_D^3}4T^3 = \frac{12Nk_B\pi^2}{5}\left(\frac{T}{T_D}\right)^3 \end{aligned} \tag{9.6.70}$$

Therefore:

$$\boxed{C_{V,T\to 0} = \frac{12Nk_B\pi^2}{5}\left(\frac{T}{T_D}\right)^3} \tag{9.6.71}$$

and experimental measurement correspond quite well to that behaviour! The Debye model correctly predicts the low-temperature dependence of the heat capacity of solids, which is proportional to T^3. Similarly to the Einstein photoelectron model, it recovers the Dulong–Petit law at high temperatures. Due to simplifying assumptions, its accuracy suffers at intermediate temperatures. But the Debye model is correct at low temperatures whereas the Einstein model is not.

Even though the Debye model is not completely correct, it gives a good approximation for the low temperature heat capacity of insulating, crystalline solids where other contributions (such as highly mobile conduction electrons) are negligible. For metals, the electron contribution to the heat is proportional to T, which at low temperatures dominates the Debye T^3 result for lattice vibrations. In this case, the Debye model can only be said to approximate the lattice contribution to the specific heat. The following table lists Debye temperatures for several pure elements and sapphire:

Aluminium	428 [K]	Copper	343 [K]	Nickel	450 [K]	Silver	215 [K]
Beryllium	1440 [K]	Germanium	374 [K]	Platinum	240 [K]	Tantalum	240 [K]
Cadmium	209 [K]	Gold	170 [K]	Rubidium	56 [K]	Tin (white)	200 [K]
Caesium	38 [K]	Iron	470 [K]	Sapphire	1047 [K]	Titanium	420 [K]
Carbon	2230 [K]	Lead	105 [K]	Selenium	90 [K]	Tungsten	400 [K]
Chromium	630 [K]	Manganese	410 [K]	Silicium	645 [K]	Zinc	327 [K]

Table 9.25: **Some Debye temperatures**

To visualize the difference between the models, one would naturally plot the two on the same set of axes, but this is not immediately possible as both the Einstein model and the Debye model provide a functional form for the heat capacity. As models, they require scales to relate them to their real-world counterparts. One can see that the scale of the Einstein model is given by Θ (i.e. T_E in what will follow) and T_D for the Debye model. Because the two methods approach the problem from different directions and different geometries, Einstein and Debye scales are not the same, that is to say:

$$\frac{h\nu}{k_B}\neq T_D \tag{9.6.72}$$

which means that plotting them on the same set of axes makes no sense. They are two models of the same thing, but of different scales. If one defines the Einstein temperature as we did above:

$$T_E \overset{\text{def}}{=} \frac{h\nu}{k_B} \tag{9.6.73}$$

then it's obvious that:

$$T_E \neq T_D \tag{9.6.74}$$

and, to relate the two, we must seek the ratio

$$\frac{T_E}{T_D} \tag{9.6.75}$$

The Einstein solid is composed of single-frequency quantum harmonic oscillators, $\varepsilon = \hbar\omega = h\nu$. That frequency, if it indeed existed, would be related to the speed of sound in the solid. If one imagines the propagation of sound as a sequence of atoms hitting one another, then it becomes obvious that the frequency of oscillation must correspond to the minimum wavelength sustainable by the atomic lattice, λ_{min}, where:

$$\nu = \frac{\lambda\nu}{\lambda} = \frac{\lambda\nu\sqrt[3]{N}}{2L} = \frac{\lambda\nu}{2}\sqrt[3]{\frac{N}{V}} \tag{9.6.76}$$

which makes the Einstein temperature:

$$T_E = \frac{h\nu}{k_B} = \frac{h\lambda\nu}{2k}\sqrt[3]{\frac{N}{V}} = \frac{h\lambda\nu}{2k_B}\left(\frac{N}{V}\right)^{1/3} = \frac{hv}{2k_B}\left(\frac{N}{V}\right)^{1/3} \tag{9.6.77}$$

and the sought ratio is therefore:

$$\frac{T_\mathrm{E}}{T_\mathrm{D}} = \frac{\dfrac{hv}{2k_B}\left(\dfrac{N}{V}\right)^{1/3}}{\dfrac{v\hbar}{k_B}\left(6\pi^2\dfrac{N}{V}\right)^{1/3}} = \sqrt[3]{\frac{\pi}{6}} = 0.805995977\ldots \tag{9.6.78}$$

Using the ratio, both models can be plotted on the same graph:

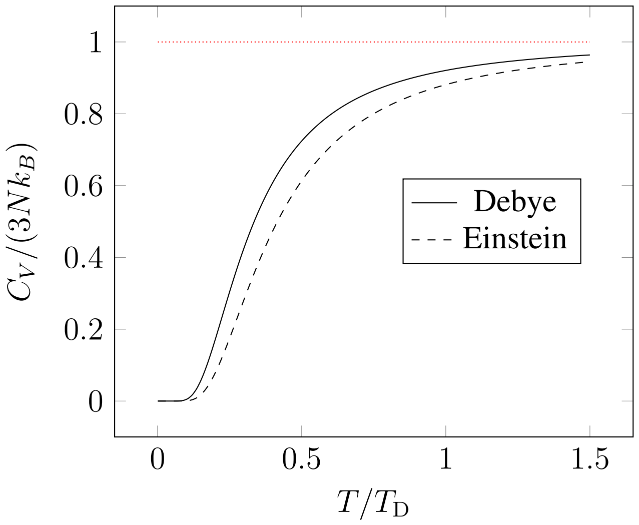


Figure 9.162: **Debye vs Einstein model**

This ratio is the cube root of the ratio of the volume of one octant of a 3-dimensional sphere to the volume of the cube that contains it, which is just the correction factor used by Debye when approximating the energy integral above. Alternatively, the ratio of the two temperatures can be seen to be the ratio of Einstein's single frequency at which all oscillators oscillate and Debye's maximum frequency. Einstein's single frequency can then be seen to be a mean of the frequencies available to the Debye model.

In thermodynamics, we must also always specify what is considered transformation as the ΔQ depends on the nature of the transformation. We distinguish in particular the heat capacity at constant volume (isochoric) and denoted:

$$C_V=\left(\frac{\delta Q}{\partial T}\right)_V \tag{9.6.79}$$

and heat capacity at constant pressure (isobaric) often used in chemistry and denoted:

$$C_P=\left(\frac{\delta Q}{\partial T}\right)_P \tag{9.6.80}$$

The difference between the specific heat at constant pressure C_P and constant volume specific heat C_V is obviously due to the work that must be provided to expand the body in the presence of external pressure. Both term also highlight a fundamental difference in the experimental setups measurement, that is to say physically different situations. In practice, to use the concept of heat capacity, we need to identify for our experience what C we must use depending on how the installation / machine will have been build.

Then it is quite intuitive that the specific heat at constant pressure is always strictly greater than the specific heat at constant volume $C_P>C_V$. We will also prove further below that we specifically for a perfect gas:

$$C_P-C_V=nR=Nk \tag{9.6.81}$$

If instead of considering the whole system, we report measurements to a unit of mass (which is much more useful in practice!), Then we define the "specific heat capacity" at constant volume (isochoric):

$$c_V=\frac{1}{M}\left(\frac{\delta Q}{\partial T}\right)_V \tag{9.6.82}$$

and the specific heat capacity at constant pressure (isobaric):

$$c_P=\frac{1}{M}\left(\frac{\delta Q}{\partial T}\right)_P \tag{9.6.83}$$

If instead of considering the whole system, we report the measurement to one mole of the considered medium (which is much more useful in chemistry!), We define the "molar heat capacity" at constant volume (isochoric):

$$c_V^M=\frac{1}{n}\left(\frac{\delta Q}{\partial T}\right)_V \tag{9.6.84}$$

and the molar heat capacity at constant pressure (isobaric):

$$c_P^M = \frac{1}{n}\left(\frac{\delta Q}{\partial T}\right)_P \tag{9.6.85}$$

where n is the number of moles of the system.

Here are some typical value for some gases at 293 [K] (i.e. 20 [°C]):

Gas	**Formula**	c_P^M **[J·mol⁻¹·K⁻¹]**
Air		29.1
Ammonia	NH_3	36.8
Argon	Ar	20.9
Nitrogen	N_2	29.1
Chlorine	Cl_2	33.8
Carbon dioxide	CO_2	36.8
Sulphur dioxid	SO_2	41.0
Ethine (acetylene)	C_2H_2	43.8
Hydrogen sulfide	H_2S	35.7
Helium	He	20.9
Hydrogen	H_2	28.9
Methan	CH_4	35.6
Neon	Ne	20.8
Oxygen	O_2	29.3

Table 9.26: **Some gases molar heat capacities**

So we have of course by extension, by going to the discrete case, the relation that is very useful in practice:

$$\boxed{\Delta Q = mc\Delta T} \tag{9.6.86}$$

where c is the specific polytropic heat capacity (and not the speed of light...!).

This is a very important relation in practice and whose everyday applications are huge because it allows in idealized cases to calculate the heat used or provided when a certain amount of material undergoes a change in temperature or calculate the final temperature of two bodies in contact.

Think about it when you take your shower or you heat a pot of water. You know then ΔT and the amount of water M used for your shower/bath or pan. This will give you the total energy used ΔQ and knowing the cost of energy in your city you quickly deduce the cost of a shower, a bath or a pot of boiling water!

Another nice application is to calculate the temperature increase (in an ideal case) of an object dropped from a certain height under the assumption that all its potential energy is converted into heat after touching the ground (the only problem being to find the value of the massic polytropic heat capacity in the tables...):

$$\Delta Q = mgh = mc_j\Delta T \tag{9.6.87}$$

where c_j is the massic polytropic energy capacity (it is simply c but given in joules per kilogram per kelvin rather than calories per kilogram per kelvin). So after rearrangement we have:

$$\boxed{\Delta T=\frac{mgh}{mc_j}} \tag{9.6.88}$$

The major case of the final equilibrium temperature of two bodies in contact is easy to obtain (if the system is completely isolated from the outside). Indeed, as the heat lost by one of the two bodies will be won by the other, we have by choosing properly ΔT for each of the two bodies so that ΔQ is the same sign:

$$c_1m_1(T_1-T_f)=c_2m_2(T_f-T_2) \tag{9.6.89}$$

Or after an elementary rearrangement:

$$\boxed{T_f=\frac{c_1m_1T_1+c_2m_2T_2}{c_1m_1+c_2m_2}} \tag{9.6.90}$$

✍**Example:**

A 0.3 [kg] steel bar has an initial temperature of $1,200$ [K] is immersed in a tank of water at 300 [K] (the tank is closed, isolated from the outside and full) containing 9 [kg] of water. Taking the specific polytropic heat capacity of water that is $4.2\,[\text{KJ}\cdot\text{kg}^{-1}\cdot\text{K}^{-1}]$ and that for steel $0.42\,[\text{KJ}\cdot\text{kg}^{-1}\cdot\text{K}^{-1}]$, the final equilibrium temperature (of the bar and water) is then:

$$T_f=\frac{4.2\cdot 10^3\cdot 9\cdot 300+0.42\cdot 10^3\cdot 0.3\cdot 1200}{4.2\cdot 10^3\cdot 9+0.42\cdot 10^3\cdot 0.3}=\frac{4.2\cdot 9\cdot 300+0.42\cdot 0.3\cdot 1200}{4.2\cdot 9+0.42\cdot 0.3}\cong 303\,[\text{K}] \tag{9.6.91}$$

Let us now consider the case where we have a system without exchange of mechanical work but only of heat by the following relation:

$$\Delta U=C\Delta T=C(T_2-T_1) \tag{9.6.92}$$

However, power is energy divided by time (see section Classical Mechanics page 3379). It comes therefore (take care not confuse the notation of power with that of pressure!):

$$P=\frac{C(T_2-T_1)}{t} \tag{9.6.93}$$

and if the heat capacity is given in the massic form at constant pressure:

$$P=\frac{mc_p(T_2-T_1)}{t}=\frac{m}{t}c_p(T_2-T_1) \tag{9.6.94}$$

Which already allows to calculate the power to be supplied to heat a quantity of material at a given temperature in a given time without state change otherwise we must we must take into account the latent heat.

The previous fraction can also be expressed as the flow rate of a fluid $\dot{V}$ $[\mathrm{m}^3\cdot\mathrm{s}^{-1}]$ multiplied by the fluid density:

$$\boxed{P=\dot{V}\rho c_p(T_2-T_1)} \tag{9.6.95}$$

which allows to know the power supplied by a water flow into a radiator at a certain temperature and leaving it with the same flow but with a different temperature. Those working with surfaces prefer to write this relation as follows:

$$\boxed{P=\dot{Q}=h_c S\Delta T} \tag{9.6.96}$$

which is often named "Newton's law of heat transfer by convection" or more simply "Newton's law of cooling" and where h_c is the "convection coefficient".

We will also find sometimes the prior-previous relation in the literature as follows:

$$E=mc_p(T_2-T_1)=\rho V c_p(T_2-T_1) \tag{9.6.97}$$

after having obviously multiplied both sides of the equality by the time.

✍**Example:**

A microprocessor surface of $25\,[\mathrm{mm}^2]$ is powered by a power source of 0.224 [W]. The ambient atmosphere is at 293 [K] $(20\,[^\circ\mathrm{C}])$ and the convection coefficient is given at the standard conditions of temperature and pressure as being equal to $h_c=150\,[\mathrm{W}\cdot\mathrm{m}^{-2}]$.

Considering that all the heat transfer takes place between the air and the microprocessor, the temperature of the latter can then be calculated as follows:

$$P=h_c S\Delta T=h_C S(T_2-T_1) \tag{9.6.98}$$

Therefore:

$$T_2=\frac{P}{h_C S}+T_1\cong\frac{0.225}{150\cdot 25\cdot 10^{-6}}+293=353\,[\mathrm{K}]=80\,[^\circ\mathrm{C}] \tag{9.6.99}$$

As we have know now that we have:

$$Q=m\cdot c\cdot(T_c-T_e) \tag{9.6.100}$$

where T_c is the core temperature of an object and T_e the temperature of its environment.

As we already have (we want to focus on the decrease of temperature hence the minus sign):

$$\frac{\mathrm{d}Q}{\mathrm{d}t}=-h_c\cdot S\cdot(T_c-T_e) \tag{9.6.101}$$

Injecting the first into to second one we get:

$$\frac{\mathrm{d}\left(m\cdot c\cdot(T_c-T_e)\right)}{\mathrm{d}t}=-h_c\cdot S\cdot(T_c-T_e) \tag{9.6.102}$$

Therefore after simplification and assuming T_e is constant (hence is derivative is zero):

$$\frac{\mathrm{d}T_c}{\mathrm{d}t}=-\frac{h_c S}{mc}(T_c-T_e) \tag{9.6.103}$$

Remarks

The relation above is often denoted in undergraduate textbooks:

$$T' \propto k\Delta T$$

And explained the by the analogy that a very hot (compared to its environment) drink does not stay hot for long. A tepid (compared to its environment) drink stays tepid for longer.

Rearranging:

$$\frac{1}{(T_c - T_e)}\mathrm{d}T_c = -\frac{h_c S}{mc}\mathrm{d}t \tag{9.6.104}$$

Taking primitives on both sides we get:

$$\ln(T_c - T_e) = -\frac{h_c S}{mc}t + c^{te} \tag{9.6.105}$$

Taking the exponential on both sides and rearranging we get:

$$T_c = e^{-\frac{h_c S}{mc}t + c^{te}} + T_e = e^{c^{te}}e^{-\frac{h_c S}{mc}t} + T_e := T_0 e^{-\frac{h_c S}{mc}t} + T_e \tag{9.6.106}$$

So finally we get the famous exponential time decrease of temperature:

$$\boxed{T_c = T_e + T_0 e^{-\frac{h_c S}{mc}t}} \tag{9.6.107}$$

In some transformations, we have a contribution or a heat withdrawal while the system temperature remains constant (typically in phase change transformations of a body). This comes from another phenomenon:

Definition (#9.6.464): The "enthalpy change of state" or "latent heat", denoted by L and is given in Joules per kilogram, corresponds to the quantity of heat required for a unit material quantity or a unit of mass of a body to changes its state. This is a very important value in practice to perform calculations.

So we of course by extension we have the very useful relation in practice:

$$\boxed{Q = mL} \tag{9.6.108}$$

which thus gives the quantity of heat required to change phase a certain quantity of mass m (the sign of Q is then negative then by convention). Conversely, if the amount of material returns to a lower energy level, the amount of latent heat will be given to the environment and not absorbed and the sign of Q will be positive!

Water has the following values for latent heat:

- The latent heat of vaporization of water is 540 calories per gram (changes 1 [g] water at 100 [°C] into 1 [g] steam at 100 [°C])
- The latent heat of fusion of water is 80 calories per gram (changes 1 [g] of ice at 0 [°C] into 1 [g] of water at 0 [°C])

The process also works in reverse. Above, heat was added to the substance, changing its phase from solid to liquid or liquid to gas. What if we cool the substance instead?

In this case, heat is released as the substance changes phase from gas to liquid and liquid to solid. It makes sense that the amount of heat required to change a gram of substance from liquid to gas is the same amount that is released when the substance changes from a gas back into a liquid. Because the values are the same, and the only difference is the direction of the process, we only use a single term for each phase change:

- "Latent heat of vaporization" or "enthalpy of vaporization": phase changes from liquid to gas OR gas to liquid;
- "Latent heat of fusion" or "enthalpy of fusion": phase changes from solid to liquid OR liquid to solid

The following picture shows what happens to 1 gram (1 ml) of water. The orange arrow on the top represents adding heat, from left to right, and the blue arrows represent releasing heat from right to left on the bottom:

Latent heat of vaporization—540 calories

Figure 9.163: **Water latent heat process (source: ?)**

We will prove later that at constant pressure the latter relation is then written more explicitly as follows:

$$\Delta H=\Delta Q=\int_{T_1}^{T_2} c_P \mathrm{d}T=\int_{T_1}^{T_2} C_P \mathrm{d}T \cong C_P \Delta T \qquad (9.6.109)$$

The enthalpy exchanged during the change of state results from the modification (rupture or establishment) of inter-atomic or intermolecular bonds. As we know are three main physical states for any pure substance: solid, liquid and gas. The links are stronger in solid form in the liquid state and these links are virtually absent in the gaseous state. There are, as we already know a fourth state obtained at very high temperature where the material is in the form of a plasma of ions and electrons (see section Continuum Mechanics page 3945).

We differentiate three main modes of heat transfer:

- "convection": fluid coming alternately from a hot body and a cold body (which is typical of the movements of the Earth's atmosphere).
- "radiation": a body at a given temperature emits electromagnetic radiation that can be absorbed by another body (the electromagnetic radiation being not necessarily in the visible spectrum part!).
- "conduction": energy transfer occurs from hot areas to cold areas by collision of the excited particles (hot zone) with neighbouring particles less excited and so on....

  That's why in space there is almost no heat transfer by conduction and by convection!

  To understand how density matters for heat transfer by conduction, consider that when baking bread in the oven, both air and metal plates are of the same temperature. However, while you can still put your hand into that oven (to take the bread out), you would be foolish trying to touch the metal plates...

  Or the analogy of a sauna: You often have around 100 degree Celsius in a sauna, and believe me - it is very nice (if you are into that kind of thing). But 100 degree water is boiling and lethal!

9.6.7.1 Newton's Law of Cooling

We have introduce earlier above the "Newton's law of cooling" that explains the rate at which an object/entity changes its temperature when it is exposed to radiation[24]. This change is almost proportional to the difference between the object's temperature and its surroundings temperature, given that this difference is quite small. Newton's law of cooling is included in virtually every introductory textbook on differential equations in the USA (but almost never in Europe).

We know that the formula of this law can be used to calculate how quickly a substance, at a particular temperature, would cool in a particular environment. Newton's law of cooling models the average temperature in an object by a simple ordinary differential equation as we will see it, while the heat equation is a partial differential equation that models the temperature as a function of both space and time. A series solution of the heat equation, in the case of a spherical body, shows that Newton's law gives an accurate approximation to the average temperature if the body is not too large and it conducts heat much faster than it gains heat from the surroundings (for the mathematical proof on a few dozens of pages see [207]). Finite element simulation confirms and extends the analysis.

---

[24] Newton did not originally state his law in the above form. Rather, using today's terms, Newton noted after some mathematical manipulation that the rate of temperature change of a body is proportional to the difference in temperatures between the body and its surroundings.

It also allows us to determine how the rate of cooling of an object depends not only on the temperature difference between the substance and the surrounding but also on the constant of the substance.

So let us introduce this law using an easier way than earlier above more adapted to college level students.

According to Newton's assumption we put:

$$\frac{\mathrm{d}T}{\mathrm{d}t} \propto (T-T_s) \Rightarrow \frac{\mathrm{d}T}{\mathrm{d}t} = -k\,(T-T_s) \tag{9.6.110}$$

where T is the temperature of the object, T_s the temperature of it's surroundings.

The negative sing on the right hand side implies that the rate of temperature change decreases.

Let T_f is the temperature at time t and T_0 is the temperature at the beginning.

Applying Integration on both sides:

$$\begin{aligned} \int_{T_f}^{T_0} \frac{\mathrm{d}T}{(T-T_s)} &= \int -k\mathrm{d}t \\ &\Rightarrow \ln\left(\frac{T_f-T_s}{T_0-T_s}\right) = -kt \\ &\Rightarrow \frac{T_f-T_s}{T_0-T_s} = e^{-kt} \\ &\Rightarrow T_f - T_s = (T_0-T_s)\,e^{-kt} \end{aligned} \tag{9.6.111}$$

Therefore:

$$\boxed{T_f = T_s + (T_0-T_s)\,e^{-kt}} \tag{9.6.112}$$

If we derive with rigour this relation from the heat equation (details available in [207]), then we see that the limitations of this relation are:

- The difference in temperatures between the surroundings and the object must be small
- The loss of heat should be via radiation only
- The temperature of the surroundings must remain constant during the cooling of the object

9.6.8 Internal Energy

In the section of Classical Mechanics, we have proved (second König's theorem) that the total energy of a body with respect to an external inertial frame R' to the center of mass was given by the sum of kinetic and potential energy compared to that same inertial frame, added to the kinetic energy and potential energy of that body relatively the reference frame of the center of mass R (barycentric repository).

$$E_{\text{tot}}=\left(E_{c,G/R}+E_{p,G/R}\right)+\left(E_{c,G/R'}+E_{p,G/R'}\right)=\left(E_{c,G/R}+E_{p,G/R}\right)+U \tag{9.6.113}$$

where U is the energy quantity or "internal energy" (also sometimes name "proper energy" or of the object itself relatively to its own reference frame.

In a more simplified form, the previous relation is traditionally written in thermodynamics for a closed isolated system:

$$E_{\text{tot}}=E_c+E_p+U \tag{9.6.114}$$

The first principle of thermodynamics is then written:

$$\boxed{Q+W=E_{\text{tot}}=E_c+E_p+U} \tag{9.6.115}$$

Therefore the total energy is the sum of the macroscopic mechanical energy (kinetic, potential or rotational) and microscopic (internal energy).

Generally in thermodynamic studied systems are generally at rest ($v_G=0$) with respect to the experimenter and therefore $\Delta E_c=0$. Similarly, we have generally a constant and isotropic potential field in the experimental room or area which implies equation $\Delta E_p=0$.

As a result of these simplifications the law of conservation of energy[25], or first principle of thermodynamics, is reduced as we have already mentioned to the internal energy as:

$$\boxed{Q+W=U} \tag{9.6.116}$$

or more rigorously:

$$\Delta Q+\Delta W=\Delta U \tag{9.6.117}$$

---

[25] It is strongly advice that the reader remembers the situation where this principle doesn't apply as seen during our study of Noether's theorem!

✍**Example:**

A piston contains 0.9 [kg] of air at a temperature of 300 [K] and a pressure of 1 [bar]. This air is compressed to a pressure of 6 [bar] to a temperature of 470 [K]. During the compression phase 20 [kJ] heat is exchanged between the external environment (heat conduction).

Using the fact that the internal massic energy of air is at 300 [K] given in the thermodynamic tables is equal to $u_1 = 214.07\,[\text{kJ}\cdot\text{kg}^{-1}]$ at 470 [K] as being equal to $u_2 = 337.32\,[\text{kJ}\cdot\text{kg}^{-1}]$, then we have the work done for the compression knowing that:

$$\Delta Q + \Delta W = \Delta U \tag{9.6.118}$$

that was equal to:

$$\Delta W = \Delta U - \Delta Q = m(u_2 - u_1) - \Delta Q = 0.9(337.32 - 214.07) - (-20) \cong 131\,[\text{kJ}] \tag{9.6.119}$$

Remark

The internal energy U is often given to a given additive constant, that is why some it is sometimes rightly named the "internal over-energy". As we have proved it in the section of Classical Mechanics, the total energy of a system is the sum of all elementary energies of it. Thus, the internal energy is an extensive quantity.

Some may ask what is exactly the internal massic energy?! It's quite easy in fact. For example when you touch something hot like a stove, you might think that there is heat in the stove but heat is only the energy being transfer. The energy in the stove is named "Internal Energy". It is made up of the energy of the fast moving atoms and the energy stored in the bonds that hold the atoms of the stove together. The hotter something is the more internal energy the object has. The diagram on the right shows an image of atoms held together with bonds, this is what a molecule of a solid or liquid would look like. When heat is transferred to the atoms they move very quickly, if enough heat is transferred then the bonds will break and the molecule will change state (melt or boil).

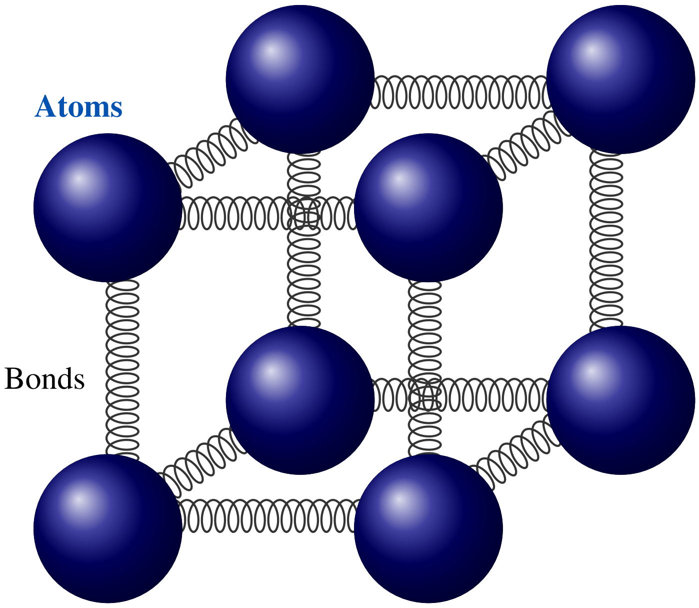

Figure 9.164: **Vibration bonds source of the internal energy in solid and liquids (author: Izaak Neutelings)**

This is why the internal energy is defined as: the energy associated with the random, disordered motion of molecules.

Typically the internal energy can be related to the following three internal energies with the corresponding energies proportions for the three common states of matter:

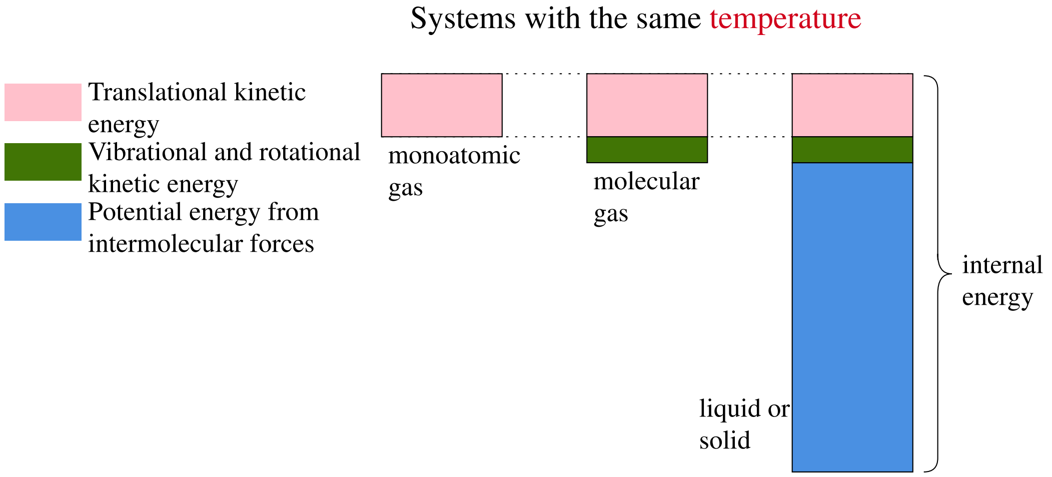

Figure 9.165: **Proportion of internal energy type by common state of matter**

Let us wow consider a system described by the thermodynamic state variables:

$$x_1, x_2, \ldots, x_n \tag{9.6.120}$$

In an elementary transformation $\mathrm{d}x_1, \mathrm{d}x_2, \ldots, \mathrm{d}x_n$ the elementary work $\mathrm{d}W$ (if we interested only to that form of energy) will be in the form (see section Differential and Integral Calculus page 1466) of an exact total differential:

$$\mathrm{d}W = A_1\mathrm{d}x_1 + A_2\mathrm{d}x_2 + \ldots + A_n\mathrm{d}x_n \tag{9.6.121}$$

if we have the following relation, proved in the section of Differential Calculus and Integral, which is satisfied (which are the coefficients of the $\mathrm{d}x_i$ above):

$$\frac{\partial A_i}{\partial x_j}=\frac{\partial A_j}{x_i} \tag{9.6.122}$$

Otherwise, if this relation is not satisfied, which would imply:

$$\frac{\partial A_i}{\partial x_j}\neq\frac{\partial A_j}{x_i} \tag{9.6.123}$$

whereas in the latter case, we have an inexact total differential (the differential depends of the path!) which would bring us to write:

$$\delta A=A_1\mathrm{d}x_1+A_2\mathrm{d}x_2+\ldots+A_n\mathrm{d}x_n \tag{9.6.124}$$

Since the mechanical work W is in one way or another a force over a distance, we have already proved in the section of Classical Mechanics that it depends on the path travelled and not only the starting and final point.

In the same transformation, the quantity of heat $\mathrm{d}Q$ can be put in a similar form:

$$\mathrm{d}Q=B_1\mathrm{d}x_1+B_2\mathrm{d}x_2+\ldots+B_n\mathrm{d}x_n \tag{9.6.125}$$

if again the following relation holds for the state variables:

$$\frac{\partial B_i}{\partial x_j}=\frac{\partial B_j}{x_i} \tag{9.6.126}$$

or otherwise:

$$\delta Q=B_1\mathrm{d}x_1+B_2\mathrm{d}x_2+\ldots+B_n\mathrm{d}x_n \tag{9.6.127}$$

The characteristic quantities of a transformation of the system but whose value depends not only on the initial and final states, but also t the path followed are named "transfer quantities".

Let us recall that knowing what has already been studied in the section of Differential and Integral Calculus then we have for a thermodynamic cycle in an isolated system:

$$\boxed{\Delta U=\oint\mathrm{d}U=0\qquad\Delta Q=\oint\delta Q=0\qquad\Delta W=\oint\delta W\neq 0} \tag{9.6.128}$$

and that is the fact that the internal energy is an exact total differential which logically requires that the heat Q is an inaccurate total differential by the property of linearity of integral (otherwise it would not cancel by summing the variations of the W a closed cycle). Indeed, according to the first law of thermodynamics, if the energy is conservative for a closed isolated system then we have for the internal energy (in discrete form):

$$\Delta U=0 \tag{9.6.129}$$

This means that regardless of the transformation, the variations of work and heat are given within this conservative system by (in discrete form):

$$\boxed{\Delta Q+\Delta W=0} \tag{9.6.130}$$

or more technically:

$$\oint \mathrm{d}U=\oint(\delta U+\delta W)=\underbrace{\oint \delta Q}_{\neq 0}+\underbrace{\oint \delta Q}_{\neq 0}=0\Rightarrow\oint \delta Q=-\oint \delta W \qquad (9.6.131)$$

Therefore regardless of the ways in which transformations occur inside the system, the final and initial state are identical in terms of energy in an isolated system. This assumes that the thermodynamic transformations are independent of the manner in which the phenomena take place inside the system. The term ΔU is then an exact total differential (see section Differential and Integral Calculus page 1466) that we will write $\mathrm{d}U$.

9.6.8.1 Work (energy) of Mechanical Forces

Mechanical work is the amount of energy transferred by a force. Like energy, it is a scalar quantity, with SI units of joules. Heat conduction is not considered to be a form of work, since there is no macroscopically measurable force, only microscopic forces occurring in atomic collisions. In the 11830s (holocene calendar), French mathematician Gaspard-Gustave Coriolis coined the term work for the product of force and distance.

Let us recall now that we have seen in the section of Classical Mechanics that, by definition, the work W is given by a force over a distance (whatever the origin of this force: mechanical, radiant, nuclear, etc.). It follows therefore a quite important relation in thermodynamics:

$$\boxed{\mathrm{d}W=\vec{F}\circ\mathrm{d}\vec{l}=PS\mathrm{d}x=P\mathrm{d}V} \qquad (9.6.132)$$

which expresses, at constant pressure (isobaric), the variation of the energy due to the work of the external pressure forces on a system (typically a thermodynamic gas..) whose volume has varied (without being restricted by rigid boundary!).

Obviously, if the volume variation is zero or there is no pressure... the change in energy due to work pressure forces will be zero at equilibrium...

At equilibrium, the pressure P is taken as the considered system (internal pressure) or that of the surrounding atmosphere as anyway the pressure will be equal if the system is in contact with the atmosphere (otherwise there would be no equilibrium at the opposite of what we have just assumed at the beginning of this paragraph...).

Similarly, the change in volume is taken as being either that of the considered system (proper volume) or the variation of the surrounding atmosphere since in any case the volume change will be the same for both!

Moreover, we see that the path is appears explicitly in the previous expression of the work and therefore that it is a quantity that depends on the path travelled (see section Differential and Integral Calculus page 1583). This implies that we must write δW instead of equation $\mathrm{d}W$. There are of course many other ways of expressing the work, but by it's own definition, it will always be an inexact differential.

This result has a direct implication on the expression of heat change for which the virial theorem (see section Continuum Mechanics page 3897): that it is given by the thermal agitation.

It should be recalled that this agitation is given by the average kinetic energy and kinetic energy exist by applying a force over a distance for each particle. Thus heat is also an inexact differential δQ!

Finally, we have in the case of a fluid (liquid or gas) having an internal polytropic energy change:

$$\boxed{\mathrm{d}U=\delta Q+\delta W} \tag{9.6.133}$$

During its evolution, the volume V of the system may vary. If we consider an infinitesimal change during which the volume varies of $\mathrm{d}V$ and if we denote by P_e the external pressure on the system, we will write in a more general context (the negative sign in front of the pressure is a convention!):

$$\delta W=-P_e\mathrm{d}V+\mathrm{d}T \tag{9.6.134}$$

where $-P_e\mathrm{d}V$ is the work named "outside delivery" (if $\mathrm{d}V>0$, the increase of the volume of the system expresses the supply of work to the external environment, which is what the sign $-$ explains indicating that the internal energy of the system decreases) and where $\mathrm{d}T$ (not to be confused with temperature variation!!!) is another form of energy (if the system is reactive to the chemical level for example, it can provide a potential chemical energy too).

Except in special systems (batteries, accumulators, ...) the only energy exchanged is the work of the pressure forces so that we keep only:

$$\delta W=-P_e\mathrm{d}V \tag{9.6.135}$$

and then we can write $\mathrm{d}W$ at leisure instead of using the inexact differential δW since this work is dependent only of on state variable (the notation $\mathrm{d}W$ being often used in physics in this case)!

In addition, most systems are studied by hypothesis, at equilibrium, at the same internal pressure as the external pressure (ambient atmosphere). This allows us in this case to write:

$$P_e=P \tag{9.6.136}$$

where P is the pressure inside and outside of the system (the system is then said "isobaric" as we already know it and rarely "monobaric").

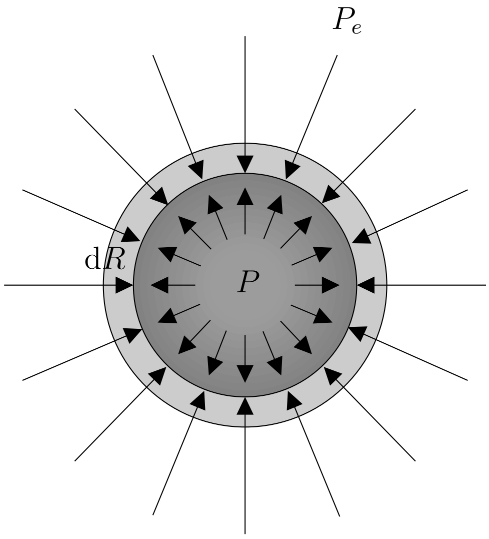

Figure 9.166: **Example of a sphere at pressure equilibrium with the environment**

Therefore, we have in this particular case:

$$\delta W = -P\mathrm{d}V \qquad \Delta W = -\int_1^2 P\mathrm{d}V \tag{9.6.137}$$

The heat quantity Q_V into play in an isochoric transformation (at constant volume) then reduces obviously the change in internal energy such that (caution with the traditional notation Q_V that can makes us forget that we are dealing with a heat variation !):

$$\delta Q := Q_V = U_2 - U_1 \tag{9.6.138}$$

If we consider a system evolving from a state 1 to a state 2 in a surrounding isobaric atmosphere (constant pressure) and therefore that its internal pressure is in equilibrium with the atmosphere, then we have the "mechanical forces at constant pressure" relation:

$$\boxed{\Delta W = -\int_1^2 P\mathrm{d}V = -P(V_2 - V_1)} \tag{9.6.139}$$

Or if the system evolves from a state 1 to a state 2 in an isotherm environment, then we have the "mechanical forces at constant temperature" relation for a perfect gas:

$$\boxed{\Delta W = -\int_1^2 P\mathrm{d}V = -\int_1^2 \left(\frac{nRT}{V}\right)\mathrm{d}V = -nRT\int_1^2 \frac{\mathrm{d}V}{V} = -nRT\ln\left(\frac{V_2}{V_1}\right)} \tag{9.6.140}$$

If we want to produce a reasonable amount of work it seems a priori that the volume will have to reach unrealistic dimensions. So this is why we build thermal machines with a cyclic return.

OK... with what we have seen so far we can already make the following summary:

Process	What is constant	The first law predicts
Isothermal	$T =$ constant	$\Delta T = 0$ makes $\Delta U = 0$, so $\Delta Q = \Delta W$
Isobaric	$P =$ constant	$\Delta P = 0$ makes $\Delta Q = \Delta U + W = \Delta U + P\Delta V$
Isochoric	$V =$ constant	$\Delta V = 0$ makes $\Delta W = 0$ so $\Delta Q = \Delta U$
Adiabatic	Q =constant	$\Delta Q = 0$ makes $\Delta U = -\Delta W$

Table 9.27: **Summary of basic thermodynamics processes**

9.6.8.2 Enthalpy

Let us consider the isobaric case very common in chemistry labs since the beakers are open to the ambient atmosphere. If we consider such a situation, then we have for the variation of internal energy:

$$U_2 - U_1 = \Delta Q - P(V_2 - V_1) \rightarrow \Delta Q = U_2 - U_1 + P(V_2 - V_1) = (U_2 + PV_2) - (U_1 + PV_1) \tag{9.6.141}$$

so where the pressure P and the volume V are the internal state variables to the studied system! It is important to notice again that if the change in heat ΔQ is zero and that the internal volume increases the internal energy U variation is then negative, which will be interpreted by the experimenter as an energy taken to the external system and so it is common to speak of "loss" or "endothermic reaction"!

The heat quantity Q_P into play in an isobaric transformation (the index of Q_P is indicated in this purpose... can makes us forget that we are dealing with a variation of heat) is equal to the variation of two terms in identical form:

$$\Delta Q := Q_P = (U_2 + PV_2) - (U_1 + PV_1) = H_2 - H_1 = \Delta H \tag{9.6.142}$$

where we therefore define a new convenient function of state, named "enthalpy H" (extensive quantity) in an isobaric transformation as given by:

$$\boxed{H = U + PV = U + nRT} \tag{9.6.143}$$

where n is the number of moles internal to the ideal gas undergoing the volume change! We see further that if the surrounding pressure is zero, the enthalpy is equal to the internal energy. The fact that there are external pressures force (or internal) adds an energy to the system which therefore defines the concept of enthalpy!

The prior previous relation expresses the fact that when a system evolves at constant pressure, the heat received (or exchanged by the system with the external environment) is equal to the enthalpy change.

It also comes with this new definition a new possible writing of to the heat capacity at constant pressure frequently used in chemistry:

$$C_P = \left(\frac{\delta Q}{\partial T}\right)_P = \frac{\partial H}{T} \tag{9.6.144}$$

So get the very important relation in practice that we had specified earlier above for the latent heat (enthalpy of state change):

$$\Delta H = m\int_{T_1}^{T_2} c_P \mathrm{d}T = \int_{T_1}^{T_2} C_P \mathrm{d}T \cong C_P \Delta T \tag{9.6.145}$$

where we must not forget that strictly speaking the fixed pressure heat capacity is not constant, it is quite often considered in practice as constant for a given temperature range.

More explicitly, we have also for the prior previous relation using the ideal gas law:

$$H = U + PV = \frac{\mathrm{df}}{2}nRT + nRT = \frac{\mathrm{df}+2}{2}nRT \tag{9.6.146}$$

where for recall (see section Continuum Mechanics page 3897) the number of degrees of freedom df for a perfect monoatomic gas is equal to 3. The last term of this relation is obviously not valid for fluids!

Sometimes we obviously also write the definition of enthalpy in the form of a variation such that:

$$\Delta H = \Delta U + P\Delta V = nR\Delta T \tag{9.6.147}$$

in the particular case of application to the field of validity of the ideal gas (see section Continuum Mechanics page 3903) regarding to the last term.

It is important to remember that the term PV in the previous relations represents the work of the pressure forces from the surrounding atmosphere on the system or by equivalence, respectively of the system on the surrounding atmosphere that surrounds it. But the variable n is always the number of moles of an ideal gas of the system studied and not the surrounding atmosphere.

The enthalpy is a concept used extensively in thermal chemistry (see section Thermochemistry page 6249) and we will use it constantly in its study.

In practice it is difficult (if not impossible) to know the internal energy. We then calculate rather the relation relatively to one mole (n being then equal to 1) of a perfect gas:

$$H-U=RT=PV \tag{9.6.148}$$

That is a strictly positive value giving the energy (or rather the surplus of energy) available in the ideal gas because of the surrounding pressure (there is only to put the pressure as being equal to zero to see it!).

✍**Example:**

Let us take a molar unit volume of ideal gas at standard temperature and pressure (whatever that perfect gas, the molar volume under these conditions will always 24 litres according to the ideal gas law!).

The work of the pressure forces that were necessary to bring this ideal gas to the above conditions is then:

$$H-U=PV\cong 1.015\cdot 10^5\frac{24}{1000}=2,436\,[\text{J}] \tag{9.6.149}$$

or:

$$H-U=RT\cong 293.15\cdot 8.31=2,436\,[\text{J}] \tag{9.6.150}$$

which is energy in the form of mechanical forces of pressure that we could recover from a molar volume of air in comparison to the vacuum state.

The internal energy into the form of heat and mechanical work that we could recover in theory (the problem is how to...) of the molar volume is given for a monoatomic gas (see further below for the detailed proof), by :

$$H=Q=c_P^M RT=U+PV=\frac{\text{df}+2}{2}RT=\frac{5}{2}RT\cong 6\,[\text{kJ}] \tag{9.6.151}$$

and we could also calculate the internal energy of the electrons binding, and that of the nuclei of atoms... and the equivalence mass and energy, but we would go out of common industrial case...

For water, we can only use the first relation, because the second one is valid only for ideal gases, the molar volume is $1,000$ times smaller, we can only extract of it an energy $1,000$ times smaller (about 2 [J]). This is why in the case of fluids, we consider that there is no difference between the enthalpy and internal energy.

Let us now see other theoretical implications of some previously seen items that will be very useful both in acoustic (see section Music Mathematics page 8195) or in Continuum Mechanics (see section of the same name page 3734).

9.6.8.3 Laplace's law

We have proved in the section of Continuum Mechanics with the virial theorem (see page 3897) that the internal energy (kinetic energy) of a perfect monoatomic gas was given by:

$$U=\frac{3}{2}kNT \tag{9.6.152}$$

where we took the notation of the section of Continuum Mechanics (an uppercase N instead of an uppercase n).

Therefore we have:

$$\mathrm{d}U=\frac{3}{2}kN\mathrm{d}T \tag{9.6.153}$$

If the transformation process is at constant volume, we will assume that there is no mechanical work (force over a distance) provided (inelastic collisions on the walls) and then:

$$\mathrm{d}U=\delta Q+\delta W=\delta Q_V=\frac{3}{2}kN\mathrm{d}T \tag{9.6.154}$$

therefore where $\mathrm{d}W$ is zero!

It comes then the possibility to calculate the heat capacity at constant volume:

$$\boxed{C_V=\left(\frac{\delta Q}{\mathrm{d}T}\right)_V=\frac{3}{2}kN=\frac{3}{2}\frac{R}{N_{\text{A}}}N=\frac{3}{2}R\frac{N}{N_{\text{A}}}} \tag{9.6.155}$$

where we then observed, that for an ideal gas, the volumetric heat capacity is independent of the volume !! We have verbatim for a mole:

$$C_V^M=\frac{C_V}{\dfrac{N}{N_{\text{A}}}}=\frac{C_V}{N}N_{\text{A}}=\frac{3}{2}R \tag{9.6.156}$$

so that we can write for an ideal monoatomic gas at constant volume the internal energy:

$$U=\frac{3}{2}R\frac{N}{N_{\text{A}}}T=C_VT \tag{9.6.157}$$

which allows to know in practice, and from table, the internal energy variation of a gas depending on its temperature variation since:

$$\Delta U=C_V\Delta T \tag{9.6.158}$$

which of course corresponds to a supply work or absorbed work. Under its differential form we name it the "first Joule's law" (internal energy of an ideal gas depends only on the temperature)

$$\boxed{\mathrm{d}U=nC_v\mathrm{d}T} \tag{9.6.159}$$

An interesting case of the prior previous relation is to remember that as we are at constant volume we have then:

$$\left.\begin{array}{l}P_1V_1=nRT_1\\P_2V_2=nRT_2\end{array}\right\}\frac{P_1}{T_1}=\frac{P_2}{T_2}\Rightarrow T_2=\frac{P_2}{P_1}T_1 \tag{9.6.160}$$

This allows us to write:

$$\Delta U=C_V\Delta T=C_V(T_2-T_1)=C_V\left(\frac{P_2-P_1}{P_1}\right)T_1 \tag{9.6.161}$$

With the important part:

$$\boxed{\Delta U=C_V(T_2-T_1)=C_V\left(\frac{P_2-P_1}{P_1}\right)T_1} \tag{9.6.162}$$

So if there is decompression (gas expansion), the latter relation is negative. In this case the gas loses heat to the environment this is why when a container of a gas release a gas it cools down!

If the process takes place at constant pressure (constant kinetic energy of the gas atoms) then we have (see virial theorem in the section of Continuum Mechanics page 3897):

$$\delta W=-P\mathrm{d}V=-kN\mathrm{d}T \tag{9.6.163}$$

(the collisions that push the wall of the volume make the system loose hence the sign "$-$").

Therefore:

$$\mathrm{d}U=\delta Q_P+\delta W\Rightarrow\delta Q_P=\mathrm{d}U-\delta W=\frac{3}{2}kN\mathrm{d}T+kN\mathrm{d}T=\frac{5}{2}kN\mathrm{d}T \tag{9.6.164}$$

Thus we can also calculate the heat capacity at constant pressure:

$$\boxed{C_P=\left(\frac{\delta Q}{t}\right)_P=\frac{5}{2}kN=\frac{5}{2}kN=\frac{5}{2}\frac{R}{N_\mathrm{A}}N=\frac{5}{2}R\frac{N}{N_\mathrm{A}}} \tag{9.6.165}$$

where can therefore observed, for an ideal gas, that the heat capacity at constant pressure is also independent of the pressure !! We have verbatim for a mole:

$$c_P^M=\frac{C_P}{\dfrac{N}{N_\mathrm{A}}}=\frac{C_P}{N}N_\mathrm{A}=\frac{5}{2}R \tag{9.6.166}$$

Of the two boxed previous results we get for an ideal mono-atomic gas the "heat capacity ratio" or also named "adiabatic index" or "ratio of specific heats" or "Poisson constant":

$$\boxed{\gamma=\frac{C_P}{C_V}=\frac{5}{3}} \tag{9.6.167}$$

with the "Mayer relation":

$$\boxed{C_P-C_V=\frac{5}{2}R\frac{N}{N_\mathrm{A}}-\frac{3}{2}R\frac{N}{N_\mathrm{A}}=nR} \tag{9.6.168}$$

which gives us the same time as R is positive:

$$C_P > C_V \tag{9.6.169}$$

We get also a relation that will be useful later:

$$C_P = C_V + nR = \frac{C_P}{\gamma} + nR \Rightarrow C_P\left(1 - \frac{1}{\gamma}\right) = nR \Rightarrow = nR\frac{\gamma}{\gamma - 1} \tag{9.6.170}$$

If the ideal gas is diatomic, there are 5 degrees of freedom (3 for the position of the first atom, 3 for the position of the second one, -1 for the constraint that the distance between them is fixed) and we then have:

$$\mathrm{d}U \cong \frac{5}{2}kN\mathrm{d}T \tag{9.6.171}$$

By doing the same developments, we get (value that will use in the section Music Mathematics but which is useful in many other fields of physics):

$$\boxed{\gamma = \frac{C_P}{C_V} = \frac{7}{5}} \tag{9.6.172}$$

When an isolated system of ideal gas undergoes an adiabatic transformation at constant pressure, the internal energy change in the system will be drawn by the variation of internal work. Which traditionally is written by a negative sign such that(using the result above):

$$\mathrm{d}U = -\delta W = -P\mathrm{d}V = C_v\mathrm{d}T \tag{9.6.173}$$

Remark

Warning!!! Let us recall that the choice of the sign for the work W is only a sign convention !! Thus, in this case study it is the tradition to put a "$-$" instead of a "$+$". But this does not change the results that will follow !!!

Hence:

$$P\mathrm{d}V + C_V\mathrm{d}T = 0 \tag{9.6.174}$$

Let us now take the ideal gas equation $PV = nRT$ (without collisions) and differentiate. We get:

$$P\mathrm{d}V + V\mathrm{d}P = Nk\mathrm{d}T \Rightarrow \mathrm{d}T = \frac{P\mathrm{d}V + V\mathrm{d}P}{Nk} \tag{9.6.175}$$

Therefore by eliminating $\mathrm{d}T$ between the last two relations, we get:

$$P\mathrm{d}V + C_V\frac{P\mathrm{d}V + V\mathrm{d}P}{Nk} = 0 \tag{9.6.176}$$

Thus after simplification and rearrangement of the terms:

$$(Nk + C_V)P\mathrm{d}V + C_V V\mathrm{d}P = 0 \tag{9.6.177}$$

What reported to moles quantities is written (as customary for chemists)

$$(R + c_V^M)p\mathrm{d}V + c_V^M V\mathrm{d}p = 0 \tag{9.6.178}$$

anyway ... by remembering that:

$$C_P - C_V = nR = Nk \tag{9.6.179}$$

We have:

$$C_P P\mathrm{d}V + C_V V\mathrm{d}P = 0 \tag{9.6.180}$$

Using the definition of the Laplace coefficient, also named "adiabatic coefficient" already met earlier:

$$\gamma = \frac{C_P}{C_V} \tag{9.6.181}$$

we get the expression:

$$\gamma P\mathrm{d}V + V\mathrm{d}P = 0 \tag{9.6.182}$$

Rearranging we get:

$$\gamma\frac{\mathrm{d}V}{V} + \frac{\mathrm{d}P}{P} = 0 \tag{9.6.183}$$

We get by integration:

$$\gamma\int\frac{\mathrm{d}V}{V} + \int\frac{\mathrm{d}P}{P} = 0 \tag{9.6.184}$$

therefore:

$$\ln(P) + \gamma\ln(V) = c^{te} \tag{9.6.185}$$

which is equivalent using the properties of logarithms to:

$$\boxed{PV^{\gamma} = c^{te}} \tag{9.6.186}$$

This is the famous "Laplace's thermodynamcis law" or "polytropic gas equation" which gives the relation between pressure and volume in an adiabatic transformation of a gas (which does not mean that the temperature is constant for recall but only that exchange of heat with the outside system is zero or at least negligible!). We will reuse besides this relation in the section of Marine & Weather Engineering.

Thus, we also have the following information that may be useful in the industry:

$$\begin{aligned} W &= \int_{V_1}^{V_2} P\mathrm{d}V = c^{te}\int_{V_1}^{V_2} V^{-\gamma}\mathrm{d}V = c^{te}\frac{V^{1-\gamma}\Big|_{V_1}^{V_2}}{1-\gamma} = c^{te}\frac{V_2^{1-\gamma} - V_1^{1-\gamma}}{1-\gamma} = \frac{c^{te}V_2^{-\gamma}V_2 - c^{te}V_1^{-\gamma}V_1}{1-\gamma} \\ &= \frac{P_2V_2 - P_1V_1}{1-\gamma} = \frac{Nk(T_2 - T_1)}{1-\gamma} \end{aligned} \tag{9.6.187}$$

As well as:

$$\frac{P_2}{P_1}=\left(\frac{V_1}{V_2}\right)^{\gamma}=\left(\frac{\dfrac{N_1kT_1}{P_1}}{\dfrac{N_2kT_2}{P_2}}\right)^{\gamma}\underset{N_1=N_2}{=}\left(\frac{T_1P_2}{T_2P_1}\right)^{\gamma}\Rightarrow\frac{T_1}{T_2}=\left(\frac{P_2P_1^{\gamma}}{P_1P_2^{\gamma}}\right)^{1/\gamma}=\left(\frac{P_1^{\gamma-1}}{P_2^{\gamma-1}}\right)^{1/\gamma}=\left(\frac{P_1}{P_2}\right)^{\gamma-1/\gamma} \tag{9.6.188}$$

verbatim:

$$\frac{T_1}{T_2}=\left(\frac{P_1}{P_2}\right)^{\gamma-1/\gamma}=\left(\left(\frac{V_2}{V_1}\right)^{\gamma}\right)^{\gamma-1/\gamma}=\left(\frac{V_2}{V_1}\right)^{\gamma-1} \tag{9.6.189}$$

So in the end we have the very useful relations in practice for the polytropic case:

$$\boxed{\frac{T_1}{T_2}=\left(\frac{P_1}{P_2}\right)^{\gamma-1/\gamma}=\left(\frac{V_2}{V_1}\right)^{\gamma-1}} \tag{9.6.190}$$

The problem in practice... is to have in the value of the adiabatic coefficient ...

OK so far we can make the following small summary hoping it helps:

	ΔQ	ΔW	ΔU	ΔH
Isothermal	$\Delta Q=nRT\ln\left(\frac{V_f}{V_i}\right)$ $=nRT\ln\left(\frac{P_f}{P_i}\right)$	$-\Delta Q$	0	0
Isochoric	$\Delta Q=nC_v\Delta T=\Delta U$	0	$\Delta U=nC_v\Delta T$	$\Delta H=nC_P\Delta T$
Isobaric	$\Delta Q=nC_P\Delta T=\Delta H$	$\Delta W=-P\Delta V$ $=-nR\Delta T$	$\Delta U=nC_v\Delta T$	$\Delta H=nC_P\Delta T$
Adiabatic	0	$\Delta W=nC_V\Delta T$	$\Delta U=nC_v\Delta T$	$\Delta H=nC_P\Delta T$

Table 9.28: **Main ideal gas processes (reversible processes)**

We will use the polytropic gas equation above for an adiabatic expansion to calculate the change ΔP in pressure when we change the volume of the gas in a cylinder by an amount ΔV. Before we compress we have:

$$PV^{\gamma}=P_0V_0^{\gamma} \tag{9.6.191}$$

where P_0 and V_0 are our original pressure and volume.

After the expansion, V goes to $V_0+\Delta V$ and P goes to $P_0+\Delta P$, where we know that ΔP is negative for an expansion. Thus after expansion we have:

$$PV^{\gamma}=(P_0+\Delta P)(V_0+\Delta V)^{\gamma} \tag{9.6.192}$$

With $PV^{\gamma}=P_0V_0^{\gamma}=c^{te}$, we get:

$$P_0V_0^{\gamma}=(P_0+\Delta P)(V_0+\Delta V)^{\gamma} \tag{9.6.193}$$

We can use the fact that ΔV is very small compared to V_0 to get:

$$(V_0+\Delta V)^{\gamma}=\left[V_0\left(1+\frac{\Delta V}{V_0}\right)\right]=V_0^{\gamma}\left(1+\frac{\Delta V}{V_0}\right)^{\gamma} \tag{9.6.194}$$

Using the binomial series (see section Calculus page 1364):

$$(1+\alpha)^{\gamma}\cong 1+\gamma\alpha \tag{9.6.195}$$

for a small α, we have:

$$\left(1+\frac{\Delta V}{V_0}\right)^{\gamma}\cong 1+\gamma\frac{\Delta V}{V_0} \tag{9.6.196}$$

Therefore:

$$P_0V_0^{\gamma}=(P_0+\Delta P)(V_0+\Delta V)^{\gamma}=P_0\left(1+\frac{\Delta P}{P_0}\right)V_0^{\gamma}\left(1+\gamma\frac{\Delta V}{V_0}\right) \tag{9.6.197}$$

Multiplying this out gives:

$$P_0V_0^{\gamma}=P_0V_0^{\gamma}\left(1+\frac{\Delta P}{P_0}+\frac{\gamma\Delta V}{V_0}+\frac{\gamma}{P_0V_0}\Delta P\Delta V\right) \tag{9.6.198}$$

The factors $P_0V_0^{\gamma}$ cancel, and we can neglect the second order term $\Delta P\Delta V$, giving:

$$1=1+\frac{\Delta P}{P_0}+\frac{\gamma\Delta V}{V_0} \tag{9.6.199}$$

After cancelling the 1's and multiplying through by P_0 we get for the pressure change ΔP:

$$\boxed{\Delta P=-\gamma P_0\left(\frac{\Delta V}{V_0}\right)} \tag{9.6.200}$$

9.6.8.4 Saint-Venant Thermodynamic Equation

There are several equations that bear the name of "Saint-Venant equation" in physics ... one that concerns us here is very useful in the field of aero-dynamics and is more "thermodynamics" oriented that the equation of the same name in the field of incompressible fluid mechanics.

Let us see what it is!

We will consider a compressible gas or fluid always using the first law of thermodynamics but by highlighting from the internal energy explicitly three macroscopic energies commonly used in the field of Continuum Mechanics:

$$\Delta U=\Delta E_c+\Delta E_p+\Delta H=\Delta Q+\Delta W \tag{9.6.201}$$

To introduce the Saint-Venant equation for thermodynamics as simple as possible, we will consider only the cases where the changes in potential energy, heat exchanges and work are negligible or zero (which is a strong hypothesis but not non-existent in some practical cases). Then we have:

$$\Delta E_p+\Delta H=\frac{1}{2}m(v_2^2-v_1^2)+(H_2-H_1)=0 \tag{9.6.202}$$

which seems sometimes be named "Thomson equation" or "Zeuner formula" (we give names to anything sometimes...).

Which brings us to write:

$$\frac{1}{2}mv^2+H=c^{te} \tag{9.6.203}$$

Now we have prove earlier above that:

$$\Delta H\cong C_P\Delta T=mc_P\Delta T=nR\frac{\gamma}{\gamma-1}\Delta T=nR\frac{\gamma}{\gamma-1}\Delta\left(\frac{PV}{nR}\right)=\frac{\gamma}{\gamma-1}\Delta(PV) \tag{9.6.204}$$

Often the latter relation is expressed in massic form such that:

$$\frac{\Delta H}{n}=\Delta h\cong\frac{\gamma}{\gamma-1}\Delta\left(P\frac{V}{m}\right)=\frac{\gamma}{\gamma-1}\Delta\left(\frac{P}{\rho}\right) \tag{9.6.205}$$

or written differently:

$$h=\frac{\gamma}{\gamma-1}\frac{P}{\rho} \tag{9.6.206}$$

It comes therefore the "Saint-Venant equation for thermodynamics":

$$\boxed{\frac{1}{2}v^2+h=\frac{1}{2}v^2+\frac{\gamma}{\gamma-1}\frac{P}{\rho}=c^{te}} \tag{9.6.207}$$

If we rewrite this relation between two points but we choose one of the two points has zero speed (whatever which one) we can always bring us back to a relation of the form:

$$\frac{\gamma}{\gamma-1}\frac{P_{\text{eg}}}{\rho_{\text{eg}}}=\frac{\gamma}{\gamma-1}\frac{P}{\rho}+\frac{1}{2}v^2 \tag{9.6.208}$$

But we have proved in the section of Music Mathematics that the speed of sound was given by:

$$v_{\text{sound}}=\sqrt{\frac{\gamma P}{\rho}}=\sqrt{\frac{\gamma RT}{M_m}}=\sqrt{\gamma rT} \tag{9.6.209}$$

where r is the ideal gas massic constant ...

Then we can write:

$$\frac{1}{\gamma-1}v_{\text{sound,eg}}^2=\frac{1}{\gamma-1}v_{\text{sound}}^2+\frac{1}{2}v^2\Leftrightarrow\frac{2}{\gamma-1}\frac{v_{\text{sound,eg}}^2}{v_{\text{sound}}}=\frac{2}{\gamma-1}+\left(\frac{v}{v_{\text{sound}}}\right)^2 \tag{9.6.210}$$

We then introduce the "Mach number":

$$\boxed{M=\frac{v}{v_{\text{sound}}}} \tag{9.6.211}$$

Therefore:

$$\frac{2}{\gamma-1}\frac{v_{\text{sound,eg}}^2}{v_{\text{sound}}^2}=\frac{2}{\gamma-1}+M^2 \tag{9.6.212}$$

But we also have:

$$\frac{v_{\text{sound,eg}}^2}{v_{\text{sound}}^2}=\frac{\gamma r T_{\text{eg}}}{\gamma r T}=\frac{T_{\text{eg}}}{T} \tag{9.6.213}$$

Hence after a small rearrangement:

$$\frac{v_{\text{sound,eg}}^2}{v_{\text{sound}}^2}=\frac{T_{\text{eg}}}{T}=1+\frac{\gamma-1}{2}M^2 \tag{9.6.214}$$

But using the relations proved above and obtained from the Laplace's law we get:

$$\frac{T_{\text{eg}}}{T}=\left(\frac{P_{\text{eg}}}{P}\right)^{\dfrac{\gamma-1}{\gamma}}=\left(\frac{V}{V_{\text{eq}}}\right)^{\gamma-1}=\left(\frac{\rho_{\text{eg}}}{\rho}\right)^{\gamma-1}=1+\frac{\gamma-1}{2}M^2 \tag{9.6.215}$$

✍**Example:**

Compressed air contained in a large tank escapes outward through a hole at a Mach number equal to $M=0.77$. Relaxation occurs in the atmosphere where there is an atmospheric pressure of 1.014 [bar]. The massic ratio of air at the NTP is given as being worth $\gamma=1.4$. We then have the pressure inside the tank which is given by:

$$\left(\frac{P_{\text{eg}}}{P}\right)^{\frac{\gamma-1}{\gamma}}=1+\frac{\gamma-1}{2}M^2\Rightarrow P_{\text{eg}}=P\left(1+\frac{\gamma+1}{2}M^2\right)^{\frac{\gamma}{\gamma-1}}\cong 1.5\,[\text{bar}] \tag{9.6.216}$$

We can also have fun by calculating the internal necessary pressure of the tank for the flow to become supersonic (and then do not forget that ... action = reaction... lol).

9.6.8.5 Thermoelastics coefficients

If we differentiate $V(P,T)$ we have (see Differential and Integral Calculus):

$$\mathrm{d}V=\frac{\partial V}{\partial T}\mathrm{d}T+\frac{\partial V}{\partial P}\mathrm{d}P \tag{9.6.217}$$

or written differently:

$$\mathrm{d}V=\left(\frac{\partial V}{\partial T}\right)_P\mathrm{d}T+\left(\frac{\partial V}{\partial P}\right)_T\mathrm{d}P \tag{9.6.218}$$

We have introduced naturally in the section Mathematical Music a coefficient named "coefficient of isothermal compressibility" that was for recall (the index T indicates that the temperature is kept constant):

$$\boxed{\chi_T=-\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T} \qquad (9.6.219)$$

that we can reintroduce here:

$$\mathrm{d}V=\left(\frac{\partial V}{\partial T}\right)_P\mathrm{d}T-\chi_T V\mathrm{d}P \qquad (9.6.220)$$

Also it would be interesting to have a different coefficient for the first term that it would suffice to define by analogy (the index V is there to indicate that this is a volumic coefficient and the P to indicate that we are at constant pressure):

$$\boxed{\alpha_{V,P}=\frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P} \qquad (9.6.221)$$

named "isobaric volume expansion coefficient".

Thus we have:

$$\mathrm{d}V=\alpha_{V,P}V\mathrm{d}T-\chi_T V\mathrm{d}P \qquad (9.6.222)$$

Therefore we have the mechanical work (the total differential is inaccurate because we have more than one state variable) by multiplying the pressure to have the correct units:

$$\delta W=\alpha_{V,P}PV\mathrm{d}T-\chi_T PV\mathrm{d}P \qquad (9.6.223)$$

For an isothermal transformation the first term is zero, and for an isobaric transformation, it is the second which is zero.

The fact to know the thermoelastic coefficients (measured experimentally) must bring us to fall back on the ideal gas law by integration of $V(P,T)$, which is minimum we should expect, since V is a state function. In the case of the ideal gas, for example, we can write intuitively by the dimensions of the constants (we will introduce further below during our study of the equations of state the reverse mathematical path for pedagogical reasons):

$$\alpha=\frac{1}{T} \qquad \chi=\frac{1}{P} \qquad (9.6.224)$$

Therefore we have:

$$\mathrm{d}V=\frac{V}{T}\mathrm{d}T-\frac{V}{P}\mathrm{d}P \qquad (9.6.225)$$

and therefore by multiplying by the pressure:

$$P\mathrm{d}V=\frac{PV}{T}\mathrm{d}T-V\mathrm{d}P\Rightarrow P\mathrm{d}V+V\mathrm{d}P=PV\frac{\mathrm{d}T}{T} \qquad (9.6.226)$$

Which leads to:

$$\mathrm{d}(PV)=PV\frac{\mathrm{d}T}{T} \qquad (9.6.227)$$

Therefore:

$$\frac{\mathrm{d}(PV)}{PV}=\frac{\mathrm{d}T}{T} \tag{9.6.228}$$

Giving immediately after integration:

$$\ln(PV)=\ln(T)+c^{te}\Rightarrow\ln\left(\frac{PV}{T}\right)=c^{te} \tag{9.6.229}$$

Remark

Notice that in the above relation we have something typical in Thermodynamics and Astrophysics: a logarithm of a non-dimensionless argument...!! The use for example of $\ln(T)$ etc. is always a shorthand for $\ln\left(T/T_0\right)$ which is okay to use if for some reason we don't care about T_0, i.e. because it cancels out or we are interested in the asymptotic behaviour only. So it's a lazy shorthand - the kind of thing much beloved by physicists...

Therefore:

$$PV=c^{te} \tag{9.6.230}$$

That said, we have differentiated V to get two coefficients such as:

$$\mathrm{d}V=\alpha V\mathrm{d}T-\chi V\mathrm{d}P \tag{9.6.231}$$

We could do the same for the pressure and temperature, and then we have a total of three relations:

$$\begin{aligned}\mathrm{d}V&=\left(\frac{\partial V}{\partial P}\right)_T\mathrm{d}P+\left(\frac{\partial V}{\partial T}\right)_P\mathrm{d}T\\ \mathrm{d}P&=\left(\frac{\partial P}{\partial T}\right)_V\mathrm{d}T+\left(\frac{\partial P}{\partial V}\right)_T\mathrm{d}V\\ \mathrm{d}T&=\left(\frac{\partial T}{\partial P}\right)_V\mathrm{d}P+\left(\frac{\partial T}{\partial V}\right)_P\mathrm{d}V\end{aligned} \tag{9.6.232}$$

but among the 6 factors that we see in these three relations, 4 are already defined (some are the opposite of the coefficients defined above). By cons a definition is missing for a single coefficient for the both missing factors. We choose the one that in practice is most often used by analogy to the other factors:

$$\boxed{\beta=\frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_V} \tag{9.6.233}$$

named "coefficient of increase of isochoric pressure".

We have therefore three very used coefficients in practice:

$$\chi_T=-\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_V\qquad\alpha_{V,P}=\frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P\qquad\beta=\frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_V \tag{9.6.234}$$

respectively in the order:

1. Coefficient of isothermal compressibility χ_T
2. Isobaric expansion coefficient $\alpha_{V,P}$
3. Isochoric pressure increasing coefficient β

We will see these coefficients again in our study of convective motions in the section of Weather & Marine Engineering.

9.6.9 Heat

Before continuing, we have at all costs to eliminate one of the greatest difficulties in the understanding of thermodynamics (apart from that of differentiation between correct and incorrect total differential that has already been set in the section of Differential and Integral Calculus):

- The difference between heat and temperature
- The difference between the energy-work and energy-heat

As we saw in the section of Continuum Mechanics, the temperature characterize a state of thermodynamic equilibrium and translates the existence of a thermal motion (virial theorem page 3897) and can vary when the outside provides a work $W>0$. However, experience shows us that it is by "heating" a system that we increase the more easily its temperature. But then what is the "heat"?

Let us consider a thermodynamic system in equilibrium, and let us write its total internal energy E as the sum of the products of the energy E of a microstate i by the population size P of the same microstate i:

$$E=\sum_i E_i P_i \tag{9.6.235}$$

Its variation during an infinitesimal transformation (which we assume with a constant number of particles) is (total differential):

$$\mathrm{d}E=\left(\frac{\partial E_i}{\partial P_i}\right)_{E_i}\mathrm{d}P_i+\left(\frac{\partial P_i}{\partial E_i}\right)\mathrm{d}E_i=\sum_i E_i\mathrm{d}P_i+\sum_i P_i\mathrm{d}E_i \tag{9.6.236}$$

where $\mathrm{d}E_i$ is the variation of the energy E_i of the microstate i caused by the transformation and $\mathrm{d}P_i$ the variation of the population P_i of this same microstate i.

We have seen earlier above that under certain conditions, if the system during the infinitesimal transformation undergoes a variation of work δW and of heat δQ, its internal energy varies of:

$$\mathrm{d}E=\mathrm{d}U=\delta W+\delta Q \tag{9.6.237}$$

We can now compare this last relation (expressing the first law of thermodynamics) with the one before (resulting from Statistical Mechanics) and identify the terms as follows:

$$\boxed{\mathrm{d}U=\sum_i E_i\mathrm{d}P_i+\sum_i P_i\mathrm{d}E_i=\delta W+\delta Q} \tag{9.6.238}$$

Let us examine the case of processing in which the system receives only heat:

$$\delta W = 0 \quad (9.6.239)$$

In this situation no external parameters to the system generally varies in the transformation so that $\mathrm{d}E_i = 0$. We conclude:

$$\delta Q = \sum_i E_i \mathrm{d}P_i \quad (9.6.240)$$

Thus, when a system receives only heat, its energy vary by the change of the populations of its microstates: If the amount of heat received is positive, the probability of the high energy microstates increases, at the expense of the microstates of lower energy. Finally, if we take into account that the system must be in equilibrium (the most probable state as we have proved it in the section of Statistical Mechanics) in the initial and final states of transformation, we find, as we should expect, that the system temperature varies: it has increased if the amount of heat received is positive (this can be proved by choosing a canonical distribution to describe the system of macroscopic equilibrium states as done in the section of Statistical Mechanics).

This explains the frequent confusion between these two very different concepts that are temperature and heat. This confusion is compounded by the gap between everyday language and scientific terminology. In everyday language, when we talk about "heat" of a body, we say actually that its temperature is high. The confusion is unfortunate because the concept of heat is present in physics but its meaning is different.

Thus, heat a system, is provide heat to it, is increasing its internal energy (the number of high-energy micro-states) by means that are not purely mechanical. The heat is thus a particular form of energy!

9.6.9.1 Entropy

An isolated macroscopic system tends towards equilibrium. It reached it in a finite time (which can be extremely long). The steady state is unique: the exceptions to this claim are too special to merit a digression at least for now.

The very existence of a state of equilibrium is fundamental to thermodynamics. However, the equilibrium walk process is not due to a dogma: there must be no dogma in physics as we know (and in science in general)! Like any other law, it is subject verified experimentally and must be analysed. One question in particular arises: what is the microscopic counterpart of the equilibrium walk process, that is a macroscopic process also.

We proved in the section Statistical Mechanics that by definition: the equilibrium state is the state which is have the largest number of configurations (microstates) and is the most probable state.

What had brought us to the following relation (see page 3525):

$$S = \lambda \ln(\Omega) \tag{9.6.241}$$

where S represents the statistical expected mean of information on microstates and that we named for recall "entropy". Clearly S has the units of λ that as we showed it is a constant.

The question that arises in thermodynamics is: what is the constant that permits characterize for a gas, liquid or solid the expected number of microstates.

Then it comes when looking at all the relation in thermodynamics one constant that always appears when it comes to characterize a thermodynamic state. This is the Boltzmann constant:

$$\lambda = k = 1.3806 \cdot 10^{-23}\,[\mathrm{J} \cdot \mathrm{K}^{-1}] \tag{9.6.242}$$

So S has units corresponding to the ratio J / K that thus permits to measure the degree of disorder in a system at the microscopic level. Intuitively: the higher the entropy of the system, the less its elements are ordered and capable of producing mechanical effects, and the greater the part of energy unused or used inconsistently.

The entropy is an extensive quantity. Indeed, we have proved that the choice of the logarithm in the Boltzmann law came from the fact that the entropy of a macro state was the expected mean of all microstates:

$$\begin{aligned} S &= -\lambda \sum_{i=1}^{n} p_i \log(p_i) = -\lambda \left(\frac{1}{\Omega} \log\left(\frac{1}{\Omega}\right) + \frac{1}{\Omega} \log\left(\frac{1}{\Omega}\right) + \ldots + \frac{1}{\Omega} \log\left(\frac{1}{\Omega}\right) \right) \\ &= -\lambda \left(-\frac{1}{\Omega} \log(\Omega) - \frac{1}{\Omega} \log(\Omega) - \ldots - \frac{1}{\Omega} \log(\Omega) \right) = \lambda \log(\Omega) \left(\frac{1}{\Omega} + \frac{1}{\Omega} + \ldots + \frac{1}{\Omega} \right) \end{aligned} \tag{9.6.243}$$

what had brought us to:

$$S = \lambda \ln(\Omega) \tag{9.6.244}$$

and shows well that entropy is an extensive quantity because summable on micro-states (complexions).

What remains difficult now is whether to know if the energy in the units of entropy comes from the work W or from heat Q or from both? In fact the answer is quite simple because in our development of the Boltzmann law, at any time the system (ideal) studied has provided (mechanical) work. So the only energy involved is that of heat.

Therefore:

$$S=\frac{Q}{T} \tag{9.6.245}$$

However, entropy can not be given rigorously by:

$$S=\frac{\Delta Q}{\Delta T} \tag{9.6.246}$$

because that is the definition of specific heat! Furthermore, if the reader remembers our developments in the section of Statistical Mechanics, the study was done in an isolated system with two cavities. So if the transition from one cavity to the other is very slow (so that there is not an expansion of the gas) the temperature will remain constant (isothermal expansion). Which implies the definition (so we fall back on the discrete form of the second law of thermodynamics already introduced at the beginning of this section):

$$\Delta S=\frac{\Delta Q}{T} \tag{9.6.247}$$

To move to the differential form, it should be remembered that heat Q is an inexact differential. So for a reversible transformation:

$$\mathrm{d}S=\frac{\delta Q}{T} \tag{9.6.248}$$

Therefore the entropy is an exact total differential (heat depends on how the transformation takes place, but S depends only on the final and initial state of the heat Q) and as:

$$S=\lambda\ln(\Omega)\geq 0 \tag{9.6.249}$$

Finally we have in an adiabatic (constant energy), closed and finite system within a static space-time:

$$\boxed{S=\frac{\delta Q}{T}\geq 0} \tag{9.6.250}$$

That's the second law of thermodynamics! If the system is finite and in an adiabatic transformation (without heat and work exchange - energy - with the outside), then the numerator is zero and the entropy is also zero verbatim (this is why an adiabatic process is necessarily isentropic!). Otherwise, the system takes the entropy to the Universe in a natural evolution.

This means that the entropy (expected mean of the intrinsic information) in a system in contact with the outside can only increase or remain constant.

What is important is that any processes (non-adiabatic) converting energy from one form to another in an isolated system necessarily loses some form of heat.

Regarding the Universe ... the question is whether this is an isolated thermodynamic system or not and finite or not and static or not...!? There are therefore a few difficulties with our Universe:

- We can observe and do measurements only for the observable Universe! The Universe in it's entirety isn't observable and therefore we can't measure the value of its entropy (there are only actually speculative theoretical models that try to speculate the entropy for the observable Universe).

- Modern measurements give evidence that our observable Universe is flat and therefore the entire Universe may be infinite (hence it is not closed). And as the second law of thermodynamics holds only for finite closed systems therefore we don't know if the latter can be applied to our Universe or not.

- As we have already prove it with the Noeother theorems (see page 3132), if space-time isn't static then energy isn't conversed and therefore the second law of thermodynamics doesn't applied. And actually all empirical measurement show that the space-time structure of our observable Universe is dynamic. Therefore for the observable Universe the second principle of thermodynamics doesn't hold.

Hence although it is attempting to apply thermodynamics to the whole Universe, and some of the founding fathers of Thermodynamics did it and also some scientists still do it because of the publish or perish paradigm..., a closer inspection of the problem suggest some caution as show with our enumeration above!

> Caution!!! There is no principle of physics yet (in the beginning in the 121st century according to holocene calendar) that says physicals laws or constants have to be the same everywhere and always. Indeed, the reader must remember that the "laws" of physics are **descriptive**, not **imperative** and therefore they are some observed regularity in what we can observe experimentally with sufficiently wide occurrence or relevance! Asking whether the laws can change is no more and no less than asking whether regularities which have been observed up till now might not be quite as universal as was thought. The answer to that is: YES! This could drive the reader a bit mad. Indeed, how can we possibly do Science if the rules keep changing? But if you are a professional active scientist, you have to face up to that possibility - and you have a responsibility to check out if there is evidence beyond reasonable doubt about it! We will repeat this warning multiple times in this textbook as its seems that this is something necessary!

We then have the very useful relation in fluid mechanics (and cosmology):

$$\boxed{\mathrm{d}U=\delta Q+\delta W=T\mathrm{d}S-P\mathrm{d}V} \tag{9.6.251}$$

which is named "thermodynamic identity" relatively to the internal energy U or "characteristic function of a fluid at equilibrium" or more often "fundamental Gibbs' equation" (we will notice that it is a sum of products of intensive and extensive quantities). If the amount of material is not constant (material inserted or extracted from the system), the latter relation is then written for a variation of moles $\mathrm{d}n$:

$$\boxed{\mathrm{d}U=T\mathrm{d}S-P\mathrm{d}V+\mu\mathrm{d}n} \tag{9.6.252}$$

where μ is a coefficient of proportionality named "chemical potential" and can therefore be measured by the fact that the previous relation leads to the definition:

$$\boxed{\mu=\left(\frac{\partial U}{\partial n}\right)_{S,V}} \tag{9.6.253}$$

which means that the chemical potential μ is, as we already know, the internal energy variation of the gas when we inject it in or withdraw from it $\mathrm{d}n$ moles of gas, while keeping constant the volume of the tank and prohibiting heat exchange with the environment.

We can often found in the prior previous relations follows after a simple rearrangement in many text books (and assuming constant the quantity of material):

$$\mathrm{d}S=\frac{\mathrm{d}U}{T}+\frac{P}{T}\mathrm{d}V \tag{9.6.254}$$

The latter relation is often assimilated to the first law of thermodynamics for closed systems for whose the overall variation of potential and kinetic energy is constant.

Let us notice that by using the relation between the internal variation of energy of an ideal monoatomic gas in function of its temperature at constant volume as proved earlier above (first Joule's law):

$$\mathrm{d}U=C_V\mathrm{d}T \tag{9.6.255}$$

and the ideal gas equation (see section Continuum Mechanics page 3903):

$$PV=nRT \tag{9.6.256}$$

We then have using the molar heat capacity at constant volume (remember that we can inject into this relation only for an ideal gas because it is then independent of the volume!):

$$\mathrm{d}S=nc_V^M\frac{\mathrm{d}T}{T}+nR\frac{\mathrm{d}V}{V} \tag{9.6.257}$$

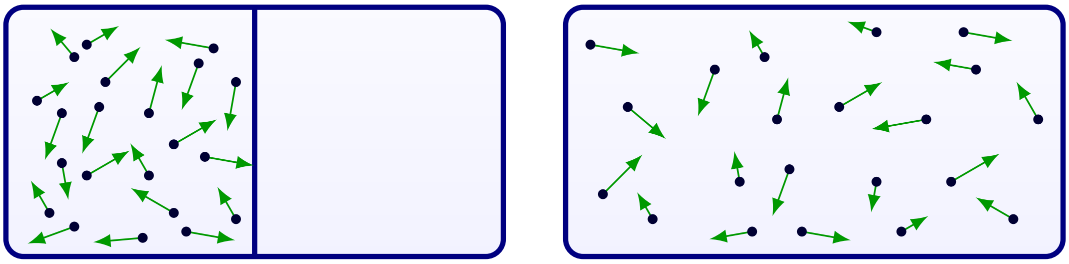
So integrating between two states, we get:

$$\begin{aligned}\Delta S&=\int\limits_1^2\mathrm{d}S=\int\limits_1^2 nc_V^M\frac{\mathrm{d}T}{T}+nR\frac{\mathrm{d}V}{V}=\int\limits_1^2 nc_V^M\frac{\mathrm{d}T}{T}+\int\limits_1^2 nR\frac{\mathrm{d}V}{V}\\&=nc_V^M\int\limits_1^2\frac{\mathrm{d}T}{T}+nR\int\limits_1^2\frac{\mathrm{d}V}{V}=nc_V^M\ln(T)|_1^2+nR\ln(V)|_1^2=nc_V^m\ln\left(\frac{T_2}{T_1}\right)+nR\ln\left(\frac{V_2}{V_1}\right)\end{aligned} \tag{9.6.258}$$

Thus the entropy change of an ideal gas at constant pressure:

$$\Delta S=nc_V\ln\left(\frac{T_2}{T_1}\right)+nR\ln\left(\frac{V_2}{V_1}\right) \tag{9.6.259}$$

And for the famous case at constant temperature known as "Joule expansion" as illustrated below:



We have therefore:

$$\Delta S = nR\ln\left(\frac{V_2}{V_1}\right) \geq 0 \tag{9.6.260}$$

And as we have also proved above that:

$$c_V^M = \frac{3}{2}R \tag{9.6.261}$$

It comes therefore by using the algebraic properties of the logarithm:

$$\begin{aligned}\Delta S &= \frac{3nR}{2}\ln\left(\frac{T_2}{T_1}\right) + nR\ln\left(\frac{V_2}{V_1}\right) = nr\left[\frac{3}{2}\ln\left(\frac{T_2}{T_1}\right) + \ln\left(\frac{V_2}{V_1}\right)\right] \\ &= nR\left[\ln\left(\left(\frac{T_2}{T_1}\right)^{3/2}\right) + \ln\left(\frac{V_2}{V_1}\right)\right] = nR\ln\left(\left(\frac{T_2}{T_1}\right)^{3/2}\frac{V_2}{V_1}\right)\end{aligned} \tag{9.6.262}$$

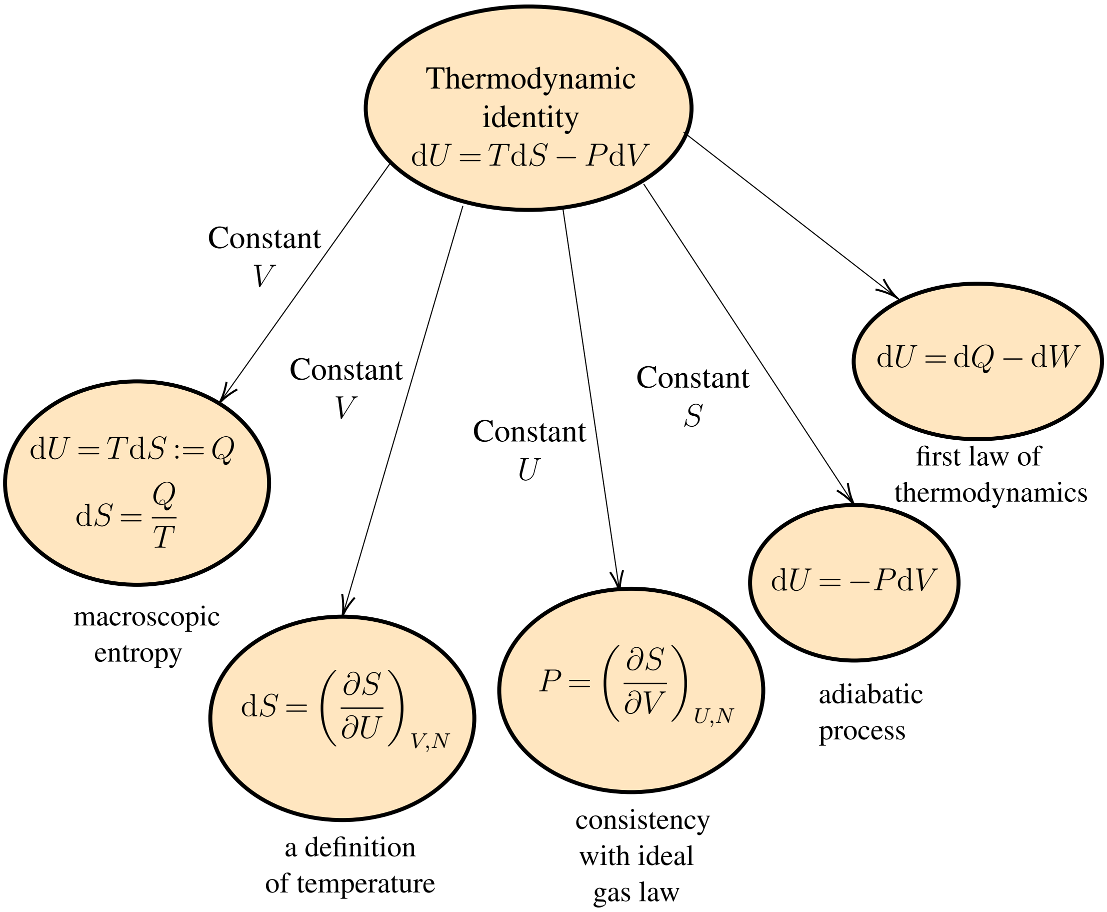
And as in practice it is easier to measure the pressure than the volume, we use the ideal gas law where at constant temperature we have (see section Continuum Mechanics page 3890):

$$P_1V_1 = P_2V_2 \tag{9.6.263}$$

to get the very important next result in practice considered the entropy change of an ideal gas at constant volume:

$$\boxed{\Delta S = nR\ln\left(\left(\frac{T_2}{T_1}\right)^{3/2}\frac{P_1}{P_2}\right)} \tag{9.6.264}$$

The reader must not forget that if the calculation with numerical applications give negative values for the change in entropy then the interpretation is quite simple: that means that the direction of the arbitrary considered transformation is not the real (natural) direction in which would conduct the system left to itself in the Universe (i.e. it is then an artificial transformation).



Thermodynamic identity
$\mathrm{d}U = T\mathrm{d}S - P\mathrm{d}V$
Constant V
Constant V
Constant U
Constant S
$\mathrm{d}U = \mathrm{d}Q - \mathrm{d}W$
first law of thermodynamics
$\mathrm{d}U = T\mathrm{d}S := Q$
$\mathrm{d}S = \dfrac{Q}{T}$
macroscopic entropy
$\mathrm{d}U = -P\mathrm{d}V$
adiabatic process
$\mathrm{d}S = \left(\dfrac{\partial S}{\partial U}\right)_{V,N}$
a definition of temperature
$P = \left(\dfrac{\partial S}{\partial V}\right)_{U,N}$
consistency with ideal gas law

Now let us derive the entropy expression based on the canonical partition function as promised in the section of Statistical Mechanics!

By definition (see section Statistical Mechanics page **??**) the canonical partition function is $Z_e = \sum_i e^{-\beta E_i}$, where $\beta = \frac{1}{k_B T}$ and E_i are the energy levels.

The probability P_i of finding the system in a specific microstate i is given by the Boltzmann distribution (still see **??**):

$$p_i = \frac{e^{-\beta E_i}}{Z} \tag{9.6.265}$$

Statistical mechanics defines entropy via the Shannon entropy formula (see section Statistical Mechanics page 3530):

$$S = -k_B \sum_i p_i \ln(p_i) \tag{9.6.266}$$

Therefore:

$$S = -k_B \sum_i p_i \left(-\beta E_i - \ln(Z)\right) = k_B \beta \sum_i p_i E_i + k_B \ln(Z) \sum_i p_i \tag{9.6.267}$$

Note that the sum of all probabilities equals one ($\sum_i p_i = 1$) and the average energy is $U = \sum_i p_i E_i$, therefore:

$$S = k_B \beta U + k_B \ln(Z) \tag{9.6.268}$$

Replacing β with $1/k_BT$, leads to:

$$S = \frac{U}{T} + k_B \ln(Z) \tag{9.6.269}$$

Alternatively, since (see section page **??**):

$$U = -\frac{\partial \ln(Z)}{\partial \beta} \tag{9.6.270}$$

this can be written directly in terms of temperature derivatives as:

$$\boxed{S = k_B \ln(Z) + k_BT \left(\frac{\partial \ln(Z)}{\partial T}\right)_V} \tag{9.6.271}$$

Now let us derive the entropy expression based on the canonical partition function as promised in the section of Statistical Mechanics!

By definition (see section Statistical Mechanics page **??**) the canonical partition function is $Z_c = \sum_i e^{-\beta E_i}$, where $\beta = \frac{1}{kT}$ and E_i are the energy levels.

The probability P_i of finding the system in a specific microstate i is given by the Boltzmann distribution (still see **??**):

$$p_i = \frac{e^{-\beta E_i}}{Z_c} \tag{9.6.272}$$

Statistical mechanics defines entropy via the Shannon entropy formula (see section Statistical Mechanics page 3530):

$$S = -k \sum_i p_i \ln(p_i) \tag{9.6.273}$$

Therefore:

$$S = -k \sum_i p_i \left(-\beta E_i - \ln(Z_c)\right) = k\beta \sum_i p_i E_i + k \ln(Z_c) \sum_i p_i \tag{9.6.274}$$

Note that the sum of all probabilities equals one ($\sum_i p_i = 1$) and the average energy is $U = \sum_i p_i E_i$, therefore:

$$S = k\beta U + k \ln(Z_c) \tag{9.6.275}$$

Replacing β with $1/kT$, leads to:

$$S = \frac{U}{T} + k \ln(Z_c) \tag{9.6.276}$$

Alternatively, since (see section page 3911):

$$U = -\frac{\partial \ln(Z_c)}{\partial \beta} \tag{9.6.277}$$

this can be written directly in terms of temperature derivatives as:

$$\boxed{S = k \ln(Z_c) + kT \left(\frac{\partial \ln(Z_c)}{\partial T}\right)_V} \tag{9.6.278}$$

9.6.9.1.1 Life, evolution, and the second law of thermodynamics

Some people misunderstand the second law of thermodynamics, stated in terms of entropy, to say that the process of the evolution of life violates this law. Over time, complex organisms evolved from much simpler ancestors, representing a large decrease in entropy of the Earth's biosphere. It is a fact that the huge majority of living organisms have evolved (for more information see the excellent [453]) to be highly structured, and much lower in entropy than the substances from which they grow. But it is always possible for the entropy of one part of the universe to decrease, provided the total change in entropy of the universe increases. In equation form, we can write this as $\Delta S_{\text{tot}} = \Delta S_{\text{syst}} + \Delta S_{\text{envir}} > 0$.

Thus ΔS_{syst} can be negative as long as ΔS_{envir} is positive and greater in magnitude.

How is it possible for a system to decrease its entropy? Energy transfer is necessary! If we pick up marbles that are scattered about the room and put them into a cup, our work has decreased the entropy of that system. If we gather iron ore from the ground and convert it into steel and build a bridge, our work has decreased the entropy of that system. Energy coming from the Sun (actually a G2V-type star, aka yellow dwarf) can decrease the entropy of local systems on Earth that is, ΔS_{syst} is negative. But the overall entropy of the rest of the universe increases by a greater amount-that is, ΔS_{envir} is positive and greater in magnitude. Thus, $\Delta S_{\text{tot}} = \Delta S_{\text{syst}} + \Delta S_{\text{envir}} > 0$, and the second law of thermodynamics is not violated.

Every time a plant stores some solar energy in the form of chemical potential energy, or an updraft of warm air lifts a soaring bird, the Earth can be viewed as a heat engine operating between a hot reservoir supplied by the Sun and a cold reservoir supplied by dark outer space-a heat engine of high complexity, causing local decreases in entropy as it uses part of the heat transfer from the Sun into deep space. There is a large total increase in entropy resulting from this massive heat transfer. A small part of this heat transfer is stored in structured systems on Earth, producing much smaller local decreases in entropy.

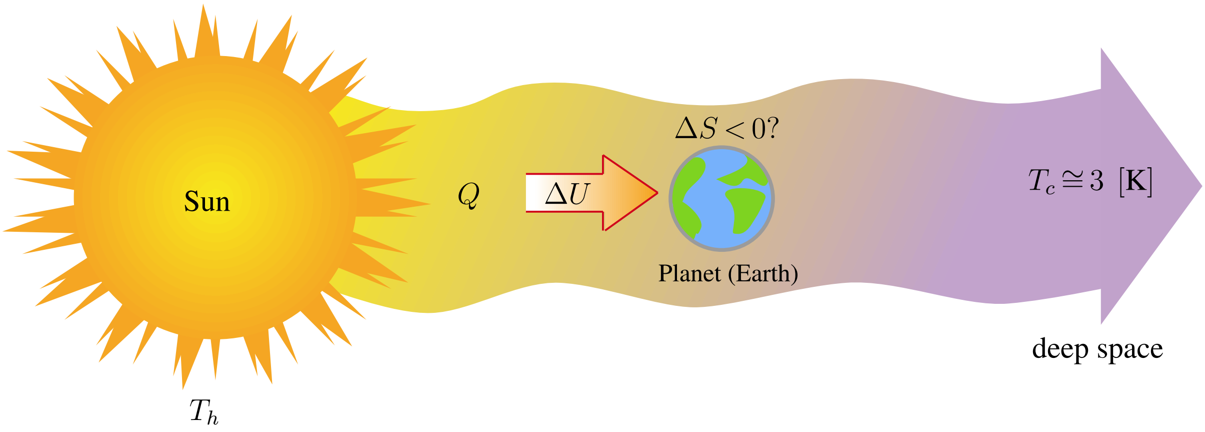


Figure 9.167: **Earth's entropy may decrease in the process of intercepting a small part of the heat transfer from the Sun into deep space (not to scale)**

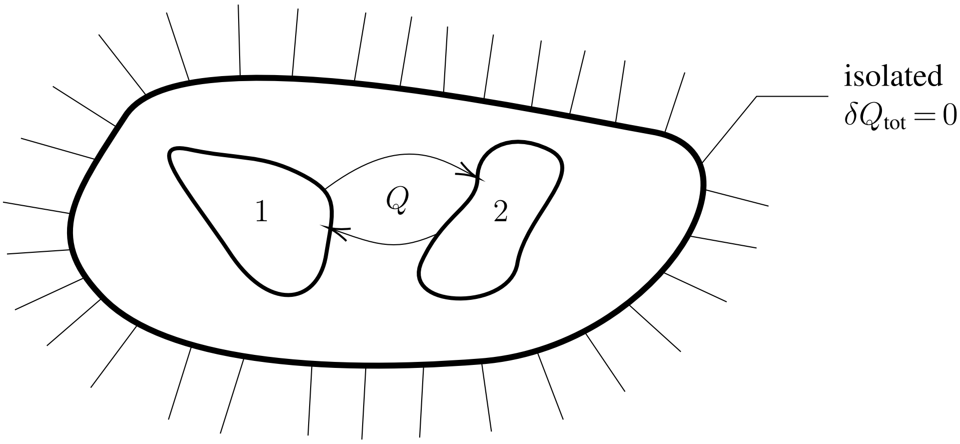
Sun is a (nice) source of low entropy for Earth: A concentrate of energy that permits life to be structure itself! For each photon of the Sun of a given energy received the Earth will re-emit the equivalent concentrate energy (low entropy) in the form of an average of twenty photons of dissipated energy (higher entropy). The Sun get itself its low entropy it gives to Earth from gravity. As in a closed system... gravity can decrease entropy by concentrating matter in a small volume of space!

9.6.9.1.2 Heat Flow

Now that we have introduced the basics of thermodynamics let do on an example of very important application of the first and second laws of thermodynamics.

Let us consider two closed systems 1 and 2 being in thermal contact and forming a total system that is assumed thermally isolated from the environment:



In both systems, there are no mechanical parts, such as pistons or other, that can work. Therefore:

$$\delta W_1=\delta W_2=\delta W_{\text{tot}}=0 \tag{9.6.279}$$

The conditions and assumptions being known, we use ingredients of thermodynamics to make our recipes. It then comes by applying the first principle as proved above in a first time for the whole:

$$\begin{aligned}\mathrm{d}U_{\text{tot}}&=\mathrm{d}U_1+\mathrm{d}U_2\\ \mathrm{d}U_{\text{tot}}&=\underbrace{\delta Q_{\text{tot}}}_{=0}+\underbrace{\delta W_{\text{tot}}}_{=0}=0\end{aligned} \tag{9.6.280}$$

We deduce that:

$$\mathrm{d}U_1+\mathrm{d}U_2=0 \tag{9.6.281}$$

We also have for each sub-system:

$$\begin{aligned}\mathrm{d}W_1&=0=\mathrm{d}U_1-\delta Q_1\\ \mathrm{d}W_2&=0=\mathrm{d}U_2-\delta Q_2\end{aligned} \tag{9.6.282}$$

Hence we deduce from the latter system of equations by summing:

$$\mathrm{d}U_1+\mathrm{d}U_2=\delta Q_1+\delta Q_2 \tag{9.6.283}$$

and as we have proved just before:

$$\mathrm{d}U_1+\mathrm{d}U_2=0 \tag{9.6.284}$$

It comes:

$$\mathrm{d}U_1+\mathrm{d}U_2=0=\delta Q_1+\delta Q_2 \tag{9.6.285}$$

and therefore (obvious!):

$$\delta Q_1=-\delta Q_2 \tag{9.6.286}$$

Let us now apply the second principle (principle of evolution). We have:

$$\mathrm{d}S_{\text{tot}}=\mathrm{d}S_1+\mathrm{d}S_2=\frac{\delta Q_1}{T_1}+\frac{\delta Q_2}{T_2}=\frac{\delta Q_{\text{tot}}}{T_1} \tag{9.6.287}$$

But with the prior previous relation, we have:

$$\mathrm{d}S_{\text{tot}}=\frac{\delta Q_1}{T_1}+\frac{-Q_1}{T_2}=\delta Q_1\left(\frac{1}{T_1}-\frac{1}{T_2}\right) \tag{9.6.288}$$

We now have two possible scenarios. For the first, we have:

$$T_2>T_1\rightarrow\left(\frac{1}{T_1}-\frac{1}{T_2}\right)>0 \tag{9.6.289}$$

and when:

$$T_2<T_1\Rightarrow\delta Q_1>0 \tag{9.6.290}$$

Therefore:

$$\mathrm{d}S_{\text{tot}}>0 \tag{9.6.291}$$

For the second scenario, we have:

$$T_1>T_2\rightarrow\left(\frac{1}{T_1}-\frac{1}{T_2}\right)y0 \tag{9.6.292}$$

and when:

$$T_1>T_2\Rightarrow\delta Q_1<0 \tag{9.6.293}$$

Therefore:

$$\mathrm{d}S_{\text{tot}}>0 \tag{9.6.294}$$

We conclude that whatever happens, entropy increases for an isolated system in a static space-time without gravity. This result is therefore consistent with what we communicated during our presentation of the second principle. So this result proves the impossibility for an isolated dithermal thermal machine to provide a perpetual work because the entropy can only increase in all cases!

We also see, as we have already mentioned it, that entropy defines the arrow of time in the Universe (or vice versa).

9.6.9.2 Carnot Cycle

The Carnot cycle's main objective is to calculate the thermal efficiency of a thermodynamic cycle of a dithermal idealized machine ... (so the model is far from the practice!) Based on a heat source from which we take heat to turn it into work and then from which we use work to provide heat and so on in loop(think of a locomotive for example!). We speak then of "reverse cycle".

The idea is pretty simple ... but as always someone had to think to it first!

For information we have chosen here a mathematical approach of the Carnot cycle which allows to avoid any integral and that is closer to the reasoning made at the time of Carnot by colas Léonard Sadi Carnot himself. This approach can therefore make bristle the hair to some readers ...

From the perspective of the internal energy, on a thermodynamic cycle, there will be no variations (since at each cycle beginning we must found ourselves in the situation of the previous cycle). Therefore:

$$\Delta U=0 \qquad (9.6.295)$$

This is so far simply a recall of the principle of conservation of energy (first law of thermodynamics).

This means that on a cycle the heat balance Q_e borrowed by the machine to produce a (mechanical) work W_p and of the heat Q_i re-injected and that required a (mechanical) work W_i is zero on a cycle such that:

$$Q_e+Q_i+W_p+W_i=0 \qquad (9.6.296)$$

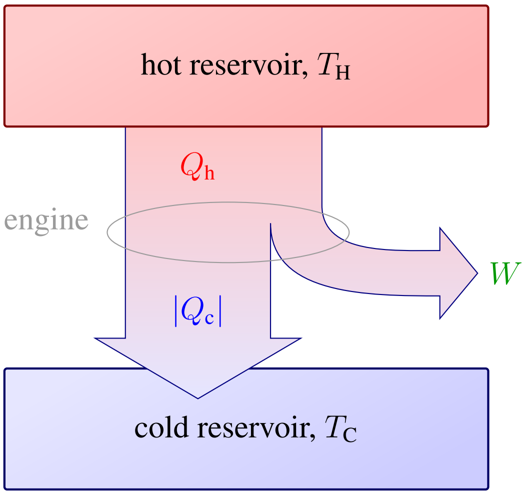
where what is obviously borrowed will, as it is customary, have a positive sign and what is injected a negative sign !!!!! It is customary to notice this last relation in the following condensed form:

$$Q_e+Q_i+W=0 \Leftrightarrow W=-(Q_e+Q_i) \qquad (9.6.297)$$

The "thermal efficiency" η is defined as the ratio of the work that machine can really provide (i.e. the difference between what it gives W_p and what we must give to it W_i so that it works) on heat that was injected (with the working equation). So:

$$\boxed{\eta=\frac{|W_p+W_i|}{Q_i}=\frac{|W|}{Q_i}=\frac{|-(Q_e+Q_i)|}{Q_i}=\frac{Q_e+Q_i}{Q_i}=1+\frac{Q_e}{Q_i}} \qquad (9.6.298)$$

which is always less than 1 (and greater than 0), since the amount of heat removed (positive sign by convention) is necessarily less than or equal to the amount of injected heat (negative sign by convention).



hot reservoir, T_{H}
Q_{h}
engine
W
$|Q_{\mathrm{c}}|$
cold reservoir, T_{C}

Figure 9.168: **A schematic representation ("heat bath scheme") of a heat engine**

However, we have proved that in the conditions of isothermal expansion or isothermal compression (so the cycle is assumed to be very slow in the Cournot model), we had:

$$\Delta Q = T\Delta S \tag{9.6.299}$$

But, in our case Q_e, Q_i are in reality an abusive notation in thermodynamics as it is heat variation (we should notice them objectively ΔQ_e,ΔQ_i). We then have for the reversible thermal efficiency for isothermal compression or expansion:

$$\eta = 1 + \frac{T_e \Delta S_e}{T_i \Delta S_i} \tag{9.6.300}$$

The transformation being quasi-static, the relation obtained is obviously the theoretical maximum efficiency for an engine operating between these temperatures. It is never reached in a real cycle! We then say that the "Carnot efficiency" is a maximum (the entropy injected being in a real case always greater than the entropy extracted by construction!).

This leads us to the "Kelvin-Planck statement" that says:

- First alternative: it (seems as far as we know) that it is impossible to design a thermal machine that describes a cycle and that would have for only effect to produce work and to exchange heat with a single thermal tank.
- Second alternative: it is impossible for a thermal machine making a cyclic process to convert entirely into work the heat it absorbs.

In the case of a steam engine, the maximum theoretical efficiency would be (remember that the temperature is in Kelvin, and always positive!):

$$\eta = 1 - \frac{T_e}{T_i} = 1 - \frac{273+25}{273+100} \cong 0.2 = 20\% \tag{9.6.301}$$

For example in the case of a central nuclear working with pressurized water, we find the famous performance often mentioned in the press:

$$\eta = 1 - \frac{T_e}{T_i} \cong 1 - \frac{273+35}{273+285} \cong 45\% \tag{9.6.302}$$

The real thermal efficiency of the conversion of nuclear fission heat to electricity is in the order of only 33% because the real thermal efficiency is always less than the theoretical maximum thermal efficiency! At the time of Carnot the theoretical efficiency of a steam engine was 32%. However in practice because of heat dissipation, friction, etc. the practical efficiency of a steam engine was around 3% only!

Remark

Notice that to reach a 100% efficiency the last relation would require absolute zero to one side or infinite temperature to the other side...

Here are some other values:

Type	Carnot efficiency
Electric generator	$70-99\%$
Dry battery	90%
Industrial electric motor	$60-90\%$
Hydrogen-oxygen fuel cell	60%
Diesel motor	$34-50\%$
Liquid fuel rocket	47%
Steam turbine	$34-46\%$
Fossil fuel power station	40%
GE90 (Boeing 777)	36.1%
Nuclear Fuel Power Plant	32%
Petrol engine	27%
Human body	25%
Solar Cell	$20-30\%$
Piston engine	$10-25\%$

Table 9.29: Some typical Carnot efficiencies

The relation:

$$\eta=1-\frac{T_e}{T_i} \tag{9.6.303}$$

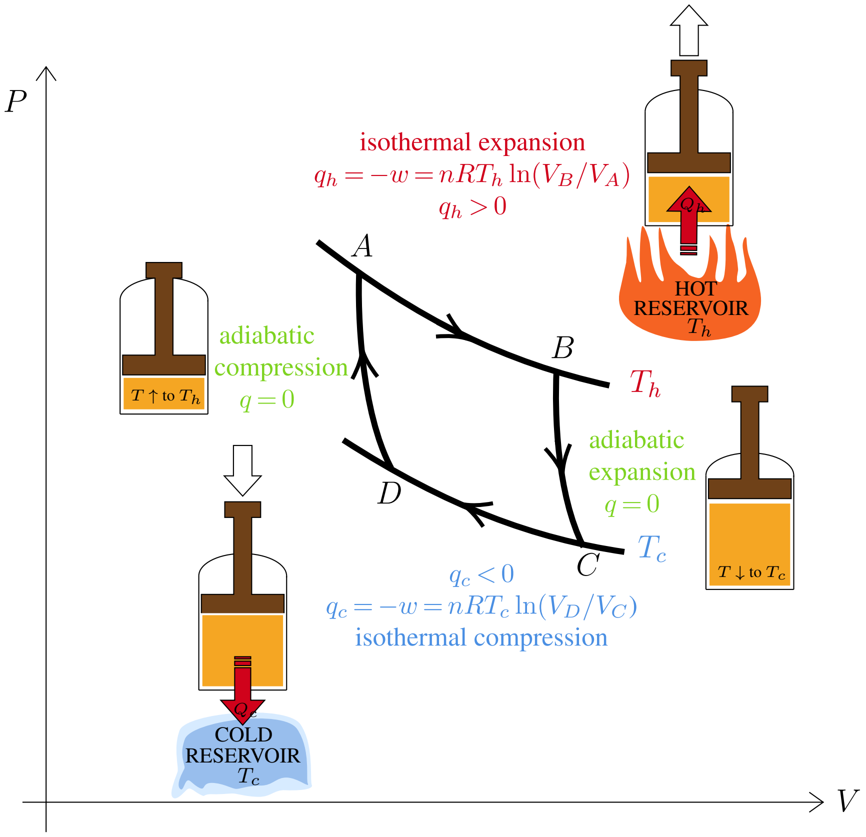
has a very useful interest in practice. Indeed, if an engineer said to have built a machine that is able to convert for example 1000 [kJ] in input in 410 [kJ] of pure work with an efficiency of 41%, then other engineers can check if this thermal efficiency is overestimated by measuring the temperature of the input source and that of the output.

Remark

We may notice the interest of the condenser. If we let escape to the atmosphere the steam coming out of turbines, firstly we would lose purified water instead of recycling it (for reuse in the cycle), on the other part we would have a heat source of higher temperature: 100 [°C] instead of 100 [°C] we would lose about 12% of the Carnot efficiency.

Finally, we implicitly also find one of the historical statements of the second law of thermodynamics considering where equation. In this case, it is not effective and the engine does not therefore provide any work.

Let us return briefly to the fact that in the ideal case of the cycle considered above which for recall is therefore an ideal thermodynamic cycle consisting of four reversible processes: isothermal expansion, adiabatic expansion (so isentropic because reversible), isothermal compression, and adiabatic compression... :



P
V
isothermal expansion
$q_h=-w=nRT_h\ln(V_B/V_A)$
$q_h>0$
A
B
C
D
T_h
T_c
HOT RESERVOIR T_h
Q_h
adiabatic compression
$q=0$
$T\uparrow$ to T_h
adiabatic expansion
$q=0$
$T\downarrow$ to T_c
$q_c<0$
$q_c=-w=nRT_c\ln(V_D/V_C)$
isothermal compression
Q_c
COLD RESERVOIR T_c

Figure 9.169: **Carnot cycle illustration**

we were led to write:

$$\Delta S_{\text{cyc.}}=\Delta S_e+\Delta S_i=0 \tag{9.6.304}$$

But the second law of thermodynamics says that the entropy change is always positive or zero, what we wrote for recall:

$$\mathrm{d}S=\frac{\delta Q}{T}\geq 0 \tag{9.6.305}$$

but in the above reversible case, for the cyclic variation of entropy of the reversible process to be zero that mean that one of the both term violates must violate this principle (at least in the case of a cycle) and therefore has a negative entropy (so that the sum is zero) such that we are led to write:

$$\mathrm{d}S=\frac{\delta Q}{T}\leq 0 \tag{9.6.306}$$

It is a violation of the reality that thermodynamicists name "Clausius inequality". It is then customary to summarize the thermodynamic cycles as follows:

- $\displaystyle\oint\frac{\delta Q}{T}=0$: no irreversibility in the system

- $\oint \dfrac{\delta Q}{T} > 0$: irreversibilities in the system (the reality of our Universe)
- $\oint \dfrac{\delta Q}{T} < 0$: impossible (at least as far as we know...)

As the second relation listed above is not possible we then have for any system exchanging heat with external reservoirs and undergoing a cyclic process:

$$\boxed{\Delta S = \oint \frac{\delta Q}{T} \leq 0} \tag{9.6.307}$$

that is also named "Clausius theorem".

This theorem can be proved but all the proofs I know so far are not aesthetic in my point of view. But it's quite obvious and this relation is just a special case of the second principle of thermodynamics.

Especially the case if during a cycle no information is lost (as we have proved in the section of Statistical Mechanics, entropy is related to information!) is quite obvious that:

$$\Delta S = \oint \frac{\delta Q}{T} \leq 0 \tag{9.6.308}$$

9.6.10 Maxwell relations

Maxwell's relations are a set of equations in thermodynamics which are derivable from the symmetry of second derivatives and from the definitions of the thermodynamic potentials. These relations can be useful when we are not able to directly measure a given thermodynamics property but that we can workaround this issue by expressing it in terms of other thermodynamic variables.

Let us return first to what we have already mentioned a little earlier above but by restricting ourselves to two variables. That is to say the exact total differential:

$$\mathrm{d}z = M\mathrm{d}x + N\mathrm{d}y = \frac{\partial z}{\partial x}\mathrm{d}x + \frac{\partial z}{\partial y}\mathrm{d}y = \left(\frac{\partial z}{\partial x}\right)_y \mathrm{d}x + \left(\frac{\partial z}{\partial y}\right)_x \mathrm{d}y \tag{9.6.309}$$

When we assume that we are authorized to write the differential of a state variable in thermodynamics as above, and especially for a simple compressible system that is completely specified by two independent, intensive properties, then we say that we are using the "state postulate".

Remark

Two properties are considered independent if one can be varied while the other is held constant. For example, temperature and specific volume are always independent. However, temperature and pressure are independent only for a single-phase system; for a multiphase system (such as a mixture of gas and liquid) this is not the case. (e.g., boiling point (temperature) depends on elevation (ambient pressure)).

So we have also:

$$\begin{aligned}\mathrm{d}x&=\left(\frac{\partial x}{\partial y}\right)_z\mathrm{d}y+\left(\frac{\partial x}{\partial z}\right)_y\mathrm{d}z\\ \mathrm{d}y&=\left(\frac{\partial y}{\partial x}\right)_z\mathrm{d}x+\left(\frac{\partial y}{\partial z}\right)_x\mathrm{d}z\\ \mathrm{d}z&=\left(\frac{\partial z}{\partial x}\right)_y\mathrm{d}x+\left(\frac{\partial z}{\partial y}\right)_x\mathrm{d}y\end{aligned}\tag{9.6.310}$$

By inserting $\mathrm{d}y$ in $\mathrm{d}x$:

$$\begin{aligned}\mathrm{d}x&=\left(\frac{\partial x}{\partial y}\right)_z\left(\left(\frac{\partial y}{\partial x}\right)_z\mathrm{d}x+\left(\frac{\partial y}{\partial z}\right)_x\mathrm{d}z\right)+\left(\frac{\partial x}{\partial z}\right)_y\mathrm{d}z\\ &=\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial x}\right)_z\mathrm{d}x\left(\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x+\left(\frac{\partial x}{\partial z}\right)_y\right)\mathrm{d}z\end{aligned}\tag{9.6.311}$$

or also:

$$\left[\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial x}\right)_z-1\right]\mathrm{d}x+\left(\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x+\left(\frac{\partial x}{\partial z}\right)_y\right)\mathrm{d}z=0\tag{9.6.312}$$

as the terms in parenthesis are functions and that $\mathrm{d}x$ and $\mathrm{d}z$ are by cons arbitrary, the only solution to this relation is:

$$\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial x}\right)_z-1=0\qquad\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x+\left(\frac{\partial x}{\partial z}\right)_y=0\tag{9.6.313}$$

Multiplying the second relation by $(\partial z/\partial x)_y$:

$$\left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x+\left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial z}\right)_y=0\tag{9.6.314}$$

Then we get after simplification:

$$\left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x+1=0\tag{9.6.315}$$

Let us now turn to the facts. Let us recall the fundamental Gibbs' equation:

$$\mathrm{d}U=T\mathrm{d}S-P\mathrm{d}V\tag{9.6.316}$$

relation very useful in fluids where the pressure is constant and where the heat change is made by that of entropy. And the relation defining the enthalpy:

$$H=U+PV\tag{9.6.317}$$

from which will modify the differential:

$$\mathrm{d}H=\mathrm{d}U+V\mathrm{d}P+P\mathrm{d}V\tag{9.6.318}$$

by injecting in it (first principle):

$$\mathrm{d}U=\delta Q-P\mathrm{d}V \tag{9.6.319}$$

we have (notice that the transformation is isobaric and that the enthalpy change then represents only the amount of heat received by the closed system):

$$\mathrm{d}H=\delta Q+V\mathrm{d}P \tag{9.6.320}$$

Thus, having just added PV to the internal energy U we do have a state function (H) where we control the pressure and the entropy as independent variables, while for U alone, we control the entropy and volume as independent variables.

So we will use the following two relations that will be helpful:

$$\begin{aligned}\mathrm{d}U&=T\mathrm{d}S-P\mathrm{d}V\\ \mathrm{d}H&=T\mathrm{d}S+V\mathrm{d}P\end{aligned} \tag{9.6.321}$$

We now introduce a new quantity named "free energy" (which is really available in the system) and will be given by the "Gibbs-Helmholtz relation":

$$\boxed{F=U-TS} \tag{9.6.322}$$

and giving simply the difference between the internal energy and the heat energy dissipated because of the entropy at a given temperature. The idea being this time to control the volume and temperature as independent variables (see just a little further below when we take the differential), which is obviously an important situation in chemistry!

We also introduce another new quantity that we name "free enthalpy" or "Gibbs energy" (which is that really available in the system) and will be given identically by:

$$\boxed{G=H-TS=U+PV-TS} \tag{9.6.323}$$

which is simply the difference between the enthalpy and the dissipated heat energy because of the entropy at a given temperature.

So we have for the free energy the differential form:

$$\mathrm{d}F=\mathrm{d}U-S\mathrm{d}T-T\mathrm{d}S \tag{9.6.324}$$

by injecting in it the first principle and the second principle:

$$\mathrm{d}F=(\delta Q-P\mathrm{d}V)-S\mathrm{d}T-T\mathrm{d}S=(T\mathrm{d}S-P\mathrm{d}V)-S\mathrm{d}T-T\mathrm{d}S=-P\mathrm{d}V-S\mathrm{d}T \tag{9.6.325}$$

Thus we see that if the transformation is isothermal $\mathrm{d}F$ reduces to the work received by the closed system (since $\mathrm{d}T$ is zero).

Similarly for the free enthalpy:

$$\mathrm{d}G=\mathrm{d}H-S\mathrm{d}T-T\mathrm{d}S \tag{9.6.326}$$

by injecting:

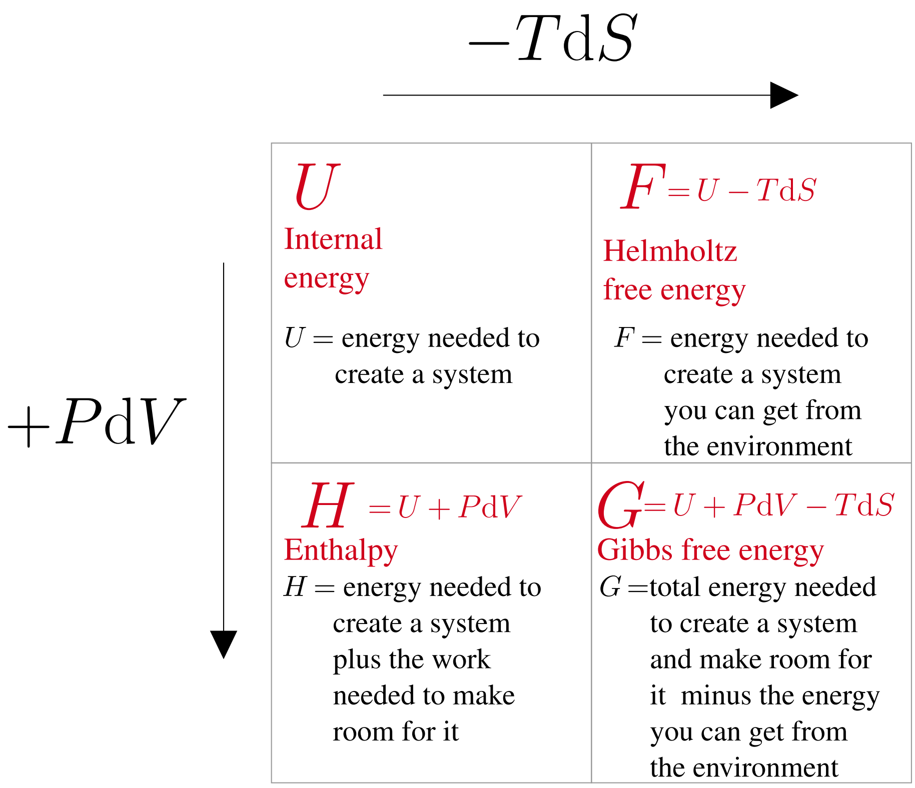
$$\mathrm{d}G=(T\mathrm{d}S+V\mathrm{d}P)-S\mathrm{d}T-T\mathrm{d}S=V\mathrm{d}P-S\mathrm{d}T \tag{9.6.327}$$

Therefore, in the case of an isobaric and isothermal transformation the free energy variation is equal zero.

So we have four relations:

$$\boxed{\begin{aligned} \mathrm{d}U &= T\mathrm{d}S - P\mathrm{d}V \\ \mathrm{d}H &= T\mathrm{d}S + V\mathrm{d}P \\ \mathrm{d}F &= -P\mathrm{d}V - S\mathrm{d}T \\ \mathrm{d}G &= V\mathrm{d}P - S\mathrm{d}T \end{aligned}} \tag{9.6.328}$$

named "Gibbs equations".



U Internal energy $U =$ energy needed to create a system	$F = U - T\mathrm{d}S$ Helmholtz free energy $F =$ energy needed to create a system you can get from the environment
$H = U + P\mathrm{d}V$ Enthalpy $H =$ energy needed to create a system plus the work needed to make room for it	$G = U + P\mathrm{d}V - T\mathrm{d}S$ Gibbs free energy $G =$total energy needed to create a system and make room for it minus the energy you can get from the environment

We notice that all these equations are of the form:

$$\mathrm{d}z = M\mathrm{d}x + N\mathrm{d}y \tag{9.6.329}$$

But, let recall that according to the Schwarz theorem (see section Differential and Integral Calculus page 1469) if $\mathrm{d}z$ is an exact total differential, then we have:

$$\left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y \tag{9.6.330}$$

This gives us immediately the four most common "Maxwell relations":

$$\boxed{\begin{aligned}\left(\frac{\partial T}{\partial V}\right)_S&=-\left(\frac{\partial P}{\partial S}\right)_V\\\left(\frac{\partial T}{\partial P}\right)_S&=-\left(\frac{\partial V}{\partial S}\right)_P\\\left(\frac{\partial P}{\partial T}\right)_V&=\left(\frac{\partial S}{\partial V}\right)_T\\\left(\frac{\partial V}{\partial T}\right)_P&=-\left(\frac{\partial S}{\partial P}\right)_T\end{aligned}} \tag{9.6.331}$$

Remark

Notice that from:

$$\left(\frac{\partial V}{\partial T}\right)_P=-\left(\frac{\partial S}{\partial P}\right)_T \tag{9.6.332}$$

we get:

$$\Delta S=-\int_{P_1}^{P_2}\left(\frac{\partial V}{\partial T}\right)_P\mathrm{d}P \tag{9.6.333}$$

where we note that T is held constant during integration over P.

And as for an ideal gas we have:

$$\left(\frac{\partial V}{\partial T}\right)_p=\frac{nR}{P} \tag{9.6.334}$$

Therefore (isothermal):

$$\Delta S=-nR\int_{P_1}^{P_2}\frac{\mathrm{d}P}{P}=-nR\ln\left(\frac{P_2}{P_1}\right) \tag{9.6.335}$$

Furthermore, by the definition of partial derivatives and the four relations:

$$\begin{aligned}\mathrm{d}U&=T\mathrm{d}S-P\mathrm{d}V\\\mathrm{d}H&=T\mathrm{d}S+V\mathrm{d}P\\\mathrm{d}F&=-P\mathrm{d}V-S\mathrm{d}T\\\mathrm{d}G&=V\mathrm{d}P-S\mathrm{d}T\end{aligned} \tag{9.6.336}$$

We get immediately:

$$\boxed{\begin{aligned}\left(\frac{\partial U}{\partial S}\right)_V&=T & \left(\frac{\partial U}{\partial V}\right)_S&=-P\\ \left(\frac{\partial H}{\partial S}\right)_V&=T & \left(\frac{\partial H}{\partial P}\right)_S&=V\\ \left(\frac{\partial F}{\partial T}\right)_V&=-S & \left(\frac{\partial F}{\partial V}\right)_T&=-P\\ \left(\frac{\partial G}{\partial T}\right)_P&=-S & \left(\frac{\partial G}{\partial P}\right)_T&=V\end{aligned}} \tag{9.6.337}$$

All these relationships are used to calculate the thermodynamic variables not directly measurable from the experimental data.

For example, from the last one:

$$\left(\frac{\partial G}{\partial P}\right)_T=V \tag{9.6.338}$$

we get immediately:

$$\Delta G=\int_{P_1}^{P_2} V\,\mathrm{d}P \tag{9.6.339}$$

and considering and ideal gas again with $V=nRT/P$, we get (at constant temperature):

$$\Delta G=nRT\int_{P_1}^{P_2}\frac{1}{P}\mathrm{d}P=nRT\ln\left(\frac{P_2}{P_1}\right) \tag{9.6.340}$$

To close the subject about the definitions of these thermodynamic variables, let us indicate that the fact of creating (defining):

$$\begin{aligned}H&=U+PV\\F&=U-TS\\G&=H-TS\end{aligned} \tag{9.6.341}$$

or in other words, that fact that for every pair X,Y of conjugated thermodynamic variables and function f we put:

$$g=f-XY \tag{9.6.342}$$

is named a "Legendre transformation" (for the mathematical details of the transformation see the section of Analytical Mechanics). This type of transformation allows to change the set of independent variables to get a set of best suited variables to the problem considered.

Now let see a relation that will be useful to use in the section of Weather and Marine!

We know that the specific heat is given by definition at constant pressure by:

$$C_P=\frac{\Delta Q}{\Delta T} \tag{9.6.343}$$

But at constant pressure, the heat variation can be written by definition with the enthalpy:

$$C_P=\left(\frac{\partial H}{\partial T}\right)_P \tag{9.6.344}$$

Now remember that the enthalpy is given by:

$$\mathrm{d}H=T\mathrm{d}S+V\mathrm{d}P \tag{9.6.345}$$

as $\mathrm{d}S$ is an exact differential, we can write it as a function of the parameters of temperature and pressure only:

$$\mathrm{d}S=\left(\frac{\partial S}{\partial T}\right)_P\mathrm{d}T+\left(\frac{\partial S}{\partial P}\right)_T\mathrm{d}P \tag{9.6.346}$$

Therefore we have:

$$\mathrm{d}H=\left[\left(\frac{\partial S}{\partial T}\right)_P\mathrm{d}T+\left(\frac{\partial S}{\partial P}\right)_T\mathrm{d}P\right]+V\mathrm{d}P=T\left(\frac{\partial S}{\partial T}\right)_P\mathrm{d}T+\left[T\left(\frac{\partial S}{\partial P}\right)_T+V\right]\mathrm{d}P \tag{9.6.347}$$

As by the way $\mathrm{d}H$ is an exact differential, we can also write it in function of the parameters of temperature and pressure only:

$$\mathrm{d}H=\left(\frac{\partial H}{\partial T}\right)_P\mathrm{d}T+\left(\frac{\partial H}{\partial P}\right)_T\mathrm{d}P=C_P\mathrm{d}T+\left(\frac{\partial H}{\partial P}\right)_T\mathrm{d}P \tag{9.6.348}$$

We have then the two relations to identify:

$$\begin{aligned}\mathrm{d}H&=T\left(\frac{\partial S}{\partial T}\right)_P\mathrm{d}T+\left[T\left(\frac{\partial S}{\partial P}\right)_T+V\right]\mathrm{d}P\\ \mathrm{d}H&=C_P\mathrm{d}T+\left(\frac{\partial H}{\partial P}\right)_T\mathrm{d}P\end{aligned} \tag{9.6.349}$$

Remark

If the Enthalpy of a gas depends only of the temperature (quite unrealistic), the last relation above reduces to:

$$\mathrm{d}=C_P\mathrm{d}T \tag{9.6.350}$$

This is named the "second Joule's law".

It comes therefore:

$$\boxed{T\left(\frac{\partial S}{\partial T}\right)_P=C_P\qquad T\left(\frac{\partial S}{\partial P}\right)_T+V=\left(\frac{\partial H}{\partial P}\right)_T} \tag{9.6.351}$$

9.6.11 Continuity Equation

A continuity equation in physics is an equation that describes the transport of some quantity. It is particularly simple and particularly powerful when applied to a conserved quantity, but it can be generalized to apply to any extensive quantity. Since mass, energy, momentum, electric charge and other natural quantities are conserved under their respective appropriate conditions, a variety of physical phenomena may be described using continuity equations.

Continuity equations are a stronger, local form of conservation laws. For example, a weak version of the law of conservation of energy states that energy can neither be created nor destroyed i.e., the total amount of energy is fixed[26]. This statement does not immediately rule out the possibility that energy could disappear from a field in Canada while simultaneously appearing in a room in Indonesia. A stronger statement is that energy is locally conserved: Energy can neither be created nor destroyed, nor can it "teleport" from one place to another - it can only move by a continuous flow. A continuity equation is the mathematical way to express this kind of statement. For example, the continuity equation for electric charge states that the amount of electric charge at any point can only change by the amount of electric current flowing into or out of that point.

Continuity equations more generally can include "source" and "sink" terms, which allow them to describe quantities that are often but not always conserved, such as the density of a molecular species which can be generated or destroyed by chemical reactions. In an everyday example, there is a continuity equation for the number of people alive; it has a "source term" to account for people being born, and a "sink term" to account for people dying. Any continuity equation can be expressed in an "integral form" (in terms of a flux integral), which applies to any finite region, or in a "differential form" (in terms of the divergence operator) which applies at a point. Continuity equations underlie more specific transport equations such as the convection–diffusion equation, Boltzmann transport equation, and Navier–Stokes equations.

Now let us consider generally an open system, limited by any boundary Ω (deformable or not) and animated by any movement (moving or stationary) relative to a reference frame considered as fixed.

This system is shown in the figure below, is capable of transferring energy (or mass, or electric charges, etc.) between itself and the outside. This system may be inertial or not.

Given an extensive quantity A (like mass or charge). The corresponding quantitative magnitude will be denoted by a (it can express for example the isotropy or anisotropy of the system).

---

[26] It is strongly advice that the reader remembers the situation where this principle doesn't apply as seen during our study of Noether's theorem!

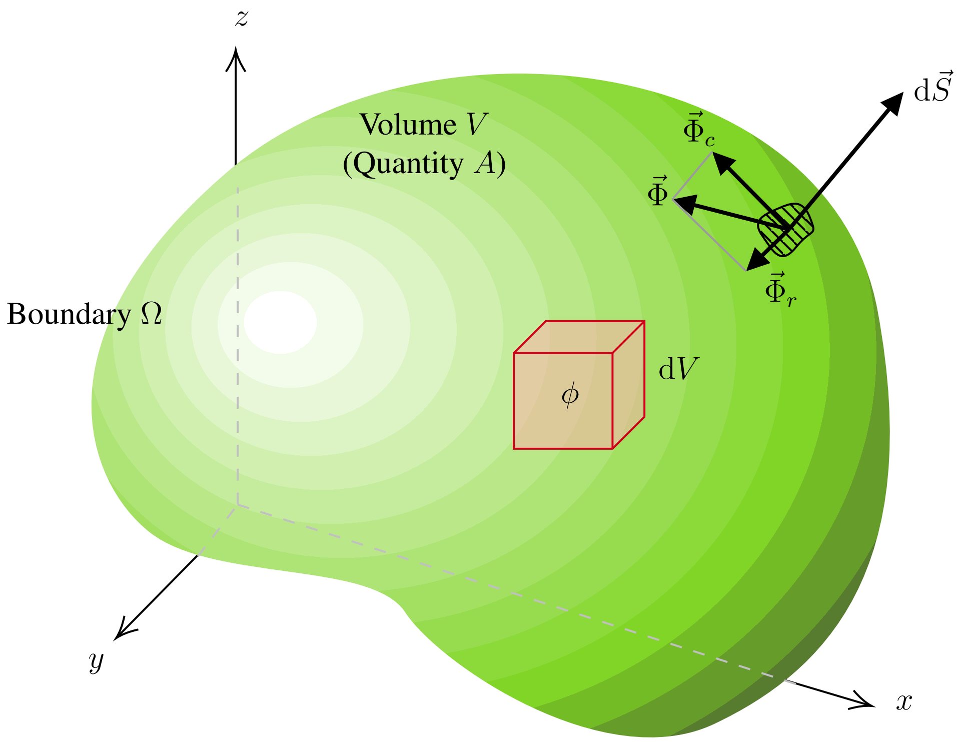


Figure 9.170: **Open system in translation or not in a repository and transferring energy**

In general, the value of A within the system is, at any instant:

$$A = \iiint_V \rho a \mathrm{d}V \qquad (9.6.352)$$

ρ being the density of an extensive quantity A.

The spatial variation rate of A is given by the derivative $\mathrm{d}A/\mathrm{d}t$. The causes of variations of A can be related to two different phenomena: the flows and the sources or sinks.

Counting positively what enters the system, the flow of A through the boundary Ω is given by the surface integral:

in which we define:

- $\vec{\Phi}$ as the total surfacic flux vector (or the "current density vector") relatively to A
- $\mathrm{d}\vec{S}$ as the boundary element, expressed by a vector normal to the surface and directed towards the outside

$$\iint_S \vec{\Phi} \circ \mathrm{d}S \qquad (9.6.353)$$

Let us notice that, at the contrary to the usual meaning in physics, the concept of flow Φ already contains here the derivation with respect to time. Furthermore, to simplify the text, the expression "surfacic vector flow" is reduced here the term "flow" in all that follows.

This flow can be split into multiple flows, according to the relation:

$$\vec{\Phi}=\vec{\Phi}_a-\vec{\Phi}_d+\vec{\Phi}_c=\vec{\Phi}_r+\vec{\Phi}_c \qquad (9.6.354)$$

where:

- The term $\vec{\Phi}_a$ is a flow by absolute translation, characterizing a flow from a fluid flow. We have then relation:

  $$\vec{\Phi}_a=\rho a\vec{v}_a \qquad (9.6.355)$$

  where $\vec{v}_a$ the absolute velocity of a fluid particle with respect to the fixed reference frame.

- The term $\vec{\Phi}$ is an apparent displacement flow, involved only when the boundary Ω moves. We have the relation:

  $$\vec{\Phi}_d=\rho a\vec{v}_d \qquad (9.6.356)$$

  where $\vec{v}_d$ is apparent speed of movement of a point on the boundary Ω, relatively to the fixed reference frame.

- The term $\vec{\Phi}_c$ is the total flow by conduction, characterizing a flow linked to a transfer phenomenon at the microscopic level, without fluid movement (eg heat conduction, electrical conduction, mechanical work).

Under the principle of composition of velocities (absolute speed is the sum of the relative speed and its apparent speed), we have:

$$\vec{v_r}=\vec{v}_a-\vec{v}_d \qquad (9.6.357)$$

and therefore:

$$\vec{\Phi}_r=\vec{\Phi}_a-\vec{\Phi}_d \qquad (9.6.358)$$

The corresponding flow of A is then given by (under the assumption that a is given in unit of our quantity of interest by unit mass):

$$\iint_{S_f} a\frac{\mathrm{d}M}{\mathrm{d}t}=\iint_{S_f}\vec{\Phi}_r\circ\mathrm{d}\vec{S} \qquad (9.6.359)$$

where S_f denotes the boundary portion through which the mass flow occurs.

If we count positively the effect of a source, the rate of increase of A is given by:

$$\iiint_V \phi\mathrm{d}V \qquad (9.6.360)$$

where ϕ is the volume flow from a source of A.

Taking into account both flows and sources, we have the spatial rate variation of A:

$$\frac{\mathrm{d}A}{\mathrm{d}t}=\iint_S a\mathrm{d}M+\iint_S\vec{\Phi}_c\circ\mathrm{d}\vec{S}+\iint_V\phi\mathrm{d}V \qquad (9.6.361)$$

The spatial balance of A is finally expressed by the relation: In the particular case of a system in continuous operation (eg in the case of a flowing fluid or a solid in which we can observe a thermal conduction, an electrical conduction, a nuclear reaction, etc.), all local variables are constant at any point of the system. If, furthermore, we choose a boundary Ω dimensionally stable, it is possible to reason with respect to a reference frame linked to the considered system. We then have, at any fixed point of the system relative to this reference frame:

$$\rho = c^{te} \qquad a = c^{te} \qquad V = c^{te} \tag{9.6.362}$$

It results for the whole system:

$$A = c^{te} \Leftrightarrow \frac{\mathrm{d}A}{\mathrm{d}t} = 0 \tag{9.6.363}$$

So in the case of a steady system, with a dimensionally stable boundary Ω, linked to the system, the spatial variation rate of any extensive scalar quantity is zero.

The spatial variation rate of A starting (for recall) from:

$$A = \iiint_V \rho a \mathrm{d}V \tag{9.6.364}$$

given by:

$$\Phi = \frac{\mathrm{d}A}{\mathrm{d}t} = \iiint_V \rho a \mathrm{d}V = \iiint_V \frac{\partial(\rho a)}{\partial t}\mathrm{d}V + \iiint_V \rho a \frac{\partial}{\partial t}(\mathrm{d}V) \tag{9.6.365}$$

The elementary variation in the volume V is due to the displacement (in the sense of the deformation!) of the boundary Ω, so that:

$$\partial(\mathrm{d}V) = \mathrm{d}(\mathrm{d}V) = (\mathrm{d}\vec{S} \circ \vec{v}_d)\mathrm{d}t \tag{9.6.366}$$

Therefore we can write that:

$$\iiint_V \rho a \frac{\partial}{\partial t}(\mathrm{d}V) = \iiint_V \rho a \frac{\partial}{\partial t}(\mathrm{d}\vec{S} \circ \vec{v}_d)\mathrm{d}t = \iiint_V \vec{\Phi}_d \circ \mathrm{d}\vec{S} \tag{9.6.367}$$

Hence:

$$\frac{\mathrm{d}A}{\mathrm{d}t} = \iiint_V \frac{\partial(\rho a)}{\partial t}\mathrm{d}V + \iiint_V \vec{\Phi}_d \circ \mathrm{d}\vec{S} \tag{9.6.368}$$

Considering the flow of sources and wells, we have for the first term:

$$\iiint_V \frac{\partial(\rho a)}{\partial t}\mathrm{d}V = \iint_S \vec{\Phi} \circ \mathrm{d}\vec{S} + \iiint_V \phi \mathrm{d}V = \iint_S (\vec{\Phi}_a + \vec{\Phi}_c) \circ \mathrm{d}\vec{S} + \iiint_V \phi \mathrm{d}V \tag{9.6.369}$$

The Gauss-Ostrogradsky theorem (see section Vector Calculus page 1882) will allow us to write the surface integral into a volume integral, and grouping all terms under the same integral sign, we get immediately:

$$\iiint_V \left[\frac{\partial(\rho a)}{\partial t} - \vec{\nabla} \circ (\vec{\Phi}_a + \vec{\Phi}_c) - \phi\right] \mathrm{d}V = 0 \tag{9.6.370}$$

As the limits of integration (boundary Ω) are arbitrary, the expression in brackets is identically zero such that we are led to write:

$$\frac{\partial(\rho a)}{\partial t}-\vec{\nabla}\circ(\vec{\Phi}_a+\vec{\Phi}_c)-\phi \tag{9.6.371}$$

Let us consider now the special case where the scalar extensive quantity is the mass M, then we have:

$$A=M=\iiint_V \rho \mathrm{d}V \tag{9.6.372}$$

with $a=1$.

Since the mass is not likely to be transferred by a conduction phenomenon (in a classic case (non-quantum)) we have $\vec{\Phi}_c$ that is zero (in many text books even when there is conduction we consider $\vec{\Phi}_c \ll \vec{\Phi}_a$...). Since the mass is conservative, there is no source or well so that ϕ is also zero.

We have therefore:

$$\frac{\partial(\rho a)}{\partial t}-\vec{\nabla}\circ(\vec{\Phi}_a+\vec{\Phi}_c)-\phi=\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0 \tag{9.6.373}$$

Since the mass is not likely to be transferred by a conduction phenomenon (in a classic case (non-quantum)) we have $\vec{\Phi}_c$ that is zero (in many text books even when there is conduction we consider $\vec{\Phi}_c \ll \vec{\Phi}_a$...). Since the mass is conservative, there is no source or well so that ϕ is also zero.

We have therefore:

$$\frac{\partial(\rho a)}{\partial t}-\vec{\nabla}\circ(\vec{\Phi}_a+\vec{\Phi}_c)-\phi=\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0 \tag{9.6.374}$$

The relation:

$$\boxed{\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0} \tag{9.6.375}$$

is named "continuity equation" or "(mass) conservation equation".

The "$-$" sign is here because we defined the incoming flow as positive. It is possible that in the literature as well as in this textbook, you find a "$+$" instead of that sign such that:

$$\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0 \tag{9.6.376}$$

Thus, a fluid element in a divergent flow field will experience a reduction in density!

There is another much more common form in which we can find the continuity equation. The reader will have noticed that the term $\rho\vec{v}_a$ has units of a massic surface current density $[\mathrm{kg}\cdot\mathrm{m}^{-2}\cdot\mathrm{s}^{-1}]$ which bring us in analogy with electronics (see section Electrokinetics page 4229) to write:

$$(\rho\vec{v}_a)=\vec{j} \tag{9.6.377}$$

Which leads to the following form of the continuity equation:

$$\boxed{\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ\vec{j}=0} \tag{9.6.378}$$

9.6.11.1 Heat Equation

Let us apply this result to the diffusion of heat that as important applications in many fields of study (wave mechanics, Schrödinger equation in quantum physics, thermodynamics, fluid dynamics, Black & Scholes equation in finance, for resistance study in electrokinetics, electromagnetic wave propagation in a medium, in chemistry for some reactions, in nuclear neutronics, etc.) and there is considerable literature on the various solutions of this differential equation of the second order. In the section of Functional Analysis will prove how to solve this equation with the Fourier transform and the Laplace transform.

As for the conservation of mass equation, we can write for the heat in the absence of sources:

$$\boxed{\frac{\partial q}{\partial t}+\vec{\nabla}\circ\vec{\Phi}_q=0} \qquad (9.6.379)$$

where q is the amount of heat per unit volume (do not forget it otherwise we would have taken a capital Q!) and $\vec{\Phi}_q$ is the heat flow whose incoming quantity was defined as negative.

A temperature variation causing a variation in the quantity of heat is defined as a first approximation by the following physical law (this follows from the definition of the specific massic heat...):

$$\mathrm{d}q=\rho c_P\mathrm{d}T \qquad (9.6.380)$$

where ρ is the density of matter and c_P is the specific heat capacity. Or equivalently (since in Thermodynamics, as we have already mentioned it, lower case is reported to the mass):

$$\mathrm{d}Q=\rho C_P\mathrm{d}T \qquad (9.6.381)$$

So the heat equation is a parabolic partial differential equation that describes the distribution of heat (or variation in temperature) in a given region over time.

The heat flux being trivially induced by spatial temperature difference, we obtain the "Fourier law" which expresses the heat flow in proportion to the spatial temperature gradient:

$$\boxed{\vec{\Phi}_q=-\kappa\vec{\nabla}T} \qquad (9.6.382)$$

The "$-$" sign is simply due to the fact the heat flow goes from the warmer to the colder and κ is the "heat transmission coefficient" expressing the "thermal conductivity" of the material dependent on its atomic and structural macroscopic properties. In the 121st century (holocene calendar) where climate change is quite a big issue, the research for good insulating material (low thermal conductivity materials) to keep houses and buildings warm in Winter (in the purpose to decrease energy loss by radiation) is an important area of research.

Material	**Thermal Conductivity** $\left[\mathrm{W}\cdot\mathrm{m}^{-1}\cdot\mathrm{K}^{-1}\right]$
Glass wool	0.04
Rock wool	0.045
Concrete, light	0.42
Cellulose	0.039
PVC	0.19
Cement	1.01
Cement mortar	1.73
Granite	$1.7-4$
Oak tree	0.17
Marble stone	$2.08-2.94$

Table 9.30: **Some Thermal conductivities**

Or for some ceramics:

Material Name	**Melting Point** [°**C**]	**Density** [**g** $\cdot$ **cm**$^{-3}$]	**Specific Heat** [**J** $\cdot$ **kg**$^{-1}$ $\cdot$ °**C**$^{-1}$]	**Linear Coefficient of expansion** 10^{-6} [°**C**$^{-1}$]	**Thermal Conductivity** [**W** $\cdot$ **m**$^{-1}$ $\cdot$ °**C**$^{-1}$]

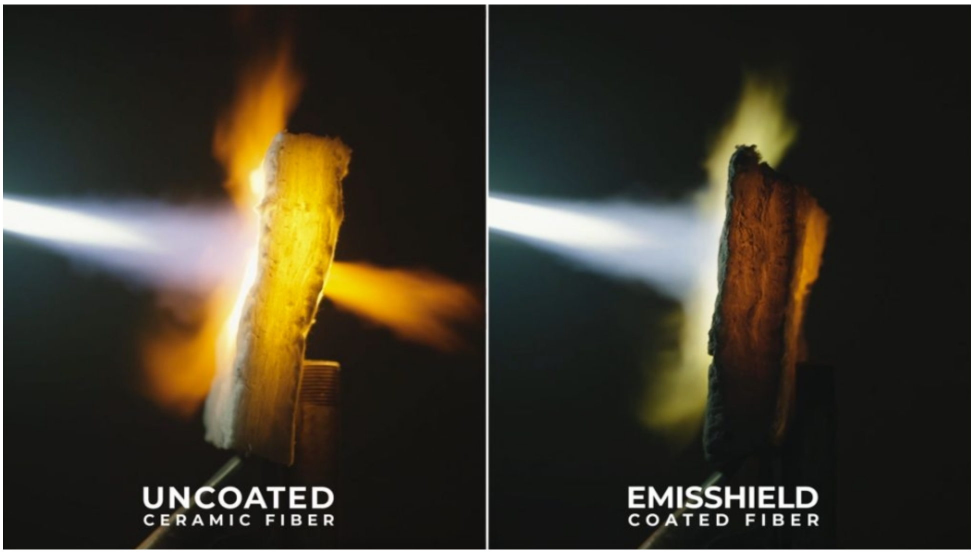
Table 9.31: **Thermal conductivities and specific heat of some ceramics**

As we can see above, Ceramic is incredibly resistant, and it can withstand temperatures of $4,000$ degrees Celsius. Ceramic coating (like Emmishield™ Wessex's PCCM[27] product) that can withstand up to $2,000$ degrees Celsius is often used on spatial applications to increase the resistance to heat.

---

[27] protective coating for ceramic materials



Remark

AVCOAT 5026-39 is a NASA code (see [386]) for a specific ablative heat shield material developed by Avco (acquired by Textron in 1984). It is an epoxy novolac resin with special additives in a fiberglass honeycomb matrix. In fabrication, the empty honeycomb is bonded to the primary structure and the resin is gunned into each cell individually. AVCOAT was used for the heat shield on NASA's Apollo command module (which landed astronauts on the Moon between 11969 and 11972 according to holocene calendar). It has a density of $0.51\;[\text{g}\cdot\text{cm}^{-3}]$, it has a thermal conductivity of $0.16442\;[\text{W}\cdot\text{m}^{-1}]$ at $400\;[\text{K}]$, a melting point of $2,760\;[\text{K}]$ and a linear coefficient of expansion of $0.16442\cdot 10^{-2}\;[^\circ\text{C}^{-1}]$ at $400\;[\text{K}]$.

We find more often in practice this relation in the following form in the one-dimensional case (we will do a small practical example further with this form of writing):

$$q=\Phi_q S=-\kappa S\frac{\mathrm{d}T}{\mathrm{d}x}\cong-\kappa\frac{\Delta T}{\Delta x}\qquad(9.6.383)$$

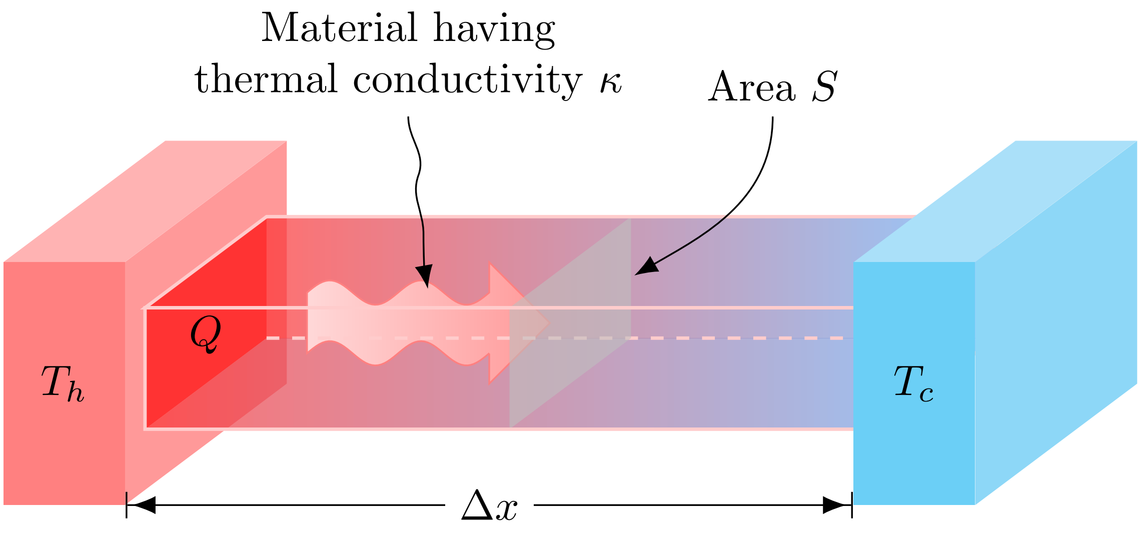


Figure 9.171: Heat conduction occurs through any material, represented here by a rectangular bar

By inserting the two prior previous relations in the heat conservation equation, we have:

$$\frac{\rho C_P \mathrm{d}T}{\partial t}+\vec{\nabla}\circ(-\kappa\vec{\nabla}T)=0 \tag{9.6.384}$$

after rearranging a little bit:

$$\frac{\partial T}{\partial t}-\frac{\kappa}{\rho c_P}\vec{\nabla}\circ(\vec{\nabla}T)=0 \tag{9.6.385}$$

More aesthetically and more generally (but still in one dimension), we find it in the condensed form of the "heat diffusion equation" or more simply named "heat equation":

$$\boxed{\frac{\partial T}{\partial t}-D_T\frac{\partial^2 T}{\partial x^2}=0} \tag{9.6.386}$$

where the coefficient of proportionality is named in the context of heat study: "thermal diffusivity":

$$D_T=\frac{\kappa}{c_P\rho} \tag{9.6.387}$$

It is possible to prove its microscopic origin as we will prove it further below.

We must always pay attention to the units of κ following that we work the with the massic specific heat capacity c_P or the heat capacity C_P in the denominator!

So under completely explicit form, we have in one dimension:

$$\frac{\partial T(x,t)}{\partial t}-\frac{\kappa}{\rho c_P}\frac{\partial^2 T(x,t)}{\partial x^2}=0 \tag{9.6.388}$$

Remarks

R1. We will see again this equation in the section of Theoretical Computing to introduce the reader to the concept of solving differential equations using the finite element method with a simple example of resolution using Microsoft® Excel® or in the MATLAB® companion book.

R2. It is by studying this equation that Fourier introduced the series and transformation that bear his name, and which became so important in the study of phenomena of propagation / diffusion.

R3. Often practitioners write:

$$q = -\kappa S\frac{\Delta T}{\Delta x} = -\frac{\Delta T}{\dfrac{\Delta x}{\kappa S}} = -\frac{\Delta T}{R_{\text{th.}}} \qquad (9.6.389)$$

and thus we can introduce the concept of "thermal resistance $R_{\text{th.}}$" in the denominator. In short nothing spectacular but of frequent use.

Let us insist that all relations of the type:

$$\frac{\partial u}{\partial t} - D\frac{\partial^2 u}{\partial x^2} = 0 \qquad (9.6.390)$$

are named "diffusion equations" of physical parameter D and is a parabolic partial differential equation (see section Differential and Integral Calculus page 1625). We will immediately see how to solve this differential partial equation using and this will lead us to understand why Fourier introduced the famous transformations that bear today his name. But let us remind the reader that we find this partial differential equation in multiple contexts.

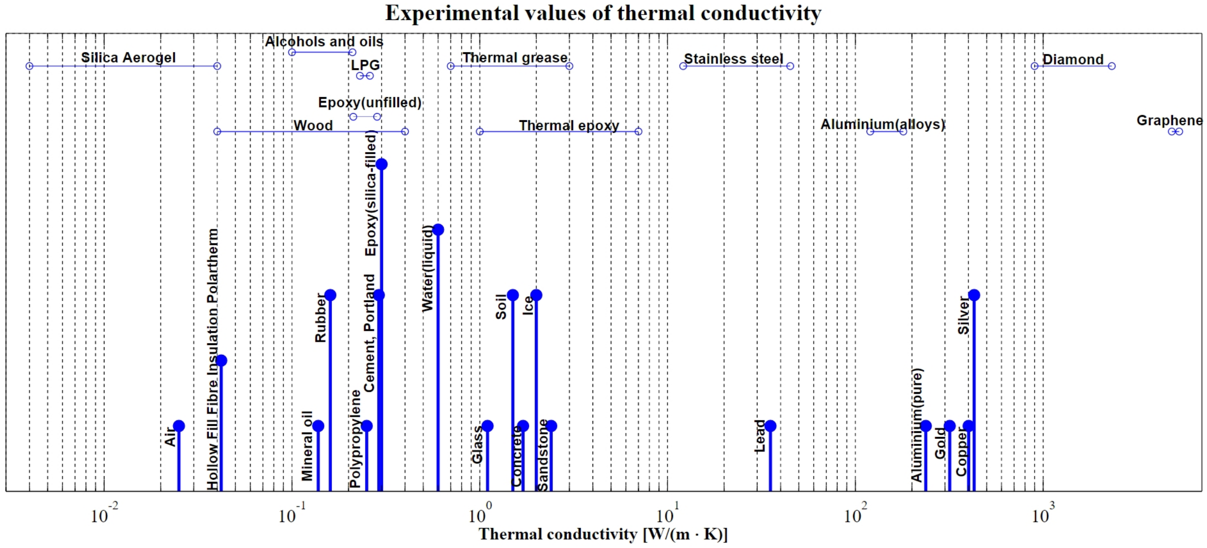

Figure 9.172: Thermal conductivity values for various materials (source: Wikipedia)

✍**Examples:**

E1. A parallelepiped made of steel (having a thermal conductivity of 17 $[\mathrm{W}\cdot\mathrm{m}^{-1}\cdot\mathrm{K}^{-1}]$) has one side thereof maintained at 331.15 $[\mathrm{K}]$ and the other at 297.15 $[\mathrm{K}]$, both faces being separated by 1 $[\mathrm{cm}]$ and having a surface 1 $[\mathrm{m}^2]$: Assuming a situation at equilibrium the heat transfer is given by:

$$q=-\kappa S\frac{\Delta T}{\Delta x}=-17.1\left(\frac{331.15-297.15}{0-0.01}\right)=34\,[\mathrm{W}] \tag{9.6.391}$$

E2. For a cylindrical tube carrying a heated fluid (very important case in practice) we want to determine the amount of heat exchanged per unit of time with the outside environment. Knowing that the surface in contact with the fluid (with inner radius r_i) is not the same that the one in contact with the outside environment (external radius r_e) we can not simply calculate ratio of the temperature differences with the distance between the two surfaces. Therefore we have to proceed as following:

$$\begin{aligned}q&=-\kappa S\frac{\mathrm{d}T}{\mathrm{d}r}=-\kappa 2\pi r\frac{\Delta T}{\mathrm{d}r}=-\kappa 2\pi\frac{\Delta T}{\dfrac{1}{r}\mathrm{d}r}=-\kappa 2\pi\frac{\Delta T}{\dfrac{1}{r}\mathrm{d}r}=-\kappa 2\pi\frac{T_e-T_i}{\displaystyle\int_{r_i}^{r_e}\frac{1}{r}\mathrm{d}r}\\&=\kappa 2\pi\frac{T_i-T_e}{\ln(r)|_{r_i}^{r_e}}=\kappa 2\pi\frac{T_i-T_e}{\ln(r_e)-\ln(r_i)}=\kappa 2\pi\frac{T_i-T_e}{\ln\left(\dfrac{r_e}{r_i}\right)}\end{aligned} \tag{9.6.392}$$

Let us solve the general form of the diffusion equation without sources:

$$\frac{\partial u}{\partial t}=D\frac{\partial^2 u}{\partial x^2} \tag{9.6.393}$$

To solve this differential equation of the second order, we will use the method of separation of variables (see section Differential and Integral Calculus page 1617) rather than attacking directly by Fourier transforms (which requires as prior the proof of the dominated convergence theorem which makes me horror).

We assume therefore using the separation of variables method that:

$$u(x,t)=X(x)T(t) \tag{9.6.394}$$

And where $T(t)$ by the principle of the second law of thermodynamics must decrease as t increases.

We get immediately:

$$\begin{aligned}\frac{\partial u}{\partial t}&=\frac{\partial X(x)\partial T(t)}{\partial t}=\frac{\partial X(x)}{\partial t}T(t)+X(x)\frac{\partial T(t)}{\partial t}=X\frac{\partial T}{\partial t}\\\frac{\partial^2 u}{\partial x^2}&=\frac{\partial^2 X(x)\partial T(t)}{\partial x^2}=\frac{\partial^2 X(x)}{\partial x^2}T(t)+X(x)\frac{\partial^2 T(t)}{\partial x^2}=T\frac{\partial^2 X}{\partial x^2}\end{aligned} \tag{9.6.395}$$

hence the diffusion equation:

$$\frac{\partial u}{\partial t}=D\frac{\partial^2 u}{\partial x^2}\Rightarrow X\frac{\partial T}{\partial t}=DT\frac{\partial^2 X}{\partial x^2} \tag{9.6.396}$$

what rearranged and condensed is also written:

$$\frac{1}{D}\frac{T'}{T}=\frac{X''}{X} \tag{9.6.397}$$

Which can be written by assuming that each of the expressions on the left and right of equality are assimilated to functions:

$$G(t)=F(x) \tag{9.6.398}$$

so that equality is true for all t and x, the functions G and F functions must be constant. So we have the right to write:

$$\frac{1}{D}\frac{T'}{T}=\frac{X''}{X}=c^{te}=-\lambda^2 \tag{9.6.399}$$

The fact to write the constant negative and squared is a simple anticipation of the result historically already known... But to understand why the constant is necessarily negative, just think that T' is necessarily negative (the temperature of a isolated system will not rise alone but naturally decrease based on the principle of entropy) and as D and T are positive then verbatim ...

What gives us the system of two independent differential equations of the second order:

$$\begin{aligned}X''+\lambda^2X&=0\\T'+\lambda^2DT&=0\end{aligned} \tag{9.6.400}$$

That some text books write as following:

$$\begin{aligned}X_{xx}+\lambda^2X&=0\\T_t+\lambda^2DT&=0\end{aligned} \tag{9.6.401}$$

We solve the second differential equation first:

$$\frac{1}{T(t)}\frac{\partial T(t)}{\partial t}=-\lambda^2D\Rightarrow \ln(T(t))=-\lambda^2Dt+c^{te} \tag{9.6.402}$$

Therefore:

$$T(t)=e^{-\lambda^2Dt+c^{te}}=e^{c^{te}}e^{-\lambda^2Dt}=A(\lambda)e^{-\lambda^2Dt} \tag{9.6.403}$$

And for the first differential equation:

$$\frac{\partial X(x)^2}{\partial x^2}+\lambda^2X(x)=0 \tag{9.6.404}$$

We then have the characteristic polynomial:

$$r^2+\lambda^2=0 \tag{9.6.405}$$

Thus the roots:

$$r_{1,2}=\pm\sqrt{-\lambda^2}=\pm\mathrm{i}\lambda \tag{9.6.406}$$

So as the discriminant is negative (see section Differential and Integral Calculus page 1611) we have:

$$X(x)=A'(\lambda)e^{\mathrm{i}(\lambda x+c^{te})}+B'(\lambda)e^{-\mathrm{i}(\lambda x+c^{te})} \tag{9.6.407}$$

Therefore:

$$\begin{aligned}u(x,t)&=T(t)X(x)=A(\lambda)e^{-\lambda^2Dt}\left(A'(\lambda)e^{\mathrm{i}(\lambda x+c^{te})}+B'(\lambda)e^{-\mathrm{i}(\lambda x+c^{te})}\right)\\&=\left(C_1(\lambda)e^{\mathrm{i}(\lambda x+c^{te})}+C_2(\lambda)e^{-\mathrm{i}(\lambda x+c^{te})}\right)e^{-\lambda^2Dt}\end{aligned} \tag{9.6.408}$$

If we move the exponential of the constants in factors such as:

$$\begin{aligned}C_1(\lambda)e^{\mathrm{i}c^{te}}&={C'}_1(\lambda)\\C_2(\lambda)e^{-\mathrm{i}c^{te}}&={C'}_2(\lambda)\end{aligned} \tag{9.6.409}$$

this simplifies the expression:

$$u(x,t)=\left({C'}_1(\lambda)e^{\mathrm{i}\lambda x}+{C'}_2(\lambda)e^{-\mathrm{i}\lambda x}\right)e^{-\lambda^2Dt} \tag{9.6.410}$$

whose coefficients will be determined case by case by the initial conditions of which the most famous school cases and subject to an extensive literature are:

- Dirichlet boundaries conditions:

$$x=(0,L)\qquad u(0,t)=0=u(L,t) \tag{9.6.411}$$

- Neumann boundaries conditions:

$$x=(0,L)\qquad \frac{\mathrm{d}u}{\mathrm{d}x}(0,t)=0=\frac{\mathrm{d}u}{\mathrm{d}x}(L,t) \tag{9.6.412}$$

Since for each possible value of λ we get a solution, it appears that doing the sum of all these solutions, we get the general solution. We therefore finite Fourier series:

$$u(x,t)=\sum_{\lambda}\left({C'}_1e^{\mathrm{i}\lambda x}+{C'}_2(\lambda)e^{-\mathrm{i}\lambda x}\right)e^{-\lambda^2Dt} \tag{9.6.413}$$

because of the presence of the square λ in the temporal exponential in factor (right) of the parenthesis, if we sum over all the λ from $-\infty,+\infty$ then the sum of all terms of the parenthesis cancel for each pair of positive and negative λ of the same value. Then we must summon only on the semi-positive infinite line (either left or right it does not matter) if we do not want the result to be zero. If we choose arbitrarily the positive infinite line, then we get:

$$u(x,t)=\sum_{\lambda=0}^{+\infty}\left({C'}_1(\lambda)e^{\mathrm{i}\lambda x}+{C'}_2(\lambda)e^{-\mathrm{i}\lambda x}\right)e^{-\lambda^2Dt} \tag{9.6.414}$$

Nothing now prevents us from taking out a factor λ of the constant $C'_1(\lambda)$, $C'_2(\lambda)$, the only effect it will have is to change their normalisation given by the initial conditions .. Then we have:

$$\begin{aligned} u(x,t) &= \sum_{\lambda=0}^{+\infty} \left(\lambda C''_1(\lambda)e^{\mathrm{i}\lambda x} + \lambda C''_2(\lambda)e^{-\mathrm{i}\lambda x}\right) e^{-\lambda^2 Dt} \\ &= \sum_{\lambda=0}^{+\infty} \left(C''_1(\lambda)e^{\mathrm{i}\lambda x} + C''_2(\lambda)e^{-\mathrm{i}\lambda x}\right) e^{-\lambda^2 Dt}\lambda \end{aligned} \tag{9.6.415}$$

As λ is a continuous real parameter (and also positive) in by making it tend to zero the sum can be changed into an integral (doing this in the physicist way...) and then we get:

$$u(x,t) = \int\limits_0^{+\infty} C''_1(\lambda)e^{-\lambda^2 Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda + \int\limits_0^{+\infty} C''_2(\lambda)e^{-\lambda^2 Dt-\mathrm{i}\lambda x}\mathrm{d}\lambda \tag{9.6.416}$$

And making a change of variable for the second integral, we have:

$$\begin{aligned} u(x,t) &= \int\limits_0^{+\infty} C''_1(\lambda)e^{-\lambda^2 Dt+\mathrm{i}(\lambda x+c^{te})}\mathrm{d}\lambda - \int\limits_0^{-\infty} C''_2(-\lambda)e^{-\lambda^2 Dt-\mathrm{i}(-\lambda x+c^{te})}\mathrm{d}t \\ &= \int\limits_0^{+\infty} C''_1(\lambda)e^{-\lambda^2 Dt+\mathrm{i}(\lambda x+c^{te})}\mathrm{d}\lambda + \int\limits_{-\infty}^{0} C''_2(-\lambda)e^{-\lambda^2 Dt+\mathrm{i}(\lambda x-c^{te}}\mathrm{d}\lambda \end{aligned} \tag{9.6.417}$$

By grouping the constants, we have:

$$\boxed{u(x,t) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{+\infty} F(\lambda)e^{-\lambda^2 Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda} \tag{9.6.418}$$

with:

$$\begin{aligned} F(\lambda) &= \sqrt{2\pi}C''_1(\lambda) \quad \text{for } \lambda > 0 \\ F(\lambda) &= \sqrt{2\pi}C''_2(\lambda) \quad \text{for } \lambda < 0 \end{aligned} \tag{9.6.419}$$

We have now something interesting! At the time $t=0$, the previous integral is written:

$$u(x,t) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{+\infty} F(\lambda)e^{\mathrm{i}\lambda x}\mathrm{d}\lambda \tag{9.6.420}$$

and changing the notation for the parameter λ and the notation for x, we have:

$$u(x,t) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{+\infty} F(\omega)e^{\mathrm{i}\omega x}\mathrm{d}\lambda \tag{9.6.421}$$

And so what???? are you perhaps thinking just now...? Well as we saw in our study of the Fourier transforms (see section Sequences and Series page 1758) the latter relation is an inverse Fourier transform which is an infinite sum of real trigonometric functions! This means that any function describing the temperature distribution at time t zero for an infinitely long bar and whose ends at the same time tend to zero (thus implicitly it is a function of infinite period) such that:

$$\begin{gathered}u(x,0)=f(x)\\ f(\pm\infty)\rightarrow 0\end{gathered}\tag{9.6.422}$$

Satisfies the equation of Heat as an infinite trigonometric series. Let us return to our initial notation:

$$u(x,t)=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}F(\lambda)e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda\tag{9.6.423}$$

As a recall of the section Sequences and Series (with the notation adapted here) we have by applying the inverse Fourier transform:

$$u(x,0)=\mathcal{F}^{-1}(F(\lambda))(x)=f(x)=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}F(\lambda)e^{-\mathrm{i}\lambda x}\mathrm{d}x\tag{9.6.424}$$

Therefore $F(\lambda)$ is the Fourier transform of the desired function such that:

$$F(\lambda)=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}f(x)e^{-\mathrm{i}\lambda x}\mathrm{d}x\tag{9.6.425}$$

Which then gives by injecting the Fourier transform with a change of variable that imposes itself:

$$\begin{aligned}u(x,t)&=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}F(\lambda)e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda=\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\left(\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}f(v)e^{-\mathrm{i}\lambda v}\mathrm{d}v\right)e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda\\&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}\left(\int\limits_{-\infty}^{+\infty}f(v)e^{-\mathrm{i}\lambda v}\mathrm{d}v\right)e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda\end{aligned}\tag{9.6.426}$$

Always keeping in mind that if we put t as being null below, we then fall back well on:

$$u(x,0)=f(x)\tag{9.6.427}$$

Since in the last equality the term $e^{-\lambda^2Dt+\mathrm{i}\lambda x}$ is independent of the variable v, we can put it in the second integral such that:

$$u(x,t)=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}\left(\int\limits_{-\infty}^{+\infty}f(v)e^{-\mathrm{i}\lambda v\mathrm{d}v}\right)e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}\int\limits_{-\infty}^{+\infty}f(v)e^{-\mathrm{i}\lambda v}e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}v\mathrm{d}\lambda\tag{9.6.428}$$

We then recognize a double integral of which we can change the order of integration by applying the Fubini theorem (see section Differential and Integral Calculus page 1521):

$$\begin{aligned}u(x,t)&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}\int\limits_{-\infty}^{+\infty}f(v)e^{-\mathrm{i}\lambda v}e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda\mathrm{d}v=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}f(v)\int\limits_{-\infty}^{+\infty}e^{-\mathrm{i}\lambda v}e^{-\lambda^2Dt+\mathrm{i}\lambda x}\mathrm{d}\lambda\mathrm{d}v\\&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}f(v)\int\limits_{-\infty}^{+\infty}e^{-\mathrm{i}\lambda v}e^{-\lambda^2Dt-\mathrm{i}\lambda(v-x)}\mathrm{d}\lambda\mathrm{d}v\end{aligned}\tag{9.6.429}$$

It then comes in the case that interests us by making a correspondence term by term:

$$\begin{aligned}u(x,t)&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}f(v)\int\limits_{-\infty}^{+\infty}e^{-Dt\lambda^2-\mathrm{i}(v-x)\lambda}\mathrm{d}\lambda\mathrm{d}v=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}f(v)\left(\sqrt{2\pi}\frac{1}{\sqrt{2Dt}}e^{-\frac{(v-x)^2}{4Dt}}\right)\mathrm{d}v\\&=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty}f(v)\frac{\sqrt{\pi}}{\sqrt{Dt}}e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v\end{aligned}\tag{9.6.430}$$

Therefore:

$$\boxed{u(x,t)=\frac{1}{2\sqrt{\pi Dt}}\int\limits_{-\infty}^{+\infty}f(v)e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v}\tag{9.6.431}$$

Thus any function $f(v)$ injected in the above relation will satisfy the initial conditions we have imposed to ourselves:

$$u(x,0)=f(x)f(\pm\infty)\rightarrow 0\tag{9.6.432}$$

Remark

The above solution is sometimes named "Gauss-Weierstrass integral form of the solution" as it is similar to the definition of the "Weierstrass transform" defined by:

$$W[f](x)=\frac{1}{\sqrt{4\pi}}\int\limits_{-\infty}^{+\infty}f(y)e^{-\frac{(x-y)^2}{4}}\mathrm{d}y=\frac{1}{\sqrt{4\pi}}\int\limits_{-\infty}^{+\infty}f(x-y)e^{-\frac{y^2}{4}}\mathrm{d}y\tag{9.6.433}$$

The case with the heat equation having $Dt=1$ is named the "standard Weierstrass transform". By varying Dt (especially by putting $D=1$ and making t varying) we speak of "generalized Weierstrass transform".

For information, many physicists name the following expression visible in the previous boxed relation:

$$K(t,x,v)=\frac{1}{\sqrt{4\pi t}}e^{-\frac{(v-x)^2}{4t}}\tag{9.6.434}$$

The "heat kernel". Thus the final result is in reality only a convolution of $f(v)$ with this "kernel".

In practice this integral is not analytically calculable since it is a convolution with a Gaussian (see section Statistics page 692). This is the reasons for which the heat equation is almost always solved at the initial conditions mentioned above using numerical methods (see section on Numerical Methods page 6753).

But let us solve some simplistic but real cases:

✍**Examples:**

E1. When two ends of a system of size L are maintained at two different temperatures T_1 and T_2, the solution of the heat equation is stationary (independent of time). We then have:

$$\frac{\partial^2 T(x)}{\partial x^2}=0 \tag{9.6.435}$$

The solution to this differential equation is very simple and does not require the use of the previous result (it is elementary integral calculus with known initial conditions):

$$T(x)=T_1+(T_2-T_1)\frac{x}{L} \tag{9.6.436}$$

This is a situation we find in everyday life ...

E2. Let us consider the case where we put in contact two bars of infinite length (since with the Fourier transform it is always necessary that one of the variables range the whole set of real number) and of opposite temperature in sign (on the Celsius scale therefore...) such as:

$$u(x,0)=\begin{cases}+T_0 & \text{if } x>0\\ -T_0 & \text{if } x<0\end{cases} \tag{9.6.437}$$

We then have:

$$\begin{aligned}u(x,t)&=\frac{1}{2\sqrt{xDt}}\int_{-\infty}^{+\infty} f(v)e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v\\&=\frac{1}{2\sqrt{\pi Dt}}\left(\int_{-\infty}^{0} -T_0 e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v+\int_{0}^{+\infty} T_0 e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v\right)\\&=\frac{T_0}{2\sqrt{\pi Dt}}\left(\int_{0}^{+\infty} e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v-\int_{-\infty}^{0} e^{-\frac{(v-x)^2}{4Dt}}\mathrm{d}v\right)\end{aligned} \tag{9.6.438}$$

And let us make the following change of variable:

$$\frac{v-x}{\sqrt{4Dt}}=\frac{v-x}{2\sqrt{Dt}}=\tau \tag{9.6.439}$$

Hence:

$$\mathrm{d}v=-2\sqrt{Dt}\mathrm{d}\tau \tag{9.6.440}$$

Then we have:

$$\begin{aligned}u(x,t)&=\frac{T_0}{2\sqrt{\pi Dt}}\left(\int\limits_{-x/2\sqrt{Dt}}^{+\infty}-2\sqrt{Dt}e^{-\tau^2}\mathrm{d}\tau-\int\limits_{-\infty}^{-x/2\sqrt{Dt}}-2\sqrt{Dt}e^{-\tau^2}\mathrm{d}\tau\right)\\&=\frac{T_0}{\sqrt{\pi}}\left(\int\limits_{-x/2\sqrt{Dt}}^{+\infty}-e^{-\tau^2}\mathrm{d}\tau-\int\limits_{-\infty}^{-x/2\sqrt{2Dt}}-e^{-\tau^2}\mathrm{d}\tau\right)\\&=\frac{T_0}{\sqrt{\pi}}\left(\int\limits_{-x/2\sqrt{Dt}}^{+\infty}-e^{-\tau^2}\mathrm{d}\tau+\int\limits_{-\infty}^{-x/2\sqrt{2Dt}}e^{-\tau^2}\mathrm{d}\tau\right)\\&=\frac{T_0}{\sqrt{\pi}}\left(\int\limits_{-\infty}^{-x/2\sqrt{Dt}}e^{-\tau^2}\mathrm{d}\tau-\int\limits_{-x/2\sqrt{Dt}}^{+\infty}e^{-\tau^2}\mathrm{d}\tau\right)\end{aligned} \tag{9.6.441}$$

Since the integrated function is an even function (see section Functional Analysis page 2212) we have:

$$\int\limits_{-\infty}^{-x/2\sqrt{Dt}}e^{-\tau^2}\mathrm{d}\tau=\int\limits_{x/2\sqrt{Dt}}e^{-\tau^2}\mathrm{d}\tau \tag{9.6.442}$$

Therefore:

$$\begin{aligned}u(x,t)&=\frac{T_0}{\sqrt{\pi}}\left(\int\limits_{-x/2\sqrt{Dt}}^{+\infty}e^{-\tau^2}\mathrm{d}\tau-\int\limits_{-x/2\sqrt{Dt}}^{+\infty}e^{-\tau^2}\mathrm{d}\tau\right)=\frac{T_0}{\sqrt{\pi}}\left(\int\limits_{-x/2\sqrt{Dt}}^{x/2\sqrt{Dt}}e^{-\tau^2}\mathrm{d}\tau\right)\\&=\frac{2T_0}{\sqrt{\pi}}\int\limits_{0}^{x/2\sqrt{Dt}}e^{-\tau^2}\mathrm{d}\tau\end{aligned} \tag{9.6.443}$$

What it is customary to write:

$$u(x,t)=T_0\mathrm{erf}\left(\frac{x}{2\sqrt{Dt}}\right) \tag{9.6.444}$$

Where "erf" is named the "Gauss error function" and can not be analytically computed accurately (we must go through limited series developments). It can however be found in spreadsheets like Microsoft® Excel® under the name `ERF( )`.

9.6.11.1.1 Fick's laws of diffusion

Equations based on Fick's law have been commonly used to model transport processes in foods, neurons, biopolymers, pharmaceuticals, porous soils, population dynamics, nuclear materials, semiconductor doping process, etc. Theory of all voltammetric methods is based on solutions of Fick's equation. A large amount of experimental research in polymer science and food science has shown that a more general approach is required to describe transport of components in materials undergoing glass transition. In the vicinity of glass transition the flow behaviour becomes "non-Fickian".

When two miscible liquids are brought into contact, and diffusion takes place, the macroscopic (or average) concentration evolves following Fick's law. On a mesoscopic scale, that is, between the macroscopic scale described by Fick's law and molecular scale, where molecular random walks take place, fluctuations cannot be neglected. Such situations can be successfully modelled with Landau-Lifshitz fluctuating hydrodynamics. In this theoretical framework, diffusion is due to fluctuations whose dimensions range from the molecular scale to the macroscopic scale.

Integrated circuit fabrication technologies, model processes like CVD (chemical vapor deposition processes), thermal oxidation, wet oxidation, doping, etc. use diffusion equations obtained from Fick's law.

We have just seen the proof of the heat propagation equation proposed by Fourier in 11822 (holocene calendar) obtained from the equation of continuity. We had obtained (it is highly recommended to the reader to refer to it again only to read a second time the remarks relating to the proof):

$$\frac{\partial T(x,t)}{\partial t}-D_T\frac{\partial^2 T(x,t)}{\partial x^2}=0 \tag{9.6.445}$$

Based on the same hypotheses as Fourier, Adolf Fick proposed in 11855 (holocene calendar) that a flow of particles could diffuse through a material according to a similar law, the "Fick's second law" or "Fick's law of diffusion", of the form:

$$\boxed{\frac{\partial \rho(x,t)}{\partial t}-D_p\frac{\partial^2 \rho(x,t)}{\partial x^2}=0} \tag{9.6.446}$$

Where the constant of proportionality D_p is the "diffusion coefficient of matter" and ρ the density of particles per unit volume (and not the mass density!).

Remark

In practice, diffusion plays an essential role in the manufacture of ceramics, semiconductors (doping), solar cells and in the solidification of metals (carbon and heat treatment). Because since two heated materials are taken into contact, their atoms diffuse into each other (also a little bit when not heated).

It must be understood that everything diffuses in everything as we have already mention it in our study of Tribology in the section of Classical Mechanics! So think about pesticides on fruits and vegetables, pollution in ground water, PET in drinks, etc.

Therefore, the relation of the heat surfacic flow of that we have used above to obtain the Fourier law and which was:

$$\vec{\Phi}_q = -\kappa \vec{\nabla} T \tag{9.6.447}$$

can then also be written (we will prove it) in the case of the mass in the form of a flow of particles named the "first Fick's law":

$$\boxed{\vec{\Phi}_p = -D \vec{\nabla} \rho} \tag{9.6.448}$$

where D is the transport coefficient of the material (to be determined ...). We find in the literature this last relation frequently in unidimensional form as following:

$$\Phi_p = -D \frac{\partial \rho}{\partial x} \tag{9.6.449}$$

Either in discrete form:

$$\Phi_p = -D \frac{\Delta \rho}{\Delta x} \tag{9.6.450}$$

If the variation of the distance is put in correspondence with a length L travelled by the diffusion, then we have the notation even more simplified:

$$\Phi_p = -D \frac{\Delta \rho}{L} \tag{9.6.451}$$

Below we can see the gradient density between salt water and fresh water (the transition zone known since more than 2000 years is named "halocline"):

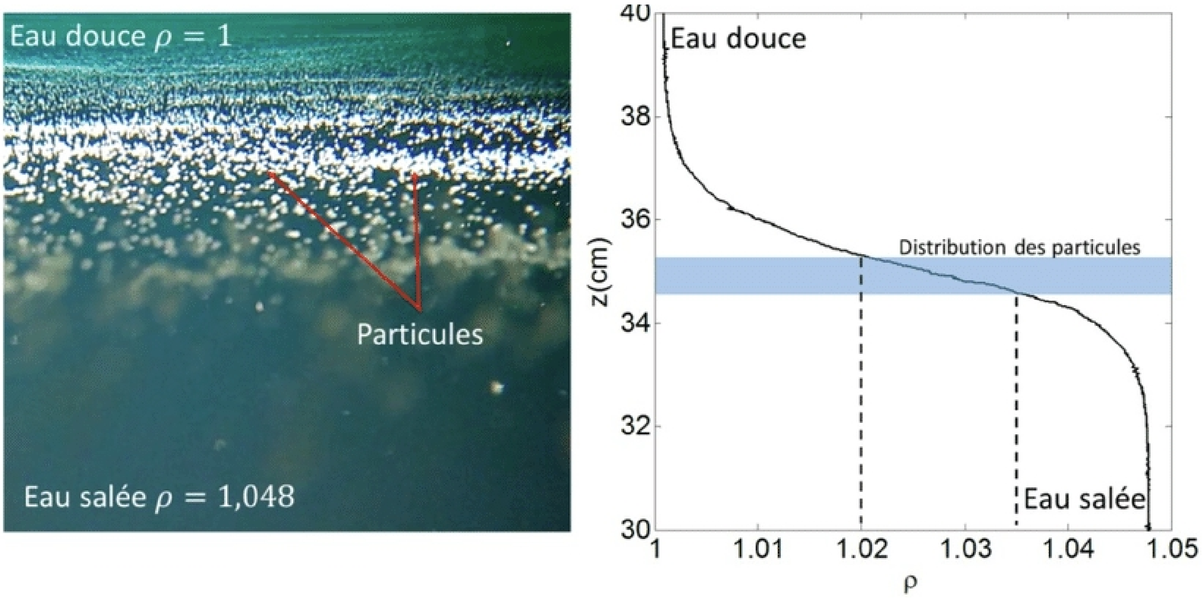

Figure 9.173: **Corresponding density profile for the transition between salt water having a density of $\rho_2 = 1.048$ and fresh water $\rho_1 = 1$ that takes place over approximately $5[\text{cm}]$ (source: [30])**

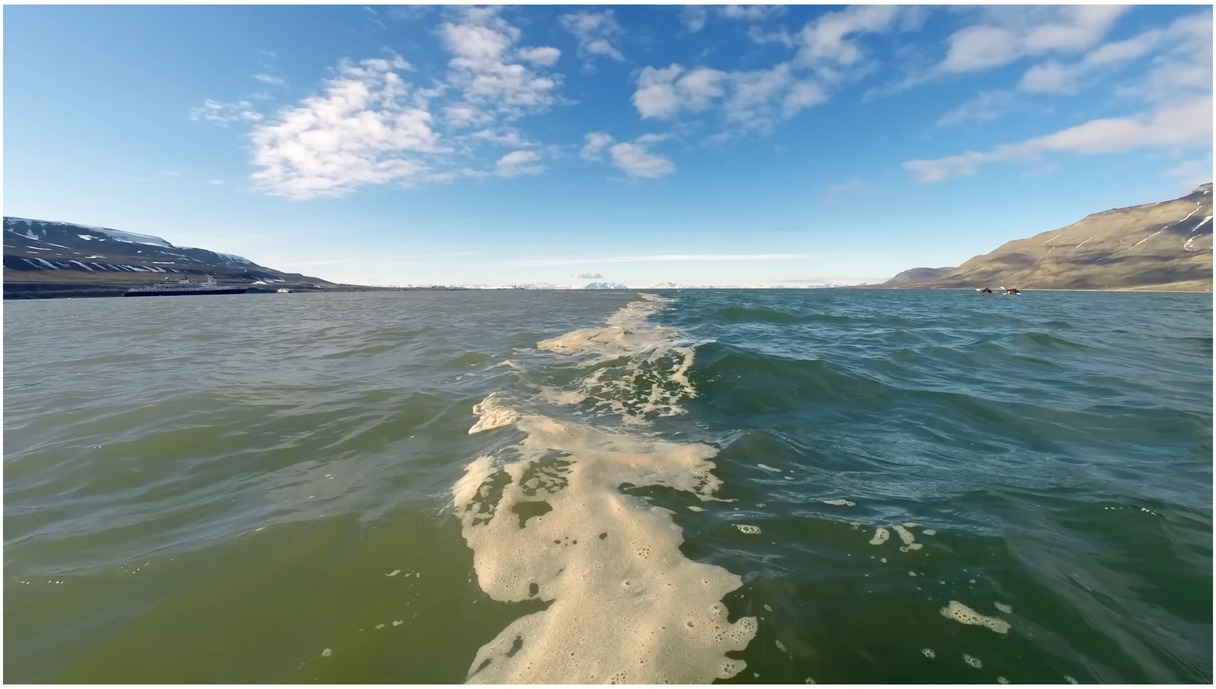
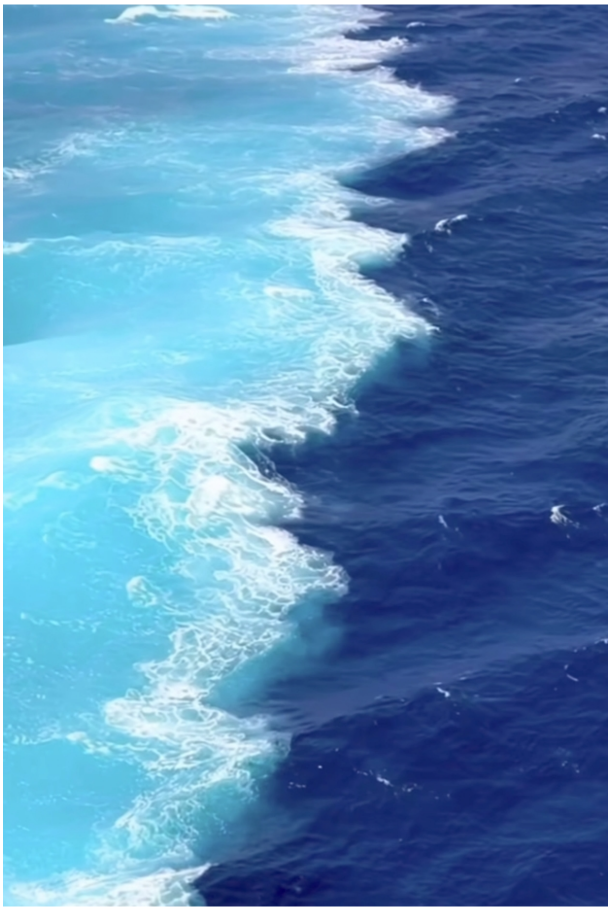
Or with the eyes you can see the gradient diffusion in the photo below (Tasman Sea - that is a salt sea - meets the Pacific Ocean at the very northern tip of New Zealand):



and also on the photo below (Baltic Sea/North Sea in Denmark near Skagen):



Remark

In the field of electrokinetics, the first Fick's law is often denoted by engineers as following:

$$J_{\text{diff}} = -qD\frac{\mathrm{d}\rho}{\mathrm{d}x} \tag{9.6.452}$$

and named the "diffusion current".

To fall back on the famous relation known by small classes of chemistry it is necessary to know that the chemist is accustomed to write the density by the letter C to indicate that it is a **C**oncentration. Therefore, we have:

$$\Phi_p = -D\frac{\Delta C}{L} \tag{9.6.453}$$

But this is not the only change of notation made by chemists. Indeed, it must be remembered that the surfacic flow of particles (mass) is defined by the quantity of mass passing through a constant surface per unit time. We then have:

$$\frac{\dfrac{\Delta m}{\Delta t}}{S} = -D\frac{\Delta C}{L} \tag{9.6.454}$$

Since the origin of time is often taken as zero and the initial mass is zero then we get finally after a small rearrangement the classical relation known by chemists and biologists (to a given sign since it is only a matter of convention) :

$$\boxed{m = -\frac{DS\Delta Ct}{L}} \tag{9.6.455}$$

✍**Example:**

Plants absorb water for photosynthesis. We know from experimental measurements that the diffusion coefficient of water in the air is $D \cong 2.4\cdot 10^{-5}\;[\text{m}^2\cdot\text{s}^{-1}]$. The pores of absorption of plants have a section of the order of $S = 8.0\cdot 10^{-11}\;[\text{m}^2]$. The diffusion distance is of the order of $L \cong 2.5\cdot 10^{-5}\;[\text{m}]$. The water vapour density inside the plant is of the order of $C_2 \cong 0.022\;[\text{kg}\cdot\text{m}^{-3}]$ and outside the plan of $C_1 \cong 0.011\;[\text{kg}\cdot\text{m}^{-3}]$.

Consequently, the mass of water absorbed in one hour is approximately:

$$m = \frac{DS\Delta Ct}{L} \cong \frac{2.4\cdot 10^{-5}\cdot 8\cdot 10^{-11}\cdot(0.022-0.011)\cdot 3600}{2.5\cdot 10^{-5}} \cong 3\cdot 10^{-9}\;[\text{kg}] \tag{9.6.456}$$

This result must be multiplied by the millions of pores that a plant has.

Remark

In the facts, Fick proved at first the first law and proceeding in exactly the same way to the heat equation he obtained the second law that bears his name (that is to say in the opposite order presented above).

We can also estimate the flow of thermal energy transported by these same particles along the x-axis. Indeed, in each slice of fluid, n particles carry each an energy E corresponding to a given amount of heat Q (according to Joule's law). We therefore have a surfacic flux of energy Φ_q whose first component is given by the same type of balance as the previous developments:

$$\Phi_q \cong -\frac{1}{3}\frac{\partial(nQ)}{\partial x}\lambda_x\bar{v} = -\frac{1}{3}\lambda_x\bar{v}\frac{\partial(nQ)}{\partial T}\frac{\partial T}{\partial x} \tag{9.6.457}$$

We find in it immediately the definition of the calorific capacity (if we divide by mass we would have the massic calorific capacity according to what we saw earlier above). Thus, in the one-dimensional case:

$$\boxed{\kappa = \frac{1}{3}\lambda_x\bar{v}C = CD} \tag{9.6.458}$$

There is therefore a simple ratio of proportionality between κ and C.

Fourier's law	**Fick's law**	**Ohm's law**
Thermodynamics	Thermodynamics	Electrokinetics
$\vec{j}_q = -\kappa\vec{\nabla}T$	$\vec{j} = -D\vec{\nabla}\rho$	$\vec{j} = \sigma\vec{E} = -\sigma\vec{\nabla}U$
Thermic current density	Particle current density	Electric current density
T: Temperature	ρ: concentration	U: electric potential
κ: Thermic conductivity	D: coefficient of diffusion	σ: electric conductivity
Thermic flux: $\Phi_q = \iint_S \vec{j}_q \circ \mathrm{d}\vec{S}$	Particle flux: $\Phi_p = \iint_S \vec{j}_p \circ \mathrm{d}\vec{S}$	Electric flux: $I = \iint_S \vec{j} \circ \mathrm{d}\vec{S}$

Table 9.32: **Similarities of different diffusion laws in physics**

Here are some self-diffusion coefficient D_A of some gases at $T = 273$ [K] and $P = 0.1$ [MPa]:

Gas	D_A [cm$^2\cdot$s^{-1}]	Gas	D$_A$ [cm$^2\cdot$s^{-1}]	Gas	D_A [cm$^2\cdot$s^{-1}]
H_2	1.604	O_2	0.192	H_2O	0.276
He	1.386	N_2	0.155	CH_4	0.188
Ar	0.157	CO_2	0.106	NH_3	0.192

And some interdiffusion coeffients D_{AB}:

Diffusing gas A	Medium B	Pressure mmH$_2$O	Temperature [K]	D_{AB} [cm$^2\cdot$s^{-1}]
H_2	He	760	298	1.64
Ar	He	751	288	0.703
N_2	CO_2	760	288	0.158
H_2O	air	760	273	0.219
H_2	N_2	760	288	0.743
H_2O	CO_2	760	273	0.146

And some diffusion coefficients of gases in liquids:

Gas	Liquid	Temperature [K]	D (10^{-5}) $[\text{cm}\cdot\text{s}^{-1}]$
Air	water	293	2.5
CO_2	water	298	1.92
H_2	water	298	4.50
NH_3	water	285	1.64
CO_2	ethanol	298	3.42
CO_2	heptane	298	6.03

9.6.12 Thermal radiation

Thermal radiation is electromagnetic radiation generated by the thermal motion of charged particles in matter. All matter with a temperature greater than absolute zero emits thermal radiation. When the temperature of a body is greater than absolute zero, inter-atomic collisions cause the kinetic energy of the atoms or molecules to change. This results in charge-acceleration and/or dipole oscillation which produces electromagnetic radiation, and the wide spectrum of radiation reflects the wide spectrum of energies and accelerations that occur even at a single temperature.

Examples of thermal radiation include the visible light and infra-red light emitted by an incandescent light bulb, the infra-red radiation emitted by animals is detectable with an infra-red camera, and the cosmic microwave background radiation. Thermal radiation is different from thermal convection and thermal conduction person near a raging bonfire feels radiant heating from the fire, even if the surrounding air is very cold.

Sunlight is part of thermal radiation generated by the hot plasma of the Sun. The Earth also emits thermal radiation, but at a much lower intensity and different spectral distribution (infra-red rather than visible) because it is cooler. The Earth's absorption of solar radiation, followed by its outgoing thermal radiation are the two most important processes that determine the temperature and climate of the Earth.

If a radiation-emitting object meets the physical characteristics of a black-body in thermodynamic equilibrium, the radiation is named "black-body radiation". Planck's law describes the spectrum of black-body radiation, which depends only on the object's temperature. Wien's displacement law determines the most likely frequency of the emitted radiation, and the Stefan–Boltzmann law gives the radiant intensity.

Thermal radiation is one of the fundamental mechanisms of heat transfer.

9.6.12.1 Black Body radiation

Black-body radiation is the type of electromagnetic radiation within or surrounding a body in thermodynamic equilibrium with its environment, or emitted by a black-body (an opaque and non-reflective body), assumed for the sake of calculations and theory to be held at constant, uniform temperature. The radiation has a specific spectrum and intensity that depends only on the temperature of the body.

The thermal radiation spontaneously emitted by many ordinary objects can be approximated as black-body radiation. A perfectly insulated enclosure that is in thermal equilibrium internally contains black-body radiation and will emit it through a hole made in its wall, provided the hole is small enough to have negligible effect upon the equilibrium.

A black-body at room temperature appears black, as most of the energy it radiates is infra-red and cannot be perceived by the human eye. Because the human eye cannot perceive color at very low light intensities, a black-body, viewed in the dark at the lowest just faintly visible temperature, subjectively appears grey (but only because the human eye is sensitive only to black and white at very low intensities - in reality, the frequency of the light in the visible range would still be red, although the intensity would be too low to discern as red), even though its objective physical spectrum peaks in the infra-red range. When it becomes a little hotter, it appears dull red. As its temperature increases further it eventually becomes blue-white.

Although planets and stars are neither in thermal equilibrium with their surroundings nor perfect black bodies, black-body radiation is used as a first approximation for the energy they emit.[6] Black holes are near-perfect black bodies, in the sense that they absorb all the radiation that falls on them. It has been proposed that they emit black-body radiation (named "Hawking radiation"), with a temperature that depends on the mass of the Black Hole.

The study of the black-body is the basis of the famous theory of Wave Quantum Physics (see section of the same name page 4616), one of the pillars of actual modern physics. Indeed, some experimental results could not be explained without the introduction of the famous Planck constant, the use of quantification of energy (quanta) and the acceptance of the atomic model and Boltzmann statistical theory (implicitly the second principle of thermodynamics of which Max Planck was a specialist).

Before starting we will make an exceptionally (for this textbook) an historical hook which that we suppose to be very useful to understand why the study of thermal radiation is so important in physics.

The fact that all heated objects emit a light of the same color at the same temperature is a curiosity that had been known for centuries in some fields, long before Gustav Krichhoff began his scientific and theoretical investigations on the nature of this strange correlation. To simplify his analysis, he elaborated the concept of a perfectly absorbing and perfectly emissive object. Thus, as a perfect transmitter, it would be anything but black if its temperature were high enough so that it could radiate in wavelengths of the visible part of the spectrum. Therefore, with respect to experience feedback, the radiation of this object would have an intensity and a spectral extent independent of the type of material of which it is composed. The objective was then to measure the spectral distribution of the radiated energy for each wave length and for each temperature plateau and to derive an equation and therefore dependent of two variables (wavelength and temperature) to reproduce this distribution and therefore this for any material placed under the conditions of a perfectly emessive and receptive body.

Definition (#9.6.465): A "black-body" (or "integral receiver") is defined as a body having an "energy absorption coefficient α" (see section Optical Geometry page 4351) and an "emissivity coefficient ε" equal to the unity.

Definition (#9.6.466): The emissive power of an arbitrary opaque body of fixed size and shape at a definite temperature can be described by a dimensionless ratio, named "emissivity", the ratio of the emissive power of the body to the emissive power of a black-body of the same size and shape at the same fixed temperature[28].

The first principle of thermodynamics establishes an equivalence between work and heat as modes of energy transfer between a system and its environment (and in fact the balance in terms of internal energy). We are interested here in the heat, which we can be define as "the energy one body communicates to another because of their temperature difference".

Heat is, for recall, communicated from one place to another in three different ways, as we have already mentioned earlier above:

1. By conduction: it is a transfer of heat in a set of material points in contact which takes place without macroscopic movements, under the influence of a temperature gradient. Conduction is therefore the result of molecular collisions. We observe it mainly in solids: in metals, it involves the free electrons which make them good conductors of heat. On the other hand, in insulators, conduction is badly done. Hence the strong correspondence between the thermal and electrical properties of solids.
2. By convection: convection involves the transport of heat by a part of a fluid that mixes with another fluid or material. It has its origin in a macroscopic transport of matter and therefore does not concern solids most of time.
3. By radiation: conduction and convection assume the presence of matter. Radiation, on the other hand, allows a transfer of energy that can be made through the vacuum. This is electromagnetic radiation. It should be noted that radiation is not a mode of heat transfer but energy, which can be transformed into heat in contact with a body.

The thermal radiation emitted by a body at a given temperature results from a conversion of the internal energy of the body into radiation (excited quantum state level back to ground level). Conversely, absorption is the transformation of the incident energy into internal energy.

When a surface is subjected to absorbed radiation, we perform the energy balance according to the Kirchhoff law seen in our study of photometry (see section Optical Geometry page 4351):

$$\alpha+\rho+\tau=1 \tag{9.6.459}$$

where let us recall that α is the fraction of the absorbed radiation, ρ is the reflected part (scattered) and τ the transmitted part (which crosses the surface). This balance schema results from the principle of energy conservation.

---

[28] With this definition, Kirchhoff's law states that for an arbitrary body emitting and absorbing thermal radiation in thermodynamic equilibrium, the emissivity is equal to the absorptivity.

We will now examine the mechanisms of absorption and emission and establish a link between heat and radiant energy before we to focus directly to the black-body:

9.6.12.1.1 Stefan–Boltzmann law

In our study of photometry, we defined the concept of emittance (energy irradiated by a non-punctual body per unit area) for the entire spectrum.

What we had omitted to specify, however, is that in order for a body to radiate (apart from the fact that it can itself be illuminated by another body) it must be heated (that we provide an excitation energy to the constituents of the body in question - that is to say to the electrons).

So we should be able to establish a relation between the temperature of a body and its emittance.

In 11879 (holocene calendar), the physicist Jožef Stefan was able to establish experimentally that the total emittance of the black-body (or "energetic excitance" also named "radiant exitance" of the black-body) at a temperature T increased in proportion to the fourth power of the temperature such that:

$$\boxed{M(T)=\sigma T^4} \tag{9.6.460}$$

Where $M(T)$ is the integration on all wavelengths (or frequencies ... whatever) of $M(\lambda,T)$:

$$M(T)=\int\limits_0^{+\infty} M(\lambda,T)\mathrm{d}\lambda \tag{9.6.461}$$

with $M(\lambda,T)$ given by the Planck law which we prove further below.

Let us also recall that (this will be shown during our proof of Planck's law):

$$\sigma\cong 5.670374419\cdot 10^{-8}\;[\mathrm{W}\cdot\mathrm{m}^{-2}\cdot\mathrm{K}^{-4}] \tag{9.6.462}$$

is the "Stefan constant" (not to be confused with Stefan-Boltzmann's constant !!!).

In 11884 (holocene calendar), Ludwig Boltzmann indirectly proved Stefan's law on the basis of the study of the black-body in thermal equilibrium (where we consider that the border of the black-body wall define the terminations of electromagnetic waves) from the theory of electromagnetism and using a powerful thermodynamic reasoning.

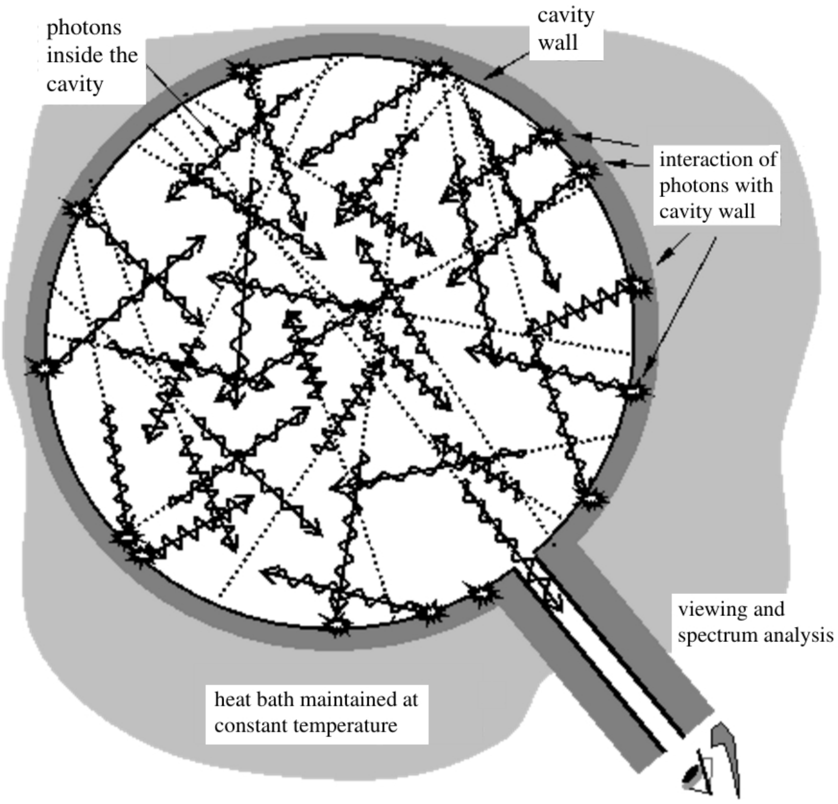
Proof 9.10.5. In a first step, Boltzmann determined the radiation pressure in such an enclosure (or in such a body).

Here are the developments that led him to determine the radiation pressure $P(T)$ at the thermodynamic equilibrium temperature T for the corresponding internal energy density $\rho(T)$:

Let us recall the expression of the "Einstein relation" that we have proved during our study of Special Relativity:

$$p=\frac{h\nu}{c} \tag{9.6.463}$$

Let us consider now a chamber of volume V whose walls are reflective for the photons (case of the black-body):



photons
inside the
cavity
cavity
wall
interaction of
photons with
cavity wall
viewing and
spectrum analysis
heat bath maintained at
constant temperature

Figure 9.174: **Conceptual black-body**

We study the variation of the momentum before and after the collision on an infinitely small surface $\mathrm{d}s$ (which makes it possible to consider the trajectories before and after the impact as rectilinear and symmetrical with respect to the oriented axis $\mathrm{O}x$ perpendicular to the surface of the black-body coinciding with the surface $\mathrm{d}s$).

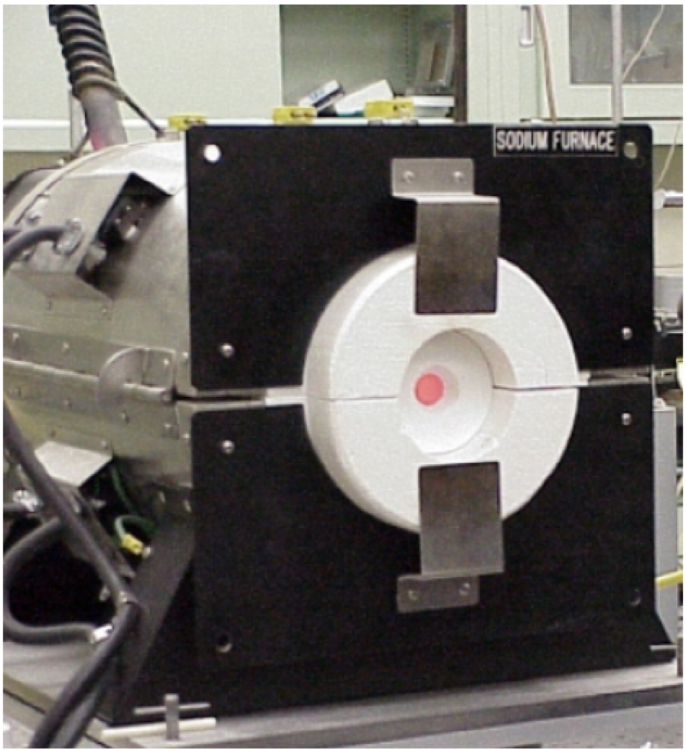


Figure 9.175: **Black-body laboratory radiator**

Thus, we have before collision for the linear momentum:

$$\vec{p}=p_x\vec{u}_x+p_y\vec{u}_y \tag{9.6.464}$$

and after collision:

$$\vec{p}\,'=-p'_x\vec{u}_x+p'_y\vec{u}_y \tag{9.6.465}$$

If the collision is elastic (which is comforting relative to the photon ...):

$$|p'_x|=|p_x| \qquad |p'_y|=|p_y| \tag{9.6.466}$$

Then we have:

$$\vec{p}\,'=-p_x\vec{u}_x+p_y\vec{u}_y \tag{9.6.467}$$

The variation of the momentum is then:

$$\mathrm{d}\vec{p}=\vec{p}\,'-\vec{p}=(-p_x\vec{u}_x+p_y\vec{u}_y)-(p_x\vec{u}_y+p_y\vec{u}_y)=-2p_x\vec{u}_x \tag{9.6.468}$$

As:

$$p_x=p\cos(\alpha) \tag{9.6.469}$$

then we have:

$$\mathrm{d}\vec{p}=-2p\vec{u}_x\cos(\alpha) \tag{9.6.470}$$

By considering only the norm of the expression and that it is a single photon:

$$\mathrm{d}p=2\frac{h\nu}{c}\cos(\alpha) \tag{9.6.471}$$

Remark

We assume that after its rebound, the photon conserves its frequency which leads us to suppose that the black-body has stationary waves at thermodynamic equilibrium (see section Wave Mechanics page 3520).

Until now, we have reasoned on a single photon, but the enclosure actually contains a gas of photons. The internal volume energy u of the radiation contains a volumetric density n of photons of identical frequency ν. Consequently, the quantity n of photons per unit volume in the enclosure is:

$$n=\frac{u}{h\nu}\,[\mathrm{m}^{-3}] \tag{9.6.472}$$

Remark

We specify the units, because we noticed that the following development sometimes presented some problems of understanding to some readers if the units were not given explicitly.

We consider that during a time interval $\mathrm{d}t$ the number of photons potentially striking the surface $\mathrm{d}s$ at an angle of incidence α is contained in a cylinder of generator $c\mathrm{d}t$ whose axis is necessarily inclined by an angle α and having as base area $\mathrm{d}s$. The volume of this cylinder is then by the projection of the base surface: The number of photons $\mathrm{d}n_c$ that potentially strike the wall $\mathrm{d}s$ per unit time is:

$$\mathrm{d}n_c=n\mathrm{d}V=\frac{u}{h\nu}\mathrm{d}V=\frac{uc}{h\nu}\cos(\alpha)\mathrm{d}s\mathrm{d}t \tag{9.6.473}$$

In this last expression, we assumed that all the photons of $\mathrm{d}V$ had a linear momentum in the direction subtended by α. In fact, the photons actually arriving at $\mathrm{d}s$ are contained in a solid angle $\mathrm{d}\Omega$ between two cones of half-angle at the apex of α and $\alpha+\mathrm{d}\alpha$ (for reasons of the geometry of the black-body's experiment which was, except error, spherical and by the way this spherical symmetry facilitates the calculations...).

The relation between $\mathrm{d}\Omega$ and α is as we have proved in the section of Trigonometry:

$$\mathrm{d}\Omega=\mathrm{d}(2\pi(1-\cos(\alpha))=2\pi\sin(\alpha)\mathrm{d}\alpha \tag{9.6.474}$$

Knowing that in the whole volume (for recall), the solid angle is:

$$\Omega=\frac{4\pi r^2}{r^2} \tag{9.6.475}$$

the number $\mathrm{d}n$ included in the elementary solid angle $\mathrm{d}\Omega$ which reaches the surface $\mathrm{d}s$ at an angle of incidence between α and $\mathrm{d}\alpha$ is then:

$$\mathrm{d}n=\frac{\mathrm{d}\Omega}{\Omega}\mathrm{d}n_c=\frac{2\pi\sin(\alpha)\mathrm{d}\alpha}{4\pi}\frac{uc\cos(\alpha)}{h\nu}\mathrm{d}s\mathrm{d}t=\frac{uc\sin(\alpha)\cos(\alpha)\mathrm{d}\alpha\mathrm{d}s\mathrm{d}t}{2h\nu} \tag{9.6.476}$$

Using now the definition of the pressure P:

$$P=\frac{\mathrm{d}F}{\mathrm{d}s}=\frac{F\mathrm{d}n}{\mathrm{d}s}=\frac{\left(\dfrac{\mathrm{d}p}{\mathrm{d}t}\right)\mathrm{d}n}{\mathrm{d}s} \tag{9.6.477}$$

by substituting what is covenant:

$$P=\frac{\frac{\mathrm{d}p}{\mathrm{d}t}\mathrm{d}n}{\mathrm{d}s}=\frac{\frac{2\frac{h\nu}{c}\cos(\alpha)}{\mathrm{d}t}\frac{uc\sin(\alpha)\cos(\alpha)}{2h\nu}}{\mathrm{d}s} \tag{9.6.478}$$

Which gives after simplification:

$$P=u\sin(\alpha)\cos^2(\alpha)\mathrm{d}\alpha=u\cos^2(\alpha)\mathrm{d}(-\cos(\alpha) \tag{9.6.479}$$

The total pressure of radiation being given in this case by:

$$P=nh\nu\int\limits_0^{\pi/2}\cos^2(\alpha)\mathrm{d}(-\cos(\alpha))=-nh\nu\frac{\cos^2(\alpha)}{3}\bigg|_0^{\pi/2}=\frac{nh\nu}{3} \tag{9.6.480}$$

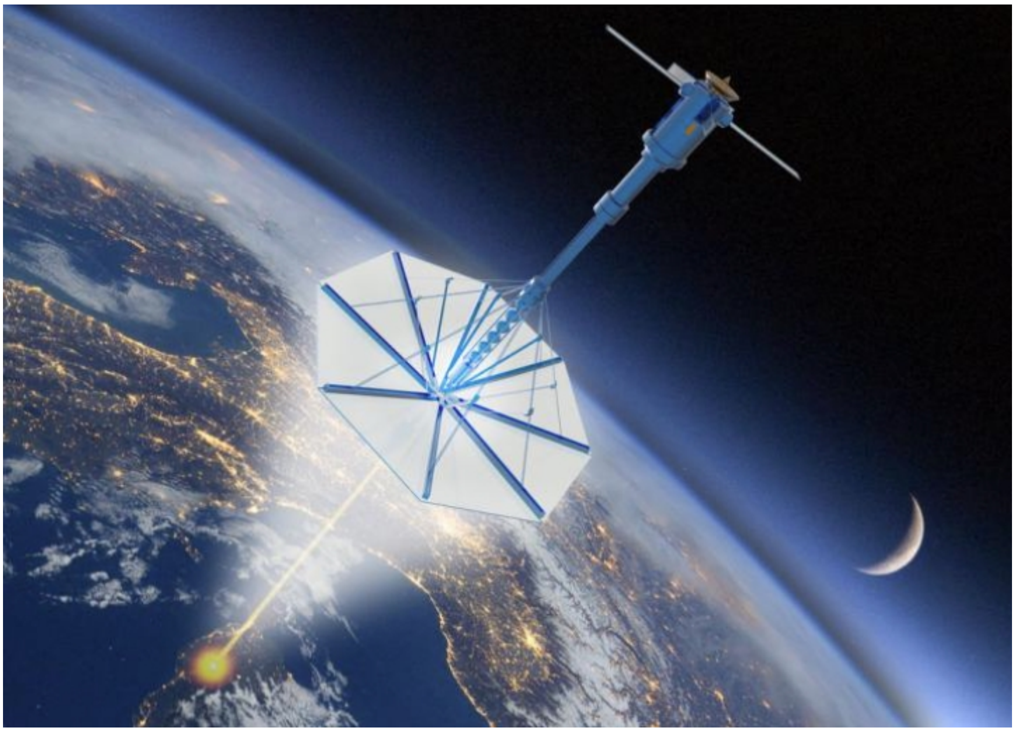
Which is equivalent to write (at equilibrium temperature for a given temperature):

$$\boxed{P(T)=\frac{\rho(T)}{3}} \tag{9.6.481}$$

Relation that is very important and will be useful to us in the section Cosmology during our study of some Friedman Universe models . This relation is also important for rocket science using propulsion by radiation!

As we have seen it in the table of most common pressure level at the beginning of this chapter, remember that the radiation pressure at the surface of the Sun (actually a G2V-type star, aka yellow dwarf) is 0.2 [Pa] and 0.05 [μPa] at Earth level. It quite obviously decrease as the inverse of the square of distance from the Sun!

LASER powered space objects with a LASER based on Earth is very unlikely to happen as the power of a LASER able to counterbalance Earth or Sun gravity is far beyond the technology available in the 121st century (holocene calendar) and even if it was, such a LASER beam would have too many side effects on the local atmosphere (ionization) to be tolerated by humans and politics. We may solve the problem of the ionized atmosphere by boarding the LASER on the space vehicle but there will be therefore the problem of the source power of the LASER that is still too huge to be reliable on a long period of time as required for interstellar travels (at least in the 121st century and very likely for the few next centuries too excepted if we found a new type of extra light source of energy...).



The total energy is the energy density multiplied by the considered volume:

$$E=\rho(T)V \tag{9.6.482}$$

Let us suppose that the volume could vary. The work done by the radiation pressure during a dilatation $\mathrm{d}V$ is obviously given by (dimensional analysis):

$$\mathrm{d}W=-P(T)\mathrm{d}V=-\frac{\rho(T)}{3}\mathrm{d}V \tag{9.6.483}$$

The variation of internal energy of the system following the first principle of thermodynamics is:

$$\mathrm{d}E=\delta Q+\delta W \tag{9.6.484}$$

But as $E=\rho(T)V$, we have:

$$\mathrm{d}E=\mathrm{d}\rho(T)V+\rho(T)\mathrm{d}V=\mathrm{d}\rho(T)V\frac{\mathrm{d}T}{\mathrm{d}T}+\rho(T)\mathrm{d}V \tag{9.6.485}$$

Hence:

$$\delta Q=\mathrm{d}E-\delta w=\rho(T)\mathrm{d}V+\frac{\mathrm{d}\rho(T)V\mathrm{d}T}{\mathrm{d}T}-\left(-\frac{\rho(T)}{3}\mathrm{d}V\right)=\frac{4}{3}\rho(T)\mathrm{d}V+\frac{\mathrm{d}\rho(T)V\mathrm{d}T}{\mathrm{d}T} \tag{9.6.486}$$

and following the second principle of thermodynamics (do not confuse here the notation of the entropy S with that of a surface S...) we have for an ideal reversible system:

$$\mathrm{d}S=\frac{\delta Q}{T} \tag{9.6.487}$$

We have then:

$$\mathrm{d}S=\frac{4}{3}\frac{\rho(T)\mathrm{d}V}{T}+\frac{\mathrm{d}\rho(T)V\mathrm{d}T}{T\mathrm{d}T} \tag{9.6.488}$$

Rearranged this can be written:

$$\mathrm{d}S=\frac{4}{3}\frac{\rho(T)}{T}\mathrm{d}V+\frac{\mathrm{d}\rho(T)V}{T\mathrm{d}T}\mathrm{d}T=\frac{\partial S}{\partial V}\mathrm{d}V+\frac{\partial S}{\partial T}\mathrm{d}T \tag{9.6.489}$$

As $\mathrm{d}S$ is a total exact differential, we have proved in the section of Differential and Integral Calculus that tan S satisfy the Schwarz' theorem:

$$\frac{\partial^2 S}{\partial T\partial V}=\frac{\partial^2 S}{\partial V\partial T} \tag{9.6.490}$$

We have in this case:

$$\frac{\mathrm{d}}{\mathrm{d}T}\left(\frac{4}{3}\frac{\rho(T)}{T}\right)=\frac{\mathrm{d}}{\mathrm{d}V}\left[\frac{\mathrm{d}\rho(T)V}{T\mathrm{d}T}\right]=\frac{\mathrm{d}\rho(T)}{T\mathrm{d}T} \tag{9.6.491}$$

Which bring us to write:

$$\frac{\mathrm{d}\rho(T)}{T\mathrm{d}T}=\frac{4}{3}\frac{\mathrm{d}}{\mathrm{d}T}\left(\frac{\rho(T)}{T}\right) \tag{9.6.492}$$

By calculating the derivative of the right member:

$$\frac{\mathrm{d}\rho(T)}{T\mathrm{d}T}=\frac{4}{3}\frac{\frac{\rho(T)}{\mathrm{d}T}T-\rho(T)\frac{\mathrm{d}T}{\mathrm{d}T}}{T^2} \tag{9.6.493}$$

By simplifying:

$$\frac{\mathrm{d}\rho(T)}{\mathrm{d}T}=\frac{4}{3}\frac{\rho(T)}{\mathrm{d}T}-\frac{4}{3}\frac{\rho(T)}{T} \tag{9.6.494}$$

after rearranging:

$$\frac{\mathrm{d}\rho(T)}{\mathrm{d}T}\left(1-\frac{4}{3}\right)=-\frac{4}{3}\frac{\rho(T)}{T} \tag{9.6.495}$$

Thus:

$$-\frac{1}{3}\frac{\mathrm{d}\rho(T)}{\mathrm{d}T}=-\frac{4}{3}\frac{\rho(T)}{T} \tag{9.6.496}$$

which become the equation:

$$\frac{\mathrm{d}\rho(T)}{\rho(T)}=4\frac{\mathrm{d}T}{T} \tag{9.6.497}$$

Which gives after a trivial integration:

$$\ln(\rho(T))=4\ln(T)+c^{te} \tag{9.6.498}$$

Finally:

$$\rho(T)=c^{te}T^4 \tag{9.6.499}$$

which is commonly written:

$$\boxed{\rho(T)=\sigma_{\text{S.B.}}T^4} \tag{9.6.500}$$

with:

$$\sigma_{\text{S.B.}}=7.56\cdot 10^{-16}\,[\text{J}\cdot\text{m}^{-3}\cdot\text{K}^{-4}] \tag{9.6.501}$$

being the Stefan-Boltzmann constant with the value and the units as they were given at the time of Stefan and Boltzmann and initially experimentally (very far from the present known value known with different units than those in use today)! We will prove however further below the theoretical value with the common units used in the 120th century (holocene calendar).

We see above the correspondence which exists between the relation which we had posed at the beginning and that which we have just obtained:

$$\rho(T)=\sigma_{\text{S.B.}}T^4 \qquad M(T)=\sigma T^4 \tag{9.6.502}$$

Since we have not yet proved Planck's law at this point, we can make a daring reasoning but which we will later justify with a proof as support.

Remark

The last two relations gives us a fundamental information that all bodies that are not at zero kelvin (absolute zero) radiate!

$M(T)$ and $\rho(T)$ are differentiated at the level of the units by the dimensions of a velocity. Now, intuitively and roughly (...), the speed which can immediately appear to us as trivial in this case of study is the speed of light c. Thus, we notice that:

$$\frac{\sigma}{\sigma_{\text{S.B.}}}=\frac{c}{4} \tag{9.6.503}$$

Remark

The product $\frac{4}{c}\sigma$ is sometimes known as the "radiation constant" or "radiation density constant".

Which gives us the Stefan–Boltzmann law expressed as a formula for radiation energy density :

$$\boxed{M(T)=\frac{c}{4}\rho(T)=\frac{c}{4}\sigma_{\text{S.B.}}T^4} \tag{9.6.504}$$

Curious isn't it...? But we will prove it later because our philosophy in this textbook is to never (or as little as possible) leave room for intuition.

■ Q.E.D.

Remark

When we will study Planck's law, the $\rho(T)$ will be denoted $R(T)$ to not to confuse then energy density with the radiance (because the notation can unfortunately be confusing).

Let us consider now an isolated chamber or cavity (like a furnace) in thermal equilibrium at a certain temperature T. This cavity will surely be filled with electromagnetic radiations of different wavelengths. Let us suppose that there exists a distribution function $M(T)$ which depends only on the temperature.

Logically, the total quantity of electromagnetic energy at all wavelengths absorbed by the walls of the cavity must be equal to that emitted by the walls otherwise the body forming the cavity would see its temperature change. Gustav Robert Kirchhoff reasoned that if the body forming the cavity is made of different materials (thus behaving in different ways with temperature), then the equilibrium between emitted radiation and absorbed radiation must apply for each wavelength (or domain of wave length).

We thus see that $M(T)$ is a universal function, the same for all the cavities, regardless of their composition, their geometry or the color of their walls. Kirchhoff did not give this function, but he pointed out that a perfectly absorbing body, that is to say a body for which $\alpha=1$ will appear, how to say... : black.

It comes then that the radiation stored in equilibrium in an isolated cavity in thermodynamic equilibrium is in all aspects the same as that emitted by a perfectly black-body at the same temperature.

Obviously, if the cavity is closed, we can not measure the current of energy that escapes. But let us create a very small hole in this cavity (small enough not to disturb the equilibrium of the electromagnetic radiation inside), then the electromagnetic energy escaping from this small hole is the same as that emitted by a perfectly body black.

However, no object is actually a black-body. Coal black has an absorption coefficient very close to 1 but only for certain frequencies (including, of course, the visible frequencies). Its absorption coefficient is much smaller in the far infra-red. However most objects approach the behaviour of a black-body in certain frequency ranges. The human body, for example, is almost a black-body in the infra-red (hence the military night glasses ...). To treat the various bodies, named "gray body", we introduce a factor named "total emissivity" that connects the emittance emitted by the body to that emitted by a perfect black-body for which $\varepsilon=1$ (for steel the emittance is approximately equal to 0.06). Then we have:

$$\boxed{M(T)=\varepsilon\sigma T^4} \tag{9.6.505}$$

Practitioners of thermodynamics often prefer the following writing (which is actually more coherent in the context of pure thermodynamics):

$$Q=\varepsilon\sigma S T^4 \tag{9.6.506}$$

It is a very sympathetic relation because in all cases by putting $\varepsilon=1$ the curious can know for a given surface what it is the energy (or heat) at the worst (or at best following the point of view ...) emitted by a body of a certain surface at a certain temperature.

Remark

The Stefan-Boltzmann relation gives us the power emitted by a body per unit of surface by expressing it proportionally to the fourth power of the temperature. This exponent gives us the reason why it becomes more and more difficult to increase the temperature of a body by heating it, the latter losing more and more rapidly the energy that we provide for its heating.

In the figure below we have depicted the situation in which the heat bath of the previous figure is produced by an ideal gas of indefinite extent for which there would be no fringe effects:

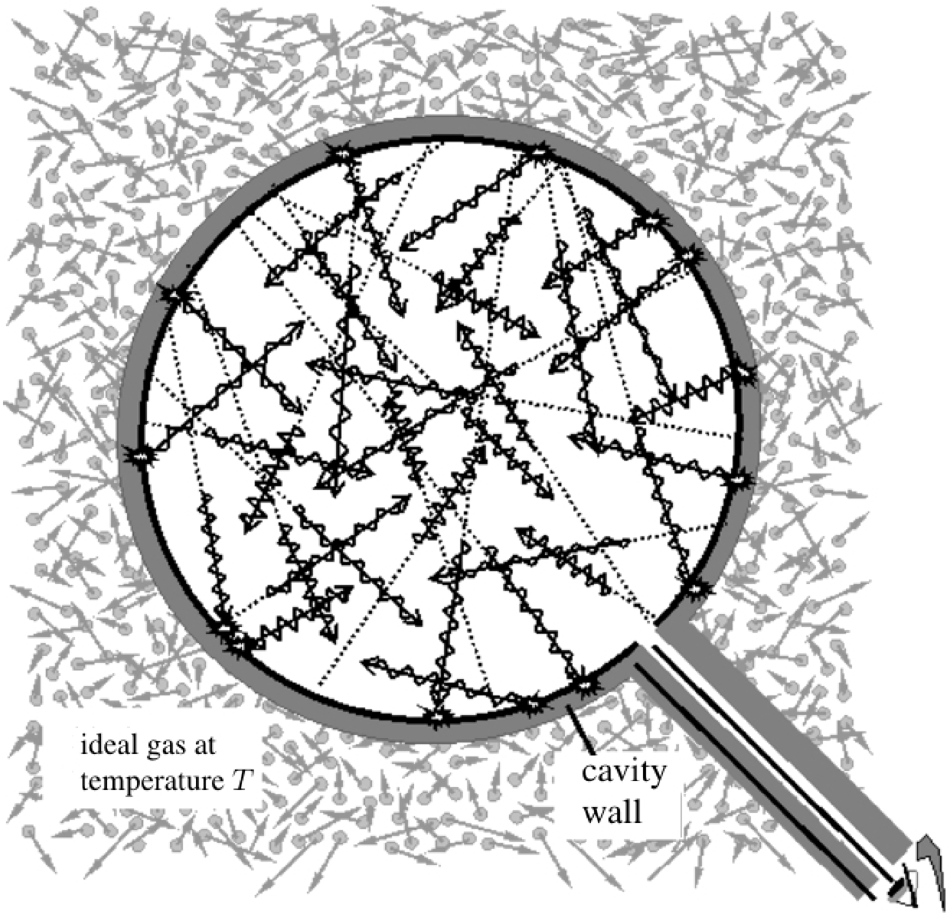


Figure 9.176: **Conceptual black-body with outside gas bath**

The temperature of the gas is maintained at the required value of the cavity wall. In an equilibrium situation characterized by the conservation of energy, total energy will be partitioned equally among all constituents of a gas. This includes not only particulate components of the gas, but also the thermalized photons of electromagnetic energy.

In this figure, as in the prior previous figure, all photons are seen to have originated as emissions or reflections off the wall of the cavity, and are assumed to remain unchanged during transmission unless and until they interact with the cavity wall in a subsequent scattering event. However, for a "bath" comprised of the stationary state ideal gas shown in the figure above, the situation is similar to taking away the cavity wall altogether and allowing the gas to move freely throughout what was formerly the cavity as is now shown in the figure further below.

Photons would then scatter off of particles in the gas rather than the wall of the cavity, but to similar effect. However, in order that it indeed be to similar effect, the gas must be dense enough or its extent great enough that the same density of photons is realized within the conceptual cavity walls as shown.

9.6.12.1.2 Planck's law

To establish Planck's law, we are not going to make the original development of Max Planck even if interesting of the intuitively point of view it was only a succession of tinkering (admitted by Max Planck himself). We will introduce this law with a modern and as simple as possible approach in the point of view of the mathematical formalism as done by Albert Einstein itself!

For this we now consider the black-body as an isolated system at thermal equilibrium, in which the radiation is in the stationary state and reflected totally by the walls. The photons can therefore be considered as particles not interacting with one another in a potential well with rectilinear walls.

Thus, identically to what we have seen in the section of Wave Quantum Physics, the solution of the problem is that of a potential well with rectilinear walls for which we have obtained for wave function:

$$\Psi_x=\Psi_{x,0}\sin(\omega x)=\Psi_{x,0}\sin\left(x\sqrt{\frac{8\pi^2 m}{h^2}(E_{\text{tot}}-E_p)}\right) \tag{9.6.507}$$

function to which the boundary conditions should be applied.

The conditions we imposed during our study of this case in the section of Wave Quantum Physics were too restrictive (this is why they are named "strict boundary conditions"). Indeed, atoms of the wall absorb and emit radiation irrespective of how the radiation incident. But equilibrium imposes at least that boundary conditions are periodic by the very definition of equilibrium. This is why we impose what we name the "periodic boundary conditions":

- For $x=0$ and $x=L_x$, we have: $\Psi(0)=\Psi(L_x)=c^{te}$
- The wave function Ψ must have an integer number of half wavelengths over the length L_x
- In the black-body, $U=0$ therefore $E_p=0$
- If at the ends ($x=0$ and $x=L_x$) we have $\Psi=c^{te}$ the argument of the sine has the same value $n2\pi$ (to a given integer multiplicative factor) in 0 and in L_x.

So we must have:

$$L_x\sqrt{\frac{8\pi^2 m}{h^2}(E_{\text{tot}}-E_p)}=n_x 2\pi \tag{9.6.508}$$

and as $E_p = 0$, after some elementary algebraic simplifications, we get:

$$\frac{8\pi^2 m}{h^2}E_{\text{tot}} = \frac{n_x^2}{L_x^2}4\pi^2 \Rightarrow E_{nx} = \frac{n_x^2}{L_x^2}4\pi^2\frac{h^2}{8\pi^2 m} = \frac{n_x^2}{L_x^2}\frac{h^2}{2m} \tag{9.6.509}$$

Where E_{nx} is the total energy of the quantum level n according to x (see section Wave Quantum Physics page 4616).

The total energy of the particle thus presents a discrete sequence of values, the only ones permitted. The value of L_x is determined using the Bohr or Sommerfeld model, depending on the case.

Since the corresponding wave functions in the well are such that $U = 0 \Leftrightarrow E_p = 0$, we have therefore:

$$\begin{aligned}\Psi_x &= \Psi_{x,0}\sin\left(x\sqrt{\frac{8\pi^2 m}{h^2}E_{\text{tot}}}\right) = \Psi_{x,0}\sin\left(\frac{8\pi^2 m}{h^2}\frac{n_x^2}{L_x^2}\frac{h^2}{2m}\right) = \Psi_{x,0}\sin\left(x\sqrt{\frac{4\pi^2 n_x^2}{L_x^2}}\right)\\ &= \Psi_{x,0}\sin\left(\frac{2\pi n_x}{L_x}x\right) = \Psi_{x,0}\sin(k_x x)\end{aligned} \tag{9.6.510}$$

Thus, the total energy can be written:

$$E_{nx} = \frac{n_x^2}{L_x^2}\frac{2\pi^2\hbar^2}{m} = \frac{\hbar^2}{2m}\frac{4\pi^2 n_x^2}{L_x^2} = \frac{\hbar^2}{2m}\left(\frac{2\pi n_x}{L_x}\right)^2 = \frac{\hbar^2}{2m}k_x^2 \tag{9.6.511}$$

Thus, given that the wave function is a conditional probability, we have in the form of a phasor:

$$\Psi = \Psi_x\Psi_y\Psi_z = c^{te}e^{\mathrm{i}k_x x}e^{\mathrm{i}k_y y}e^{\mathrm{i}k_z z} = c^{te}e^{\mathrm{i}\vec{k}\circ\vec{r}} \tag{9.6.512}$$

And the associated discrete energies are then:

$$E_n = \frac{\hbar^2}{2m}(k_x^2 + k_y^2 + k_z^2) = \frac{\hbar^2\|\vec{k}\|^2}{2m} \tag{9.6.513}$$

The vector $\vec{k}$ is therefore defined by:

$$\vec{k} = \left(n_x\frac{2\pi}{L_x}, n_y\frac{2\pi}{L_y}, n_z\frac{2\pi}{L_z}\right) \tag{9.6.514}$$

Remark

We can easily see that the differences in energy between consecutive levels are all smaller as the dimensions of the black-body (assimilated to a box) L_x,L_y,L_z are larger. For macroscopic dimensions, these differences are totally inappreciable. This observation will allow us a little further to make a small approximation.

Explanation: For an electron ($m \cong 10^{-30}$ [kg]) enclosed in a cubic box of side $L = 1$ [m], the difference between two consecutive levels is:

$$E_{nx+1,ny,nz} - E_{nx,ny,nz} = (2n_x + 1)\frac{2\pi^2\hbar^2}{mL_x^2} \tag{9.6.515}$$

Therefore approximately 10^{-35} [J]...

The vectors $\vec{k}$ that interest us (since each represent respectively a possible micro-state), immersed in the phase space of the wave numbers, have their end situated in one of the nodes of a three-dimensional network constituted by elementary meshes whose edges are parallel to the axes and which measure respectively $2\pi/L_x$, $2\pi/L_y$ and $2\pi/L_z$. We want to evaluate the number of vectors for which this end falls in the interval between the two spheres centered at the origin and radii of standard k and $k+\mathrm{d}k$. The infinitesimal volume of the spherical shell between the two spheres is thus trivially given by:

$$\mathrm{d}V=4\pi k^2\mathrm{d}k \tag{9.6.516}$$

The number of elementary cells (microstates) included in this region of the space of $\vec{k}$ is roughly equal to the number of times its volume contains that of the elementary cell, which is:

$$\frac{2\pi}{L_x}\frac{2\pi}{L_y}\frac{2\pi}{L_z}=\frac{8\pi^3}{V} \tag{9.6.517}$$

We thus obtain the number of micro-states in the volume $\mathrm{d}V$ (hence the density of micro-states):

$$\frac{4\pi k^2\mathrm{d}k}{\dfrac{8\pi^3}{V}}=\frac{Vk^2\mathrm{d}k}{2\pi^2} \tag{9.6.518}$$

We must not forget the following relations (see sections of Wave Mechanics page 3479, Wave Quantum Physics page 4749 and Special Relativity page 5687):

$$k=\frac{2\pi}{\lambda}=\frac{\omega}{c} \tag{9.6.519}$$

Therefore as:

$$k^2=\frac{\omega^2}{c^2} \qquad \mathrm{d}k=\frac{1}{c}\mathrm{d}\omega \tag{9.6.520}$$

and (for recall):

$$\omega=2\pi\nu \tag{9.6.521}$$

Therefore it comes:

$$\frac{Vk^2\mathrm{d}k}{2\pi^2}=\frac{V\omega^2}{2\pi^2c^3}\mathrm{d}\omega=\frac{V4\pi^2\nu^2}{2\pi^2c^3}2\pi\mathrm{d}\nu=\frac{V4\pi^3\nu^2}{\pi^2c^3}\mathrm{d}\nu=\frac{V4\pi\nu^2}{c^3}\mathrm{d}\nu \tag{9.6.522}$$

But when physicists had developed this theoretical model (apparently Bose would have been the first to do so in a modern way), they had noticed that the final result did not correspond to the experience with a factor of 2. From then on, they multiplied empirically the density of micro-states by a factor 2 such that:

$$2\frac{V4\pi\nu^2}{c^3}\mathrm{d}\nu=\frac{V8\pi\nu^2}{c^3}\mathrm{d}\nu \tag{9.6.523}$$

This factor 2 would be explained today (I have never seen the proof of this personally ...) by the spin 1 of the photon. This permits a priori three values for its projection: -1, 0, 1. The value 0

would be forbidden by the quantum theoretical field (if someone has the proof of this statement, I am a taker!).

In a black-body in thermodynamic equilibrium, photons (which are bosons) form a gas whose constituents do not interact chemically with each other. This type of situation is typically described by the Bose-Einstein distribution that we have proved in the section of Statistical Mechanics. Thus, since $\mu=0$, we have in the case of a discrete spectrum of energy states (it is thus here that appears the concept of quantification that Planck had originally introduced by tinkering):

$$n_i=\frac{g_i}{e^{\frac{E_i}{kT}}-1}=\frac{g_i(\nu)}{e^{\frac{h\nu_i}{kT}}-1} \tag{9.6.524}$$

and in a case that we consider as continuous:

$$\mathrm{d}n=\frac{g(\nu)}{e^{\frac{h\nu}{kT}}-1}=\frac{\frac{V8\pi\nu^2}{c^3}\mathrm{d}\nu}{e^{\frac{h\nu}{kT}}-1} \tag{9.6.525}$$

Before continuing it is important for the reader to realize that the analysis of the radiation of the black-body thus comes for the two previous relations to be imposed:

- First a quantification of energy levels in packets $h\nu$ whereas at the time of the discovery of the phenomenon the Nature was considered continuous in all its phenomena.
- Secondly, consider Boltzmann's theory of entropy and the resulting statistical distribution of Bose-Einstein is a pillar of the study of physical systems.

In the black-body, we have for internal energy:

$$U=\sum_i E_i n_i=\int\limits_0^{+\infty} h\nu\frac{\frac{V8\pi\nu^2}{c^3}\mathrm{d}\nu}{e^{\frac{h\nu}{kT}}-1}=V\int\limits_0^{+\infty}\frac{8\pi h}{c^3}\frac{\nu^3}{e^{\frac{h\nu}{kT}}-1}\mathrm{d}\nu \tag{9.6.526}$$

Hence:

$$\frac{U}{V}=\int\limits_0^{+\infty}\frac{8\pi h}{c^3}\frac{\nu^3}{e^{\frac{h\nu}{kT}}-1}\mathrm{d}\nu=\int\limits_0^{+\infty}\rho(\nu,T)\mathrm{d}\nu\;[\mathrm{J}\cdot\mathrm{m}^{-3}] \tag{9.6.527}$$

The radiation of a black-body (its "monochromatic brightness" as some say ...) is thus given by the "Planck's law":

$$\boxed{R(\nu,T)=\frac{8\pi h\nu^3}{c^3}\frac{1}{e^{\frac{h\nu}{kT}}-1}=\frac{2\hbar\omega^3}{\pi c^3}\frac{1}{e^{\frac{\hbar\omega}{kT}}-1}\;[\mathrm{J}\cdot\mathrm{s}\cdot\mathrm{m}^{-3}]} \tag{9.6.528}$$

The first equality is often written in the following form which allows an interpretation of the result:

$$\boxed{R(\nu,T)=\frac{8\pi\nu^2}{c^3}h\nu\frac{1}{e^{\frac{h\nu}{kT}}-1}} \tag{9.6.529}$$

Where:

- $8\pi\nu^2/c^3$ corresponds to the volumetric density of modes of the radiation of the black-body
- $h\nu$ to the mean energy per quantum of energy (!!!!!)
- $\dfrac{1}{e^{\frac{h\nu}{kT}}-1}$ represents the population of the modes

Finally, let us see another common way of writing Planck's law. Since:

$$R(\nu,T)\mathrm{d}\nu=R(\lambda,T)\mathrm{d}\lambda \qquad \text{and} \qquad v=\frac{c}{\lambda}\Rightarrow\frac{\mathrm{d}\nu}{\mathrm{d}\lambda}=\frac{-c}{\lambda^2} \tag{9.6.530}$$

therefore:

$$R(\nu,T)\frac{\mathrm{d}\nu}{\mathrm{d}\lambda}=\frac{-c}{\lambda^2}R(\nu,T)=R(\lambda,T) \tag{9.6.531}$$

but, as $R(\lambda,T)\geq 0$, $R(\nu,T)\geq 0$, it is convenient to take the absolute value:

$$R(\nu,T)\frac{\mathrm{d}\nu}{\mathrm{d}\lambda}=\left|-\frac{c}{\lambda^2}\right|R(\nu,T)=\frac{c}{\lambda}^2R(\nu,T) \tag{9.6.532}$$

Finally, we get another form of Planck's law which expresses the energy flux density for a given wavelength:

$$\boxed{R(\lambda,T)=\frac{8\pi ch}{\lambda^5}\frac{1}{e^{\frac{hc}{\lambda kT}}-1}} \tag{9.6.533}$$

Remark

Max Planck proposed this law by a succession of theoretical trial and errors and analogies in 11900 (holocene calendar) without knowing the statistical distribution of Bose-Einstein which is remarkable experimentally speaking!

If $h\nu\ll kT$ (hence in the domain of long wavelengths), the Taylor development of e^x for small x (see section Sequences and Series page 1703) gives:

$$e^x=1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\ldots\cong 1+x \tag{9.6.534}$$

Which gives us:

$$e^{\frac{hc}{\lambda kT}}\cong 1+\frac{hc}{\lambda kT} \tag{9.6.535}$$

and the Planck's law thus becomes the "Rayleigh-Jeans law" (which had been discovered before Planck's law):

$$\boxed{R(\lambda,T)=\frac{8\pi h}{\lambda^3}\frac{1}{\dfrac{hc}{\lambda kT}}=\frac{8\pi h}{\lambda^3}\frac{\lambda kT}{hc}=\frac{8\pi}{\lambda^2}\frac{kT}{c}} \tag{9.6.536}$$

That can also sometimes be found in the specialized literature in the form:

$$R(\nu,T)=\frac{8\pi}{\left(\dfrac{c}{\nu}\right)^2}\frac{kT}{c}=\frac{8\pi\nu^2}{c^3}kT \tag{9.6.537}$$

Conversely, if $h\nu \gg kT$ we have:

$$e^{\frac{hc}{\lambda kT}} - 1 \cong e^{\frac{hc}{\lambda kT}} \tag{9.6.538}$$

And the Planck's law therefore becomes:

$$\boxed{R(\lambda,T) = \frac{8\pi h}{\lambda^3}\frac{1}{e^{\frac{hc}{\lambda kT}}} = \frac{8\pi h}{\lambda^3}e^{-\frac{hc}{\lambda kT}}} \tag{9.6.539}$$

Which is nothing but the "Wien's first law" (which had been discovered before the Rayleigh-Jeans law). This law effectively describes the presence of a maximum of radiation, but contrary to the Rayleigh-Jeans law, it provides false values for large wavelengths (i.e. small frequencies). Moreover, it implies that the intensity of radiation tends towards zero with the increase of the temperature, which also contradicts the experiment.

Here is a diagram showing the differences between the three laws at 300 Kelvins:

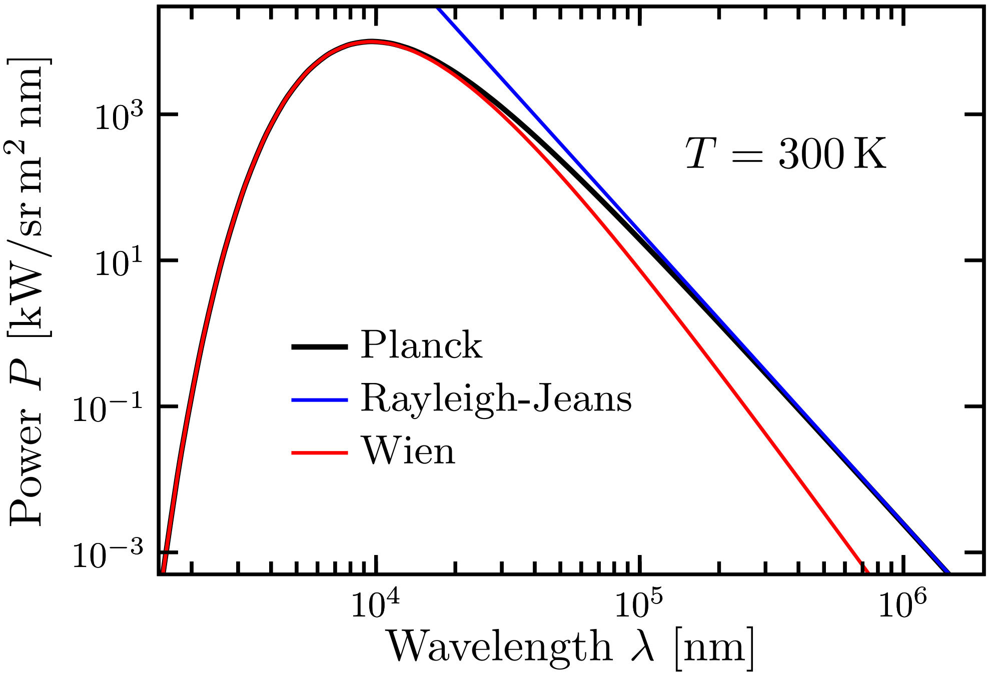

Figure 9.177: **Plot of the three radiation laws (Planck's, Rayleigh-Jeans, Wien) in a log-log scale for comparison (author: Izaak Neutelings)**

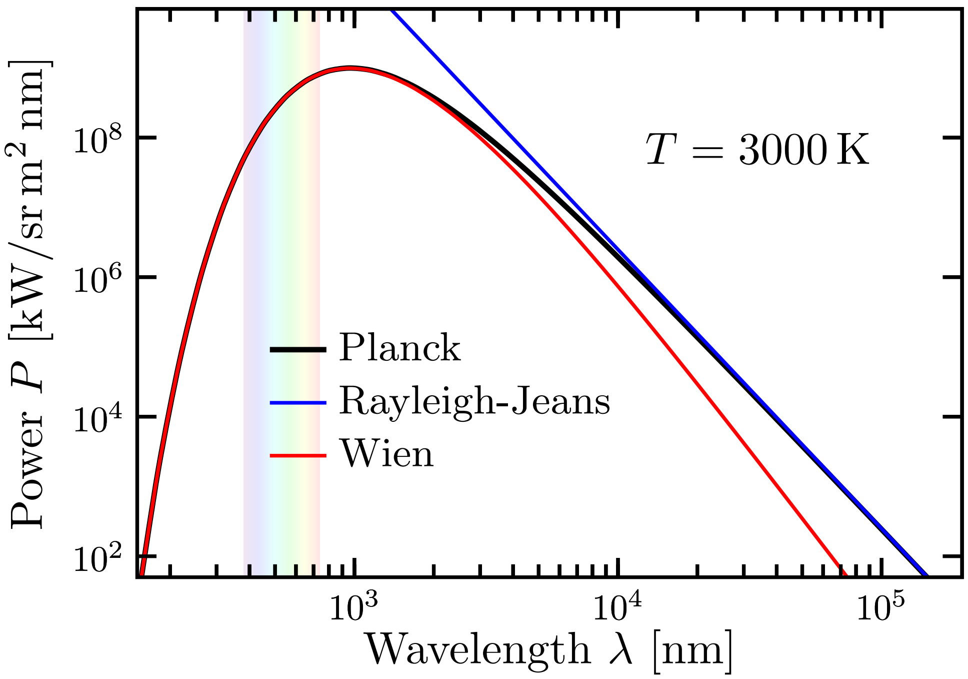
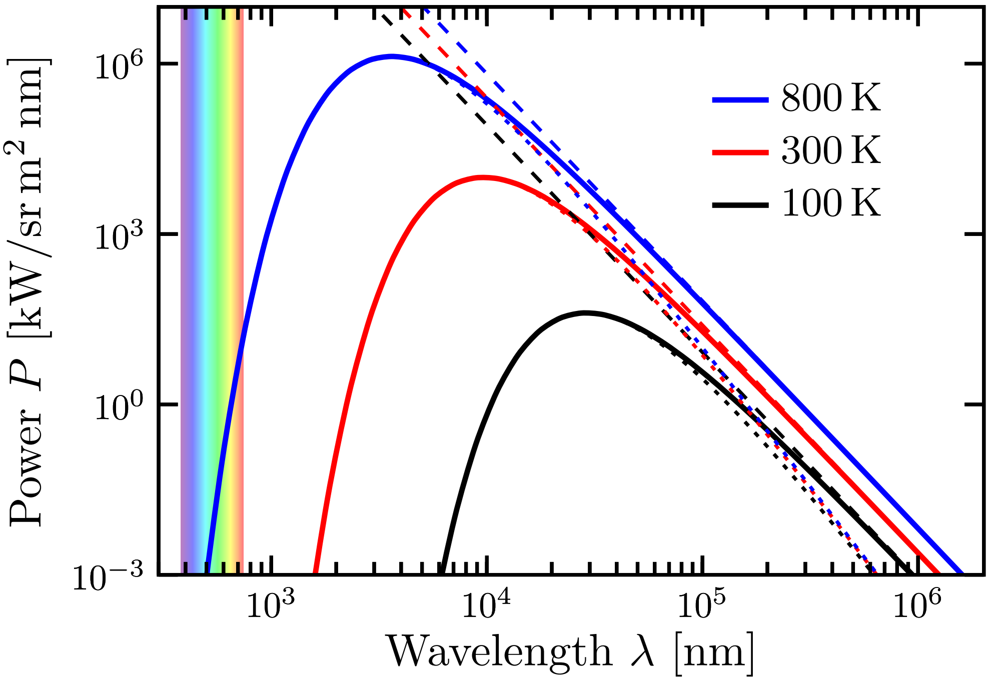
And the same kind of plot at $3,000$ Kelvins:



Or for various temperatures:



We see above that the Rayleigh-Jeans was good at low frequencies whereas that of Wien was good at the highs. Historically it took numerous tests and quite a few years to the physicists to find the adequate model that finally led Max Planck to consider the quantification of the states of energy (which he did not realize himself only quite a long time after having elaborated his model).

Another form of the previous diagram only showing the Rayleigh-Jean law and Planck's law in function of wavelength rather than in frequencies is most well known:

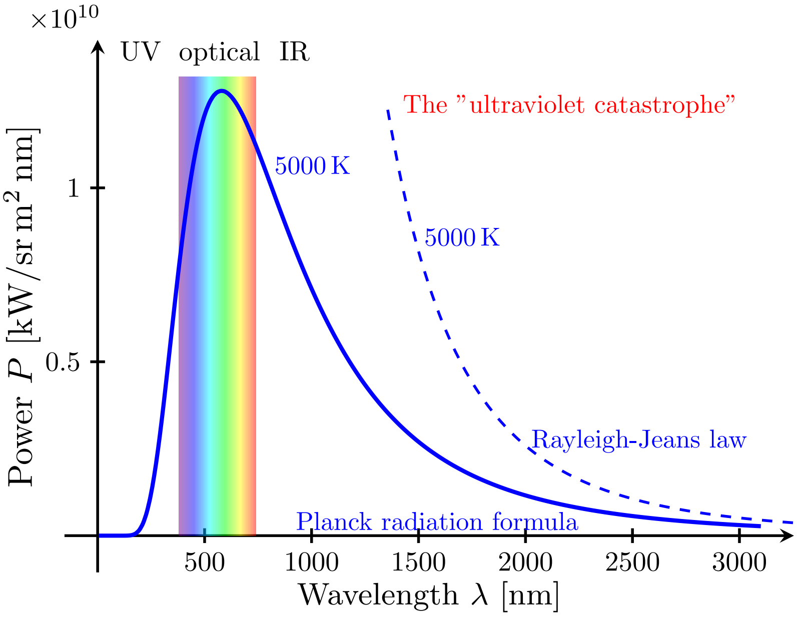


Figure 9.178: Plot of Planck's and Rayleigh-Jeans law (author: Izaak Neutelings)

as it highlights the "ultraviolet catastrophe", also named the "Rayleigh–Jeans catastrophe". Indeed, it was the prediction of late 119th century/early 120th century (holocene calendar) classical physics , based on mathematical developments of Rayleigh and Jeans using the equipartition theorem (see section Continuum Mechanics page 3902), that an ideal black-body at thermal equilibrium will emit radiation in all frequency ranges, emitting more energy as the frequency increases. By calculating the total amount of radiated energy, (i.e., the sum of emissions in all frequency ranges), it can be shown that a black-body would release an infinite amount of energy, contradicting the principles of conservation of energy and indicating that a new model for the behaviour of black bodies was needed.

Remark

Many popular histories of physics, as well as a number of physics textbooks, present an incorrect version of the history of the ultraviolet catastrophe. In that version, the "catastrophe" was first noticed by Planck, who developed his formula in response. In fact Planck never concerned himself with this aspect of the problem, because he did not think that the equipartition theorem (see section Continuum Mechanics page 3902) was fundamental – his motivation for introducing "quanta" was entirely different. That Planck's proposal happened to provide a solution for it was realized only later, as stated above. Though the true sequence of events has been known to historians for many decades, the historically incorrect version persists, in part because Planck's actual motivations for the proposal of the quantum are complicated and difficult to summarize for a lay audience.

We can also prove again the Stefan's law (we have already done this but with another approach) but this time by explaining the origin of the Stefan-Boltzmann constant $\sigma_{\text{S.B.}}$.

Let us first recall that the energy flux (see section Geometric Optics page 4343) is given by:

$$\mathrm{d}\Phi=L(\theta)\mathrm{d}S\mathrm{d}\Omega\cos(\theta) \qquad (9.6.540)$$

Since the luminance depends on the frequency and therefore the temperature of the emitter body, we can add:

$$\mathrm{d}\Phi(\nu,T)=L(\theta,\nu,T)\mathrm{d}S\mathrm{d}\Omega\cos(\theta)\mathrm{d}\nu \qquad (9.6.541)$$

The energy radiated through a given elementary surface $\mathrm{d}S\cos(\theta)$ is therefore:

$$\mathrm{d}\Phi(\nu,T)\mathrm{d}\nu\mathrm{d}t=L(\theta,\nu,T)\mathrm{d}S\mathrm{d}\Omega\cos(\theta)\mathrm{d}\nu\mathrm{d}t \qquad (9.6.542)$$

If the volume of emission is considered as an elementary volume assimilated to a cylinder of height $c\mathrm{d}t$ and of roof having for surface $\mathrm{d}S\cos(\theta)$ (see section Geometric Optics page ??) the energy density per unit of frequency and steradian is then given by:

$$\mathrm{d}U(\nu,T)=\frac{L(\theta,\nu,T)\mathrm{d}S\mathrm{d}\Omega\cos(\theta)\mathrm{d}\nu\mathrm{d}t}{c\mathrm{d}t\mathrm{d}S\cos(\theta)}=\frac{1}{c}L(\theta,\nu,T)\mathrm{d}\Omega\mathrm{d}\nu \qquad (9.6.543)$$

Given the isotropy of the black-body at equilibrium, we have by integrating on the whole of the solid angle the energy density per unit of frequency only:

$$\mathrm{d}U(\nu,T)=\frac{4\pi}{c}L(\theta,\nu,T)\mathrm{d}\nu \qquad (9.6.544)$$

Dimensional analysis gives us:

$$\frac{4\pi}{c}L(\theta,\nu,T)=R(\nu,T)\Leftrightarrow L(\theta,\nu,T)=\frac{c}{4\pi}R(\nu,T) \qquad (9.6.545)$$

Finally, it is useful to consider the total power emitted per unit area (i.e. emittance):

$$\mathrm{d}M(\nu,T)=L(\theta)\mathrm{d}\Omega\cos(\theta) \qquad (9.6.546)$$

If we integrate on the half surface of a sphere (relatively to the surface point of the emitter):

$$\mathrm{d}M(\nu,T)=\int\limits_0^{2\pi}L(\theta)\mathrm{d}\Omega\cos(\theta)=\int\limits_0^{2\pi}L(\theta)\cos(\theta)(2\pi\sin(\theta)\mathrm{d}\theta) \qquad (9.6.547)$$

Indeed for a sphere (see section Trigonometry page 2549):

$$\mathrm{d}\Omega=2\pi\sin(\theta)\mathrm{d}\theta \qquad (9.6.548)$$

Since the luminance is independent of θ (isotropy of the radiation of the black-body), integration is elementary, and we find:

$$M(\nu,T)=\pi L=\pi\frac{c}{4\pi}R(\nu,T)=\frac{c}{4}R(\nu,T)\;[\mathrm{J}\cdot\mathrm{m}^{-2}] \qquad (9.6.549)$$

The total emittance is then given by:

$$\boxed{M(T)=\frac{c}{4}\int\limits_0^{+\infty}R(\nu,T)\mathrm{d}\nu=\frac{c}{4}\int\limits_0^{+\infty}\frac{h\nu^3}{c^3}\frac{1}{e^{\frac{h\nu}{kT}}-1}\mathrm{d}\nu=2\pi\frac{h}{c^2}\int\limits_0^{+\infty}\frac{\nu^3}{e^{\frac{h\nu}{kT}}-1}\mathrm{d}\nu} \qquad (9.6.550)$$

Remark

We will see in the section of Optics (ray optics) at the page 4340, how we can deduce the corresponding number of photons for important calculations about CCD (semiconductor Charge-Coupled Devices) cameras.

By putting $x=h\nu/kT$, we can simplify the integrand so that:

$$M(T)=\frac{2\pi h}{c^2}\frac{(kT)^4}{h^4}\int\limits_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x=\frac{2\pi h}{c^2}\frac{(kT)^4}{h^4}\left(\frac{\pi^4}{15}\right)=\frac{2\pi^5k^4}{15c^2h^3}T^4 \tag{9.6.551}$$

Let us prove, because its far to be easy that:

$$\int\limits_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x=\frac{\pi^4}{15} \tag{9.6.552}$$

Let us write the integrand in the following form:

$$x^3(e^x-1)^{-1}=x^3e^{-x}(e^x-1)^{-1}e^x=x^3e^{-x}(1-e^{-x})^{-1} \tag{9.6.553}$$

For the term:

$$\frac{1}{1-e^{-x}} \tag{9.6.554}$$

Let us put $t=e^{-x}$, then we have:

$$\frac{1}{1-t} \tag{9.6.555}$$

And we have proved in the section of Functional Analysis, using results of the section Sequences and Series, that under the condition $|t|<1$, the last fraction can be written:

$$\frac{1}{1-t}=\sum_{n=0}^{+\infty}t^n=1+t+t^3+\ldots \tag{9.6.556}$$

Since then:

$$x^3e^{-x}(1-e^{-x})^{-1}=x^3e^{-x}(1+e^{-x}+e^{-2x}+e^{-3x}+\ldots)=x^3e^{-x}+x^3e^{-2x}+x^3e^{-3x}+\ldots \tag{9.6.557}$$

Hence:

$$\int\limits_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x=\int\limits_0^{+\infty}\left(x^3e^{-x}+x^3e^{-2x}+x^3e^{-3x}+\ldots\right)\mathrm{d}x \tag{9.6.558}$$

We can therefore replace our integral by a sum of defined integrals. We see that by making integrations by successive parts, we get:

$$\begin{aligned}\int_0^{+\infty} x^3 e^{-nx}\mathrm{d}x &= -\frac{1}{n}\left[x^3e^{-nx}\right]_0^{+\infty}+\frac{1}{n}\int_0^{+\infty}3x^2e^{-nx}\mathrm{d}x=\frac{3}{n}\int_0^{+\infty}x^2e^{-nx}\mathrm{d}x\\ &=-\frac{3}{n^2}\left[x^2e^{-nx}\right]_0^{+\infty}+\frac{3}{n^2}\int_0^{+\infty}2xe^{-nx}\mathrm{d}x=\frac{3}{n^2}\int_0^{+\infty}2xe^{-nx}\mathrm{d}x\\ &=-\frac{6}{n^3}\left[xe^{-nx}\right]_0^{+\infty}+\frac{6}{n^3}\int_0^{+\infty}e^{-nx}\mathrm{d}x=\frac{6}{n^3}\int_0^{+\infty}e^{-nx}\mathrm{d}x=\frac{6}{n^3}\left[-\frac{1}{n}e^{-nx}\right]_0^{+\infty}\\ &=-\frac{6}{n^4}\left[e^{-nx}\right]_0^{+\infty}=-\frac{6}{n^4}\left(e^{-\infty x}-e^{-0x}\right)=-\frac{6}{n^4}(0-1)=\frac{6}{n^4}\end{aligned}\tag{9.6.559}$$

Therefore:

$$\int_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x=6\left(1+\frac{1}{2^4}+\frac{1}{3^4}+\frac{1}{4^4}+\ldots\right)=6\sum_{n=1}^{+\infty}\frac{1}{n^4}\tag{9.6.560}$$

However, we have proved in the section of Sequences and Series in our study of the Riemann zeta function that:

$$\zeta(4)=\sum_{n=1}^{+\infty}\frac{1}{n^4}=\frac{\pi^4}{90}\tag{9.6.561}$$

Therefore:

$$\int_0^{+\infty}\frac{x^3}{e^x-1}\mathrm{d}x=6\sum_{n=1}^{+\infty}\frac{1}{n^4}=6\zeta(4)=\frac{6\pi^4}{90}=\frac{\pi^4}{15}\tag{9.6.562}$$

Finally, the Stefan-Boltzmann constant can be expressed analytically in the form:

$$\boxed{\sigma\cong\frac{2\pi^5k^4}{15c^2h^3}=\frac{\pi^2k^4}{60c^2\hbar^2}=5.67051\cdot10^{-8}\,[\mathrm{W}\cdot\mathrm{m}^{-2}\cdot\mathrm{K}^4]}\tag{9.6.563}$$

Honestly ... it was hard to guess ... It must be notice that since Planck's constant was not introduced until a couple decades after the Stefan-Boltzmann law was developed, one might more appropriately say that the Stefan-Boltzmann constant pins down Planck's constant.

For summary, we have then:

$$\boxed{M(T)=\frac{2\pi^5k^4}{15c^2h^3}T^4=\sigma T^4\qquad\text{and}\qquad\rho(T)=\frac{4}{c}M(T)=\frac{8\pi^5k^4}{15c^3h^3}T^4=\sigma_{\text{S.B.}}T^4}\tag{9.6.564}$$

where the relation on the left is the famous "Stefan-Boltzmann law".

Let us determine now for what frequency we have the maximum energy density. In other words, this is equivalent to seek where the derivative:

$$\frac{\mathrm{d}R(\nu,T)}{\mathrm{d}\nu}=\frac{\mathrm{d}}{\mathrm{d}\nu}\left(8\pi\frac{h\nu^3}{c^3}\frac{1}{e^{\frac{h\nu}{kT}}-1}\right) \tag{9.6.565}$$

cancels. Therefore:

$$\frac{\mathrm{d}R(\nu,T)}{\mathrm{d}\nu}=\frac{8\cdot 3\pi h\nu^3}{c^3}\frac{1}{e^{\frac{h\nu}{kT}}-1}-8\pi\frac{h\nu^3}{c^3}\frac{h}{kT}\frac{e^{\frac{h\nu}{kT}}}{\left(e^{\frac{h\nu}{kT}}-1\right)^2} \tag{9.6.566}$$

Let us divide by $R(\nu,T)$:

$$\begin{aligned}&\frac{1}{R(\nu,T)}\frac{\mathrm{d}R(\nu,T)}{\mathrm{d}\nu}=\frac{3}{\nu}-\frac{h}{kT}\frac{e^{\frac{h\nu}{kT}}}{e^{\frac{h\nu}{kT}}-1}=0\Rightarrow\frac{3}{\nu}e^{\frac{h\nu}{kT}}-\frac{3}{\nu}-\frac{h}{kT}e^{\frac{h\nu}{kT}}=0\\&\Rightarrow\frac{3}{\nu}-\frac{3}{\nu}e^{-\frac{h\nu}{kT}}-\frac{h}{kT}=0\Leftrightarrow e^{-\frac{h\nu}{kT}}=1-\frac{1}{3}\frac{h\nu}{kT}\end{aligned} \tag{9.6.567}$$

The last relation admits a single positive root that we can determine with Maple™ 4.00b using the command:

```
>evalf(solve(exp(-x)-1+1/3*x=0,x));
```

$$\frac{h\nu}{kT}=2.82144 \tag{9.6.568}$$

What gives us the "Wien's second law" or "Wien's law of displacement" which says that as the temperature of a black-body increases, the wavelength at which the intensity of the radiation Is the strongest becomes shorter and shorter:

$$\boxed{\nu_{\max}=2.82144\frac{kT}{h}=a\frac{kT}{h}} \tag{9.6.569}$$

where a is named the "Wien's constant". The latter is often rearranged and condensed as following:

$$T=\frac{2,897.8\cdot 10^{-6}\,[\mathrm{m}\cdot\mathrm{K}]}{\lambda_{\max}} \tag{9.6.570}$$

The figure below shows this result using the logarithmic scales:

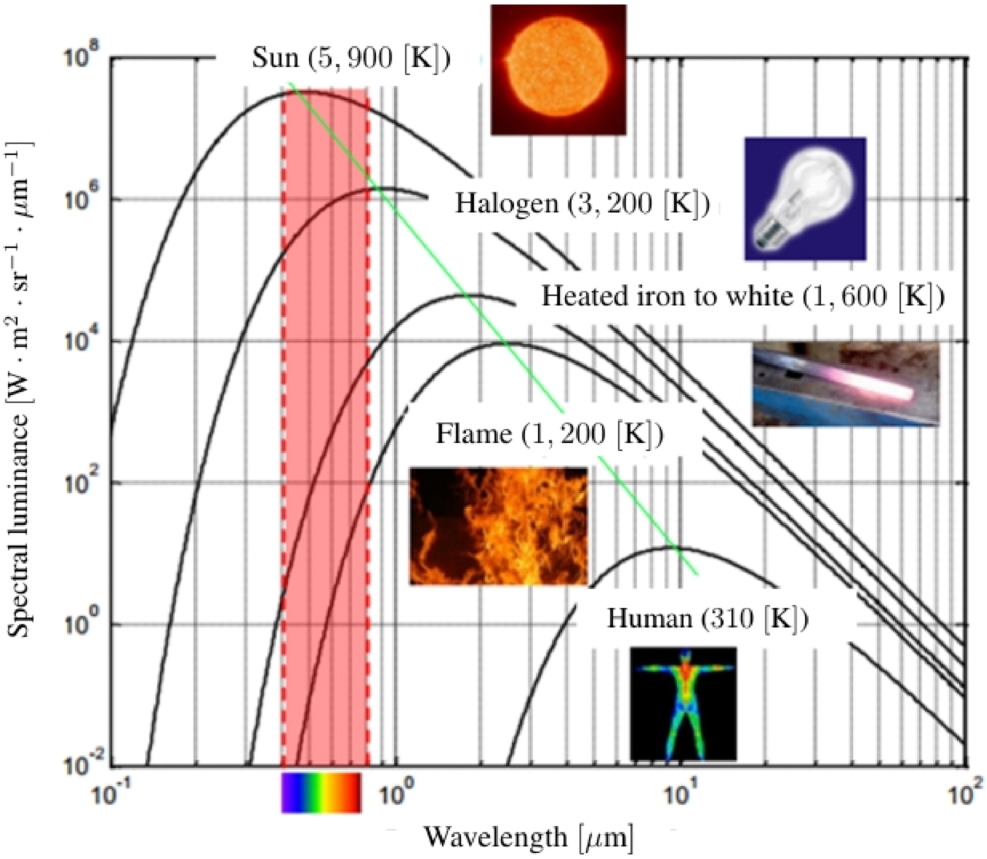

Figure 9.179: Representation of Planck's law (distribution) with Wien's displacement

Thus, not only does the increase in temperature lead to an increase in the total amount of radiated energy but the Wien displacement law tells us that the wavelength at which the maximum amount of radiation is emitted multiplied by the temperature of the black-body is always a constant (or otherwise seen: the maximum wavelength is inversely proportional to the temperature as shown in the green line in the figure above)! This is an extremely simple result that tells us two important things:

1. If the temperature doubles, then the maximum wavelength will be half the previous wavelength.
2. If we know the constant (which is our case) then we can calculate the maximum wavelength for any temperature at which a black-body can be found.

It is easy to understand now why any material at low temperatures emits mainly long wavelength radiation in the infra-red part of the spectrum and as the temperature rises, there is more radiated energy in each region of the spectrum and the wavelength peak decreases as it moves toward shorter wavelengths. As a result, the color of the emitted light changes from red to orange, then yellow to bluish-white (and further into the ultraviolet).

Remark

Obviously the second Wien's law is also sometimes given in the literature not in function of the frequency, but to in function of the wavelength ...

Let us insist on the fact that the Planck's law is valid only in the cases where the radiation is in thermal equilibrium. This restriction is important in practice since the phenomena of emission or absorption of radiation by the material occur most often under conditions out of equilibrium: in the case, for example, of lighting by an electric lamp or electric heating by infra-red radiation, the is an irreversible (and therefore out of equilibrium) transformation of electrical energy into radiation energy. Similarly, solar radiation is produced by the nuclear reactions which take place inside the Sun (actually a G2V-type star, aka yellow dwarf) and which gradually consume its substance; At the microscopic level also, the emission of a photon by an excited atom is very often an irreversible return of the atom to its fundamental state (spontaneous emission out of equilibrium). In the case of the black-body, on the contrary, the radiation is confined within a closed enclosure (we eventually leave a negligible fraction of this radiation to escape outside to be subjected to the measurements) and we can thus achieve thermal equilibrium with the walls.

Planck's law, which we have demonstrated above, is perfectly verified by experience in the whole range of temperatures accessible at this date for a black-body and remains a quite good approximation also for Stars and other objects that are not at equilibrium:

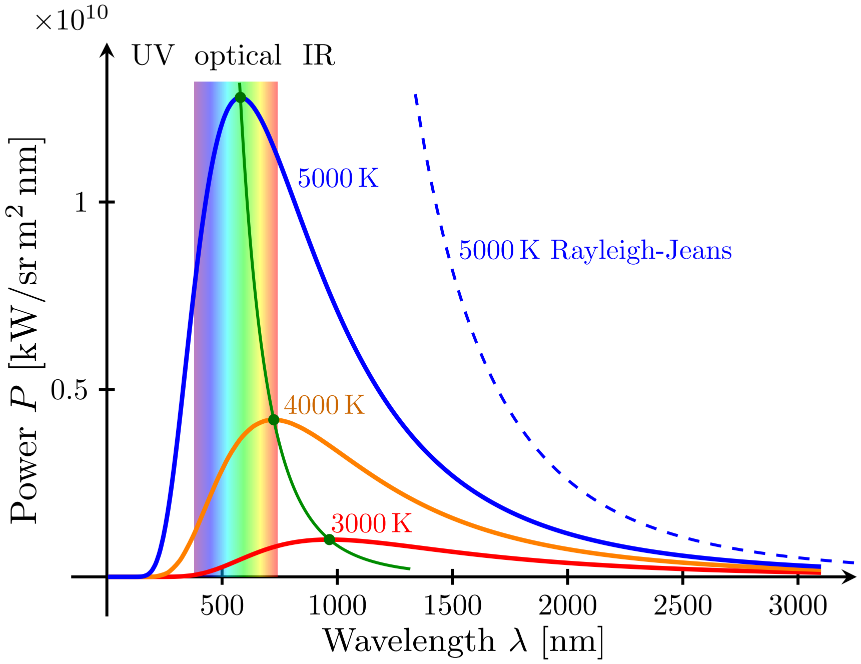

Figure 9.180: Planck's law at various temperatures in function of wave length (source: ?)

We notice from the graph above that a body heated above $5,000$ [K] has an emission peak in the middle of the visible spectrum. In the field of colorimetry, we associate a temperature with a color by looking for the temperature of the black-body for which the peak of radiation has its maximum in the wavelength of the given color. Another typical representation (and more complete) for the Sun is the following (TAO on this figure means: Top Of Atmosphere):

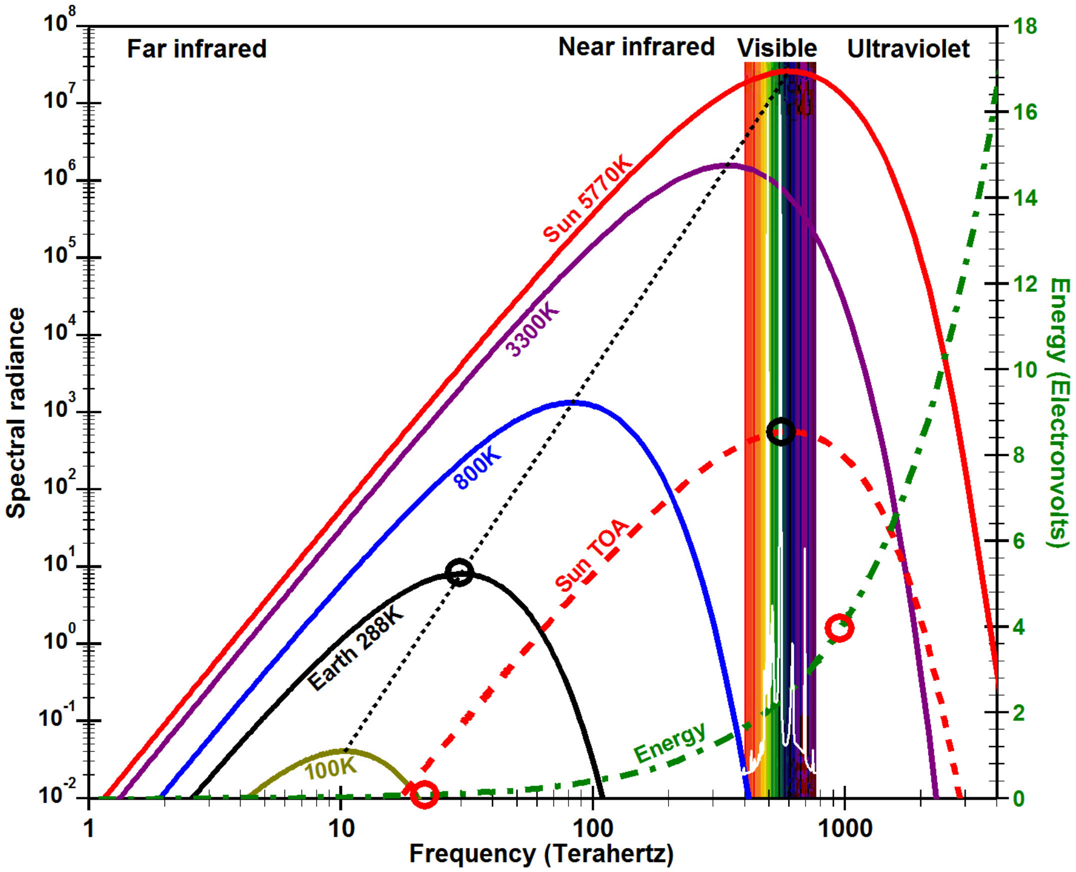

Figure 9.181: Sun's radiation spectrum in function of frequency and logarithmic scale (source: ?)

Or a more detailed Sun spectrum at sea level:

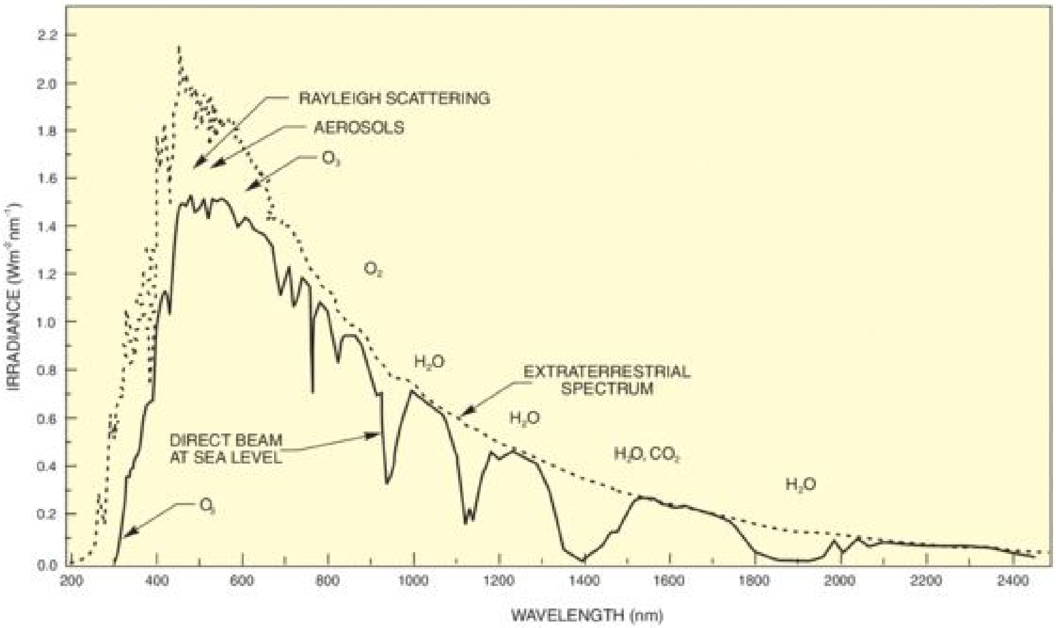

Figure 9.182: Sun's radiation spectrum in function of frequency at sea level (source: ?)

It should be notice that many light sources emit a luminous flux that does not follow the law of the black-body (a bulb filament, for example) and that the Wien law does not apply to them. On the other hand, it remains true that they emit at a wavelength all the shorter as they are hot.

It should also be keep in mind that the luminous flux coming from an object is not necessarily of a thermal nature! In other words its color does not always indicate its temperature. For example, the color of the sky comes from blue sunlight diffused by the air (Rayleigh scattering), and not from a hypothetical temperature of $15,000$ [K]. Similarly a tree is green, not because it is $8,000$ [K] hot, but because it reflects the green light that makes up the light of day...

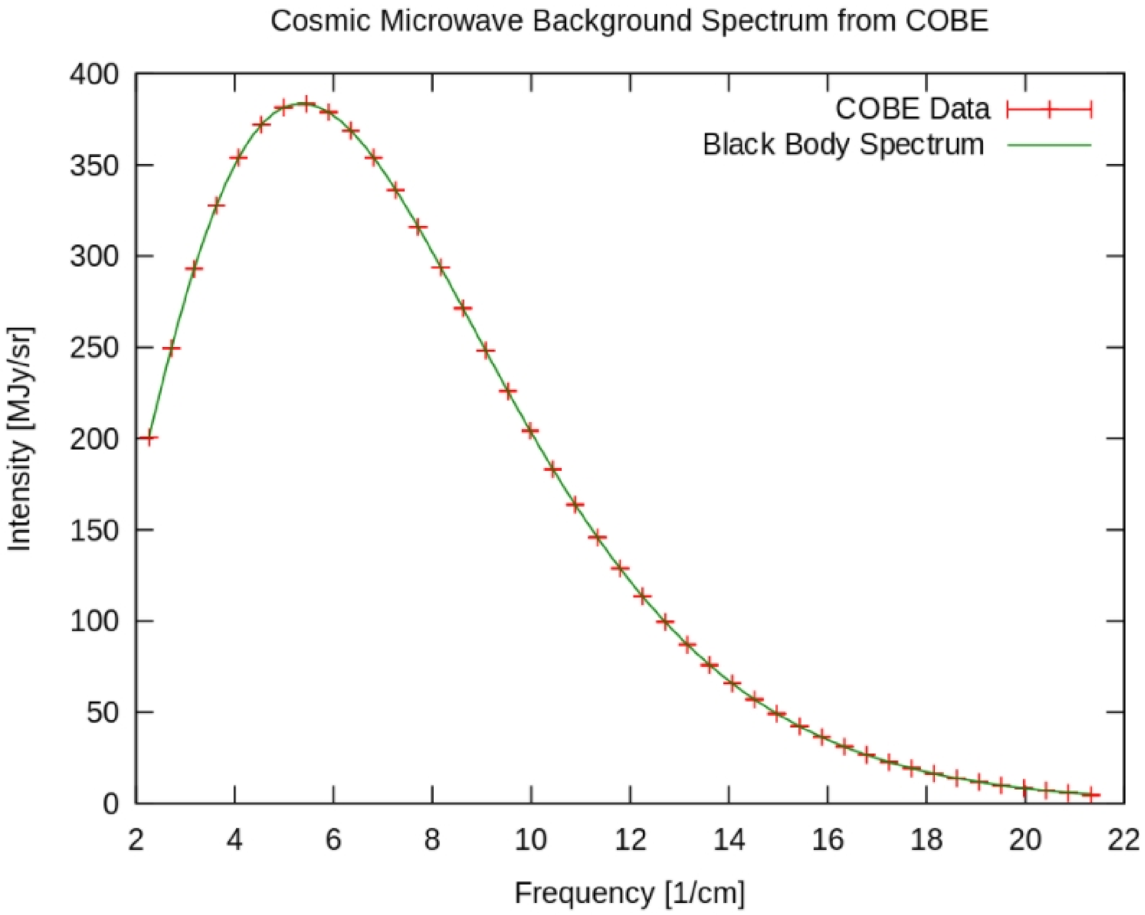

Figure 9.183: Comparison of theoretical black-body and our Universe cosmic microwave background (source: Wikipedia)

9.6.12.2 Summing up all types of heat transfer

So we have seen earlier above the definition that the rate at which the temperature of a solid object of mass m [kg] and specific heat capacity C_p $[\mathrm{J}\cdot\mathrm{kg}^{-1}\cdot\mathrm{K}^{-1}]$ will change $\mathrm{d}T/\mathrm{d}t$ $[\mathrm{K}\cdot\mathrm{s}^{-1}]$ is written as below (see page 3684):

$$mC_p\frac{\mathrm{d}T}{\mathrm{d}t}=\dot{q} \tag{9.6.571}$$

The term $\dot{q}\,[\mathrm{J}\cdot\mathrm{s}^{-1}]$ is the rate at which heat enters (to heat up) or leaves (to cool down) the object.

To start, let us assume the object is initially at T_o and the surroundings is held at constant T_s.

Let us enumerate the different types of heat flows we have seen so far:

1. Heat can enter/leave the object by radiation to a surrounding fluid (gas or liquid). The radiation rate is proportional to the fourth power of absolute temperature $\dot{q}_r \propto T^4$. The initial overall rate of heat transfer is expressed to first order as below (see page 3706):

   $$\dot{q}_{rT} \propto \left|T_o^4 - T_s^4\right|$$

   We can use this to determine the initial temperatures of the object where the cold object receives more radiation heat flow from the surroundings than the hot object looses by radiation heat flow to the surroundings. Thus, we can determine for which cases a cold or hot object changes temperature faster than a hot object in the same air temperatures.

2. Heat can enter/leave the object by convection when the surroundings is a fluid (gas or liquid). The rate of heat transfer is proportional to temperature difference. The net rate of heat transfer by convection is determined as below (see page 3635):

   $$\dot{q}_{hT} \propto |T_o - T_s|$$

   We learn from this that a hot or cold object will cool or heat by convection at the same rate as long as the temperature difference between the object and the surrounding fluid is the same.

3. Finally, heat can enter/leave the object to the surroundings by conduction in the surroundings. This happens with a temperature gradient $\mathrm{d}T_s/\mathrm{d}z\,[\mathrm{K}\cdot\mathrm{m}^{-1}]$ in the surroundings. A fluid does not typically sustain a temperature gradient well; the gradient dissipates and the flow is by convection. Therefore making a statement that you want to consider conduction in the surroundings is akin to saying that you define the surroundings also as a solid. The net rate of conductive flow is written as below (see page 3684):

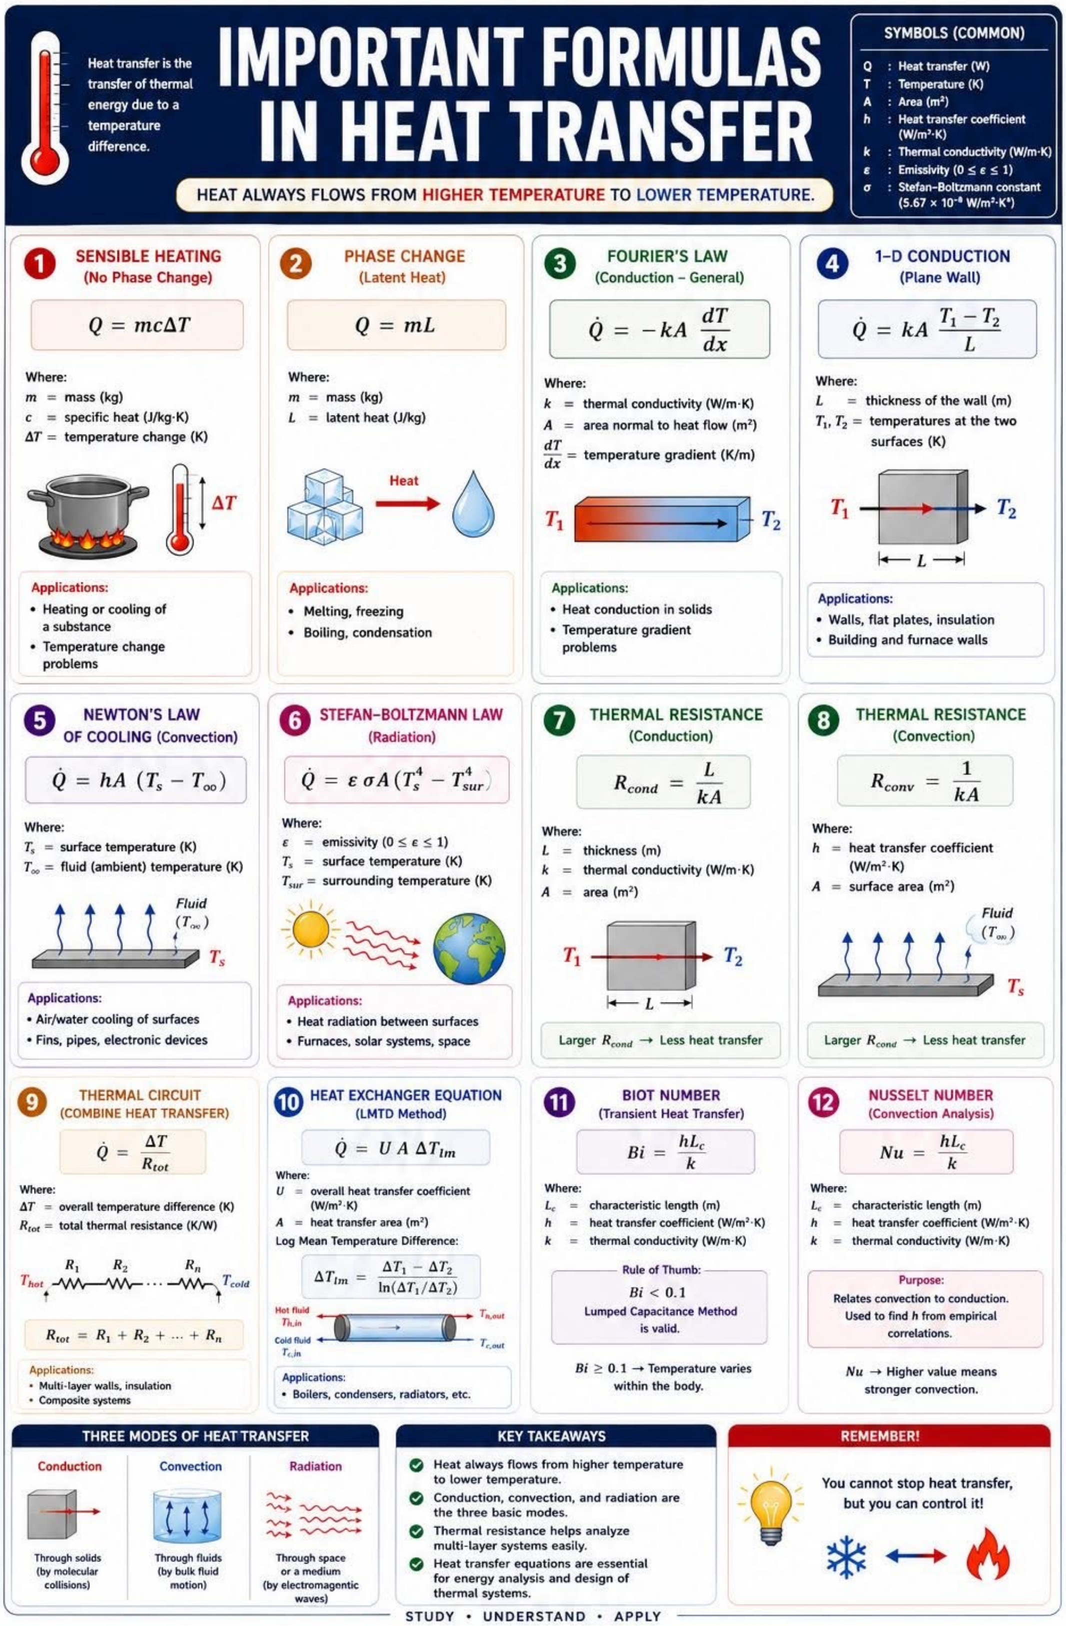
   $$\dot{q}_{kT} \propto |\mathrm{d}T_s/\mathrm{d}z|$$

Combining we get:

$$\boxed{mC_p\frac{\mathrm{d}T_o}{\mathrm{d}t} = \sigma S\left(\varepsilon_s T_s^4 - \varepsilon_o T_o^4\right) + h_s A\left(T_s - T_o\right) - k_s A\frac{\mathrm{d}T_s}{\mathrm{d}z}} \tag{9.6.572}$$

The various terms include the Stefan-Boltzmann factor σ, object area S, convection coefficient h_s, and thermal conductivity k_s. This equation defines the rate of temperature change of the object at any point in time. The $/pm$ signs are set so that, when the object is hotter than the surroundings, the object will cool down (and vice-versa). It is a rather unwieldy equation that is typically solved by considering only one of the three cases (radiation, convection, or conduction) at a time. It also presumes the object heats or cools uniformly throughout. The case when we have a thermal gradient in the solid object is yet another equation.

As a general rule, the rate at which a hot object changes temperature (cools down) cannot be stated to be faster (or slower) than the rate at which a cold object changes temperature (heats up). The rate of heat transfer depends on the type of surroundings (vacuum, fluid, or solid), the temperature of the surroundings, and the type of heat transfer (radiation, convection, or conduction)!



Heat transfer is the transfer of thermal energy due to a temperature difference.

IMPORTANT FORMULAS IN HEAT TRANSFER

HEAT ALWAYS FLOWS FROM HIGHER TEMPERATURE TO LOWER TEMPERATURE.

SYMBOLS (COMMON)

Q : Heat transfer (W)
T : Temperature (K)
A : Area (m²)
h : Heat transfer coefficient (W/m²·K)
k : Thermal conductivity (W/m·K)
ε : Emissivity ($0 \le \varepsilon \le 1$)
σ : Stefan–Boltzmann constant (5.67×10^{-8} W/m²·K⁴)

① SENSIBLE HEATING (No Phase Change)

$$Q = mc\Delta T$$

Where:
m = mass (kg)
c = specific heat (J/kg·K)
ΔT = temperature change (K)

Applications:
- Heating or cooling of a substance
- Temperature change problems

② PHASE CHANGE (Latent Heat)

$$Q = mL$$

Where:
m = mass (kg)
L = latent heat (J/kg)

Applications:
- Melting, freezing
- Boiling, condensation

③ FOURIER'S LAW (Conduction – General)

$$\dot{Q} = -kA\,\frac{dT}{dx}$$

Where:
k = thermal conductivity (W/m·K)
A = area normal to heat flow (m²)
$\frac{dT}{dx}$ = temperature gradient (K/m)

Applications:
- Heat conduction in solids
- Temperature gradient problems

④ 1–D CONDUCTION (Plane Wall)

$$\dot{Q} = kA\,\frac{T_1 - T_2}{L}$$

Where:
L = thickness of the wall (m)
T_1, T_2 = temperatures at the two surfaces (K)

Applications:
- Walls, flat plates, insulation
- Building and furnace walls

⑤ NEWTON'S LAW OF COOLING (Convection)

$$\dot{Q} = hA\,(T_s - T_{oo})$$

Where:
T_s = surface temperature (K)
T_∞ = fluid (ambient) temperature (K)

Applications:
- Air/water cooling of surfaces
- Fins, pipes, electronic devices

⑥ STEFAN–BOLTZMANN LAW (Radiation)

$$\dot{Q} = \varepsilon\,\sigma A\,(T_s^4 - T_{sur}^4)$$

Where:
ε = emissivity ($0 \le \varepsilon \le 1$)
T_s = surface temperature (K)
T_{sur} = surrounding temperature (K)

Applications:
- Heat radiation between surfaces
- Furnaces, solar systems, space

⑦ THERMAL RESISTANCE (Conduction)

$$R_{cond} = \frac{L}{kA}$$

Where:
L = thickness (m)
k = thermal conductivity (W/m·K)
A = area (m²)

Larger R_{cond} → Less heat transfer

⑧ THERMAL RESISTANCE (Convection)

$$R_{conv} = \frac{1}{kA}$$

Where:
h = heat transfer coefficient (W/m²·K)
A = surface area (m²)

Larger R_{cond} → Less heat transfer

⑨ THERMAL CIRCUIT (COMBINE HEAT TRANSFER)

$$\dot{Q} = \frac{\Delta T}{R_{tot}}$$

Where:
ΔT = overall temperature difference (K)
R_{tot} = total thermal resistance (K/W)

$$R_{tot} = R_1 + R_2 + \dots + R_n$$

Applications:
- Multi-layer walls, insulation
- Composite systems

⑩ HEAT EXCHANGER EQUATION (LMTD Method)

$$\dot{Q} = U\,A\,\Delta T_{lm}$$

Where:
U = overall heat transfer coefficient (W/m²·K)
A = heat transfer area (m²)

Log Mean Temperature Difference:

$$\Delta T_{lm} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1/\Delta T_2)}$$

Applications:
- Boilers, condensers, radiators, etc.

⑪ BIOT NUMBER (Transient Heat Transfer)

$$Bi = \frac{hL_c}{k}$$

Where:
L_c = characteristic length (m)
h = heat transfer coefficient (W/m²·K)
k = thermal conductivity (W/m·K)

Rule of Thumb:
$Bi < 0.1$
Lumped Capacitance Method is valid.

$Bi \ge 0.1$ → Temperature varies within the body.

⑫ NUSSELT NUMBER (Convection Analysis)

$$Nu = \frac{hL_c}{k}$$

Where:
L_c = characteristic length (m)
h = heat transfer coefficient (W/m²·K)
k = thermal conductivity (W/m·K)

Purpose:
Relates convection to conduction. Used to find h from empirical correlations.

Nu → Higher value means stronger convection.

THREE MODES OF HEAT TRANSFER

Conduction	Convection	Radiation
Through solids (by molecular collisions)	Through fluids (by bulk fluid motion)	Through space or a medium (by electromagentic waves)

KEY TAKEAWAYS

- ✓ Heat always flows from higher temperature to lower temperature.
- ✓ Conduction, convection, and radiation are the three basic modes.
- ✓ Thermal resistance helps analyze multi-layer systems easily.
- ✓ Heat transfer equations are essential for energy analysis and design of thermal systems.

REMEMBER!

You cannot stop heat transfer, but you can control it!

9.7. Continuum Mechanics

IN a strict sense, Continuum Mechanics is the branch of mechanics that has for purpose the study of motion, deformation and stress fields inside continuum materials whether they are solids, liquids, gases or plasmas.

Modelling an object as a continuum assumes that the substance of the object completely fills the space it occupies. Modelling objects in this way ignores the fact that matter is made of atoms, and so is not continuous; however, on length scales much greater than that of inter-atomic distances, such models are highly accurate. Fundamental physical laws such as the conservation of mass, the conservation of momentum, and the conservation of energy may be applied to such models to derive differential equations describing the behaviour of such objects, and some information about the particular material studied is added through constitutive relations.

Continuum Mechanics deals with physical properties of solids and fluids which are independent of any particular coordinate system in which they are observed. These physical properties are then represented by tensors, which are mathematical objects that have the required property of being independent of coordinate system. These tensors can be expressed in coordinate systems for computational convenience.

Definitions (#9.7.467):

D1. We name "medium", any fluid (solid, liquid, gas or plasma depending on what we have seen in the section of Thermodynamics), deformable or not, when we consider it a macroscopic point of view, as opposed to a corpuscular description.

D2. We name "continuous medium", a medium such that if M and M' belong to a medium and M' belongs to the neighbourhood of M, then whatever the deformation undergone by that environment, $\mathrm{d}M'$ will still belong to the neighbourhood of $\mathrm{d}M$.

This field is often seen as the engineering science for understanding and describing the material world around us and currents phenomena that take place: liquid movements, gas, flying airplanes, helicopters, rockets, satellites, sailing boats, solids deformations, internal structure of stars, etc. By its relations with thermal mechanics (thermodynamics), it extends to the thermal analysis, energy analysis, acoustic and even General Relativity (the Universe being considered as a continuum material on long distances)!

Taking into account the behaviour of continuum, it encompasses hydrodynamics, gas dynamics, elasticity, acoustics, plasticity and other behaviours. It is the key to what we now name "modelling", which is nothing but the art of analysing a physical phenomenon and describe it mathematically, allowing their study with rigour specific to this discipline.

This section of the book is divided into four main parts: solid, liquid, gas and plasma (some concepts have been deliberately developed in the section of Music Mathematics page 8195). In each part, we introduce the specific mathematical tools to study a particular continuum with a complexity (all relative) growing. However, by choice and as always in this textbook, it was decided to present the theorems with the simplest possible mathematical tools but all arriving at the same results. For example, the proof of the Navier-Stokes equation that would take 150 pages of rigorous mathematical developments do takes no more than 27. There is therefore a significant advantage both for the writer (...) and for the reader do so.

Remark

Regarding the Navier-Stokes, we also give practical closed-forms examples of these in our study of Meteorology (see section Marine & Weather Engineering page 8239) and when we will have time we will give an easy example of a liquid wave simulation in MATLAB® in the section of Theoretical Computing.

9.7.1 Rigid Bodies

Atoms of the same element or of different elements are assembled in specific structures. This conditions the strength of their electrical interactions, which define the final structure of the substance. Under normal conditions on our planet, matter exists in solid, liquid, gas or plasma. If the inter-atomic forces are sufficiently intense, the particle collection retains its shape and volume.

This property of retaining the shape and volume, as well as elastic properties distinguish solids from other states of matter.

9.7.1.1 Pressures

The concepts of "compression" and "constraint" (that we can include improperly into the global term "pressure") are of prime importance in Continuum Mechanics. It is therefore necessary to define the different types of pressure with a minimum of rigour!

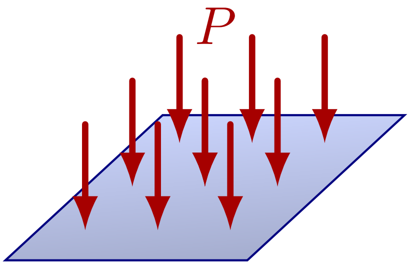
Definitions (#9.7.468):

D1. We name "compression pressure" traditionally denoted P, the ratio expressed by the force F which is exerted (applied) on a surface element S to the normal thereof. Thus, in scalar form:

$$\boxed{P=\frac{F}{S}} \tag{9.7.1}$$

definition that is valid only if This is incorrect if the force being applied is perpendicular to the surface.

Pressure in reality is there even if no surfaces or forces are present! In the middle of a gas bottle, gas has pressure. You can imagine putting a virtual surface there, and no matter how you orient it, you'd get the force of same magnitude, but that's just a side-effect.



Remark

If a force acts on a finished surface, then we also speak of "distributed force".

D2. We name "constraint pressure" the ratio expressed by the force F that pulls on a surface element S not necessarily perpendicularly, traction force which can then be divided into two respectively tangent and normal vectors. So as into vector form:

$$\boxed{\vec{\sigma}+\vec{\tau}=\frac{\mathrm{d}\vec{F}}{\mathrm{d}S}=\vec{T}} \tag{9.7.2}$$

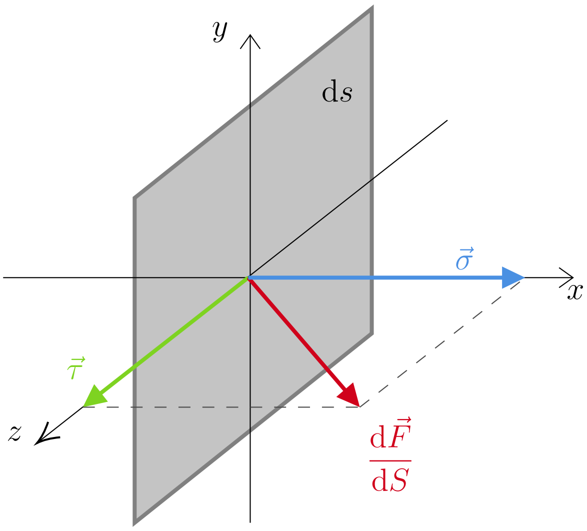


Figure 9.184: Illustration of normal and tangential constraints (stresses)

where $\vec{\sigma}$ and $\vec{\tau}$ are respectively the "normal constraint" and the "tangential constraint" (also sometimes denoted with an S as indices to indicates that this is relatively to a surface).

Both variables above are measured in $[\mathrm{N}\cdot\mathrm{m}^{-2}]$ or "Pascals [Pa]" and by definition (as already mentioned during our study of Units), $100,000$ [Pa] is equal 1 [bar].

Conversion factors for pressure measurement units							
	1MPa	1 at	1psi	1 Pascal	1 bar	1 atm	1 Torr
MPa $[\text{N/mm}^2]$	1	10.2	$145,038$	10^6	10	9.87	$7,500$
at $[\text{kg/cm}^2]$	0.0981	1	14.2	$98,100$	0.981	0.968	736
psi $[\text{lbf/in}^2]$	$6.89\cdot 10^{-3}$	$7.02\cdot 10^{-2}$	1	$6,890$	$6.89\cdot 10^{-2}$	$6.8\cdot 10^{-2}$	51.80
Pa $[\text{N/m}^2]$	10^{-6}	$1.02\cdot 10^{-5}$	$1.45\cdot 10^{-4}$	1	10^{-5}	$9.87\cdot 10^{-6}$	0.0075

atm [760 torr]	0,1013	1,0332	14,7	101325	1,013	1	760
torr	$1.33\cdot 10^{-4}$	$1.36\cdot 10^{-3}$	$1.93\cdot 10^{-2}$	133	0.00133	0.00132	1

Table 9.33: **Conversion factors for pressure measurement units**

Keep in mind that the standard atmosphere at the ground level has a pressure of $101,325\;[\text{N}\cdot\text{m}^{-2}]$ and in this early 121st century (according to holocene calendar) the most powerful industrial press belongs to GIVA's Forgiatura a Vienna facility in Italy, with an estimated mass equivalent of $100,000$ tons on a surface of maximum $90\;[\text{m}^2]$ hence a pressure of $\sim 10^7\;[\text{N}\cdot\text{m}^{-2}]$ (one hundred times the atmospheric pressure) or on a typical working surface of $1\;[\text{m}^2]$ this gives a pressure of $\sim 10^8\;[\text{N}\cdot\text{m}^{-2}]$ (one thousand times the atmospheric pressure):

Figure 9.185: **Hydraulic press owned by the GIVA's Forgiatura in Italy**

We could very well include the above two definitions in only one and work with the signs of the forces. But to be consistent with what is taught in schools, we will keep these two definitions that identify by definition the fact that the forces are opposed relative to a surface element S.

Remark

We will give the definition of hydrostatic pressure further below during our study of liquids.

Caution! A common mistake is to think that pressure is a vector... Indeed strictly speaking, the pressure p is proportionality factor defined by:

$$\vec{F}=p\vec{S}=p\vec{n}S \qquad (9.7.3)$$

where the surface $\vec{S}$ is the one that gives the direction. We have to recall that pressure is defined everywhere in the bulk volume, not just at the surface. A volume of gas has pressure defined everywhere. And the force direction is determined by us - by the way we orient your surface that you put into the gas.

Therefore it is incorrect (although rather usual) to say "*the pressure is directed in such or such direction*". The pressure, as a scalar, has no direction. The force given by the previous relationship to the quantity has a direction, but the pressure does not. If we change the orientation of the surface element, the direction of the normal force changes accordingly, but the pressure remains the same.

If $\vec{F}$ is just caused by the pressure, it can't be anything else but perpendicular to the area, otherwise you have other forces present in the system, or the liquid is not isotropic.

But as reality is always more complex than it seems, we will se later that in reality pressure is a tensor (the "Cauchy stress tensor" and then pressure is the average of the stress tensor over all orientations and in a fluid which isn't moving, this is the only stress that is allowed), but for gasses, it's isotropic, so it acts as a scalar.

9.7.1.2 Elasticity of Solids

In one way or another, a compressive or tension constraint can deform the triple: height, width, thickness of a body. Directly address to the study of a case that deform these three parameters is a bit long and will be discussed further below in the part on the determination of the expression of Young's shear modulus.

But it could be useful, at least only from the point of view of the vocabulary to give an example from the most simplistic case in can be. If we imagine a one dimension elastic body (having neither height nor width, but just a length) under the application of two perfectly collinear constraints but antagonists forces, we can imagine that the considerated body is lengthen from a given factor.

Definition (#9.7.469): The "normal deformation" under axial and antagonists forces is given by the ratio between the change in body length to its original length (i.e.: the relative elongation) such that:

$$\boxed{\varepsilon=\frac{|\Delta L|}{L_0}} \qquad (9.7.4)$$

This relation is an extremely simplified form of all kinds of deformations that may exist. Indeed, when we rigorously studies the deformation, we must take into account the accumulated distortions and then we speak of "true longitudinal deformation", or even of "longitudinal rational deformation", by the change in length such that:

$$\mathrm{d}\varepsilon=\frac{\mathrm{d}L}{L} \tag{9.7.5}$$

Therefore after integration:

$$\varepsilon=\int_{L_0}^{L}\frac{\mathrm{d}L}{L}=\ln(L)|_{L_0}^{L}=\ln\left(\frac{L}{L_0}\right) \tag{9.7.6}$$

We can consider in all generality that:

$$L=L_0+\Delta L \tag{9.7.7}$$

Therefore it comes (the same reasoning applying for a surface or a volume)

$$\varepsilon=\ln\left(\frac{L_0+\Delta L}{L_0}\right)=\ln\left(1+\frac{\Delta L}{L_0}\right) \tag{9.7.8}$$

But we see above a well-known expression of usual Taylor series (see section Sequences and Series page 1703) and then we can write for small deformations:

$$\varepsilon\cong\frac{\Delta L}{L_0} \tag{9.7.9}$$

and we fall back on our initial naive definition. We also see that this approximation is also equivalent to put from start that:

$$\mathrm{d}\varepsilon=\frac{\mathrm{d}L}{L}\cong\frac{\Delta L}{L_0} \tag{9.7.10}$$

which is a writing (approximation) that we will see again in the section of Thermodynamics in our determination of the liquid state equation but with the volume V instead of the length L.

There is necessarily a relation between compression and tensile forces and the variation in size of a body. This relation is dependent on the atomic structure of the material and should rigorously use quantum physics to be determined (we will omit this approach in the section of this textbook). We observe, however, depending on the materials various characteristics that interest a the highest point engineers:

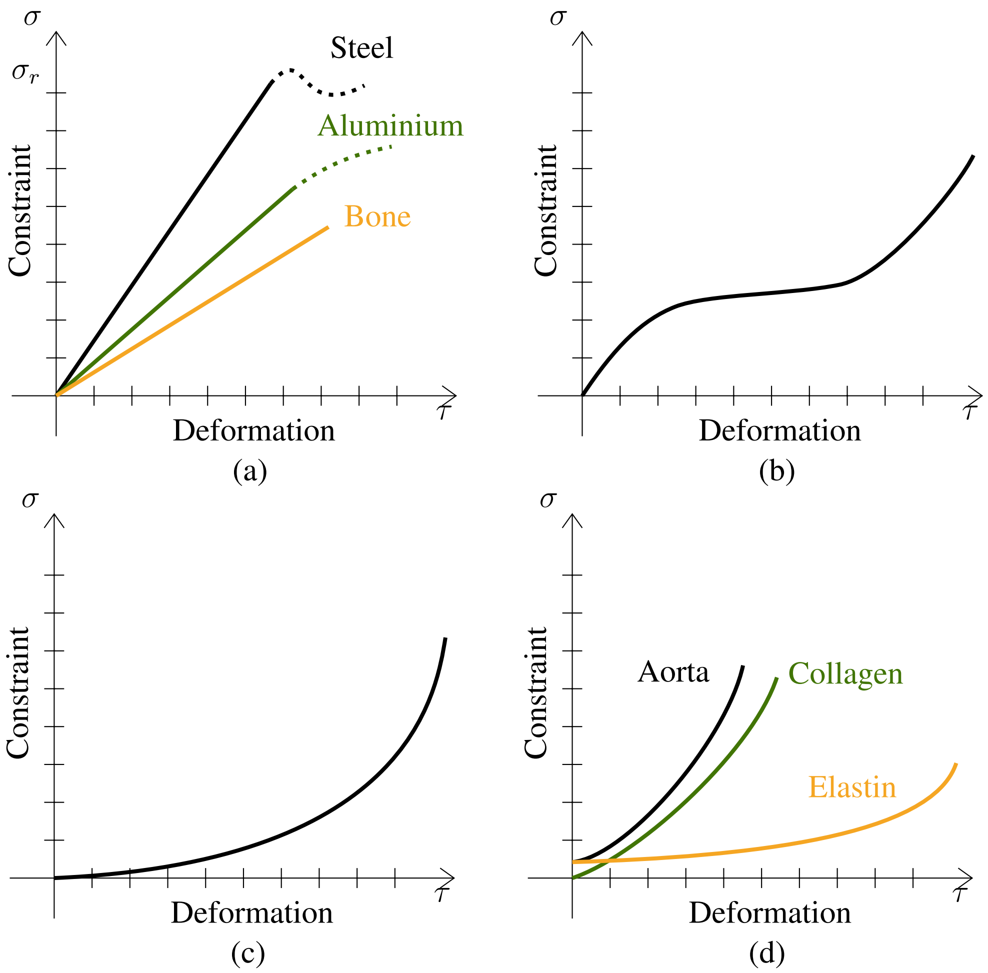

Figure 9.186: **Behaviour under stress/compression for some materials**

The above figures represent the variation of the compressive stress versus strain stress for some materials (typically we represent these characteristics by inverting the axes). We can observe that:

- Ductile materials such as mild steel (a) ceases to be linear in the elasticity limit denoted σ_r above.
- Under traction, rubber polymers (b) first lengthen their molecules and pulling their chemical bonds (see section Quantum Chemistry page 6190).
- Most organic materials (c) are under constraint, even when if they are not distorted. The skin, for example, is as a big rubber glove enveloping the body.
- Elastin (d) is usually enhanced with collagen in biological systems such as arteries. A tendon is primarily made of collagen.

In a more general case, the engineers used to define the points shown below in their material constraint:

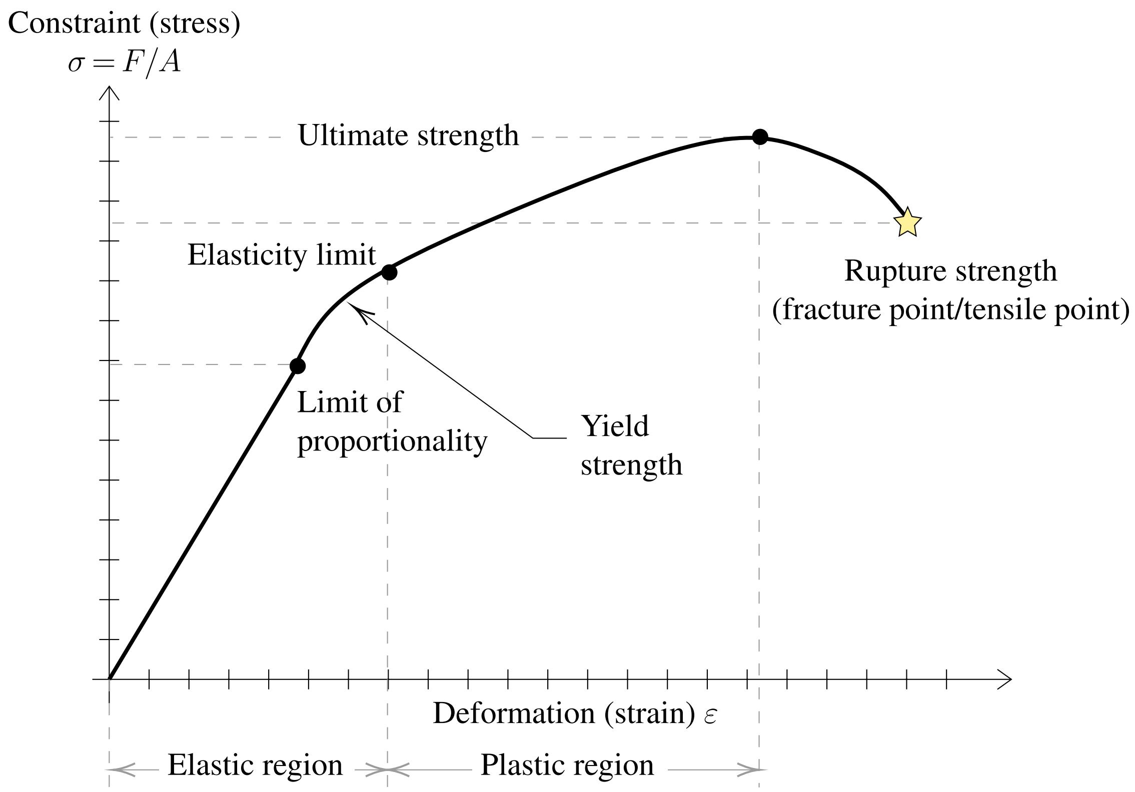

Figure 9.187: **Tensile Stress-Strain Diagram**

The above characteristic includes a linear portion as is the case of a certain class of materials. This means that the slope of the characteristic is a constant which reflects the elastic deformation of the material under the effect of increasing stress. This elastic stress by deformation unit defines the "Young's modulus" (there is no tangential component in this case study!):

$$\boxed{E = \frac{\sigma}{\varepsilon}} \tag{9.7.11}$$

also denoted sometimes by the letter Y to avoid obviously any confusion with energy. This relation is valid both compressive or in tension stresses. We will return to this relation in the following paragraphs.

Remarks

R1. "Rheology" is field of the mechanics that studies plasticity, elasticity, viscosity and the fluidity characteristics of the deformable body. This is a very important branch of industrial engineering.

R2. Be careful the calculations that will follow are relatively long and difficult, even if we tried to simplify them to the maximum as we always do in this textbook. However, all the results will be infinitely useful either to determine the Navier-Stokes equation or for the study of material strength (see section Mechanical Engineering page 8359)!

Definition (#9.7.470): The "toughness" is the ability of a material to absorb energy and plastically deform without fracturing. One definition of material toughness is the amount of energy per unit volume that a material can absorb before rupturing. It is also defined as a material's resistance to fracture when stressed.

Toughness can be determined by integrating the stress-strain curve as seen above. It is the energy of mechanical deformation per unit volume prior to fracture. The explicit mathematical description is:

$$\frac{\text{Energy}}{\text{Volume}}=\int_0^{\varepsilon_f}\sigma\mathrm{d}\varepsilon \tag{9.7.12}$$

where ε is strain, ε_f is the strain upon failure and σ is stress.

Typically in laboratories the toughness is multiplied by the length of the test specimen. This is why the toughness is given many times in Energy units by Surface units as in the figure below:

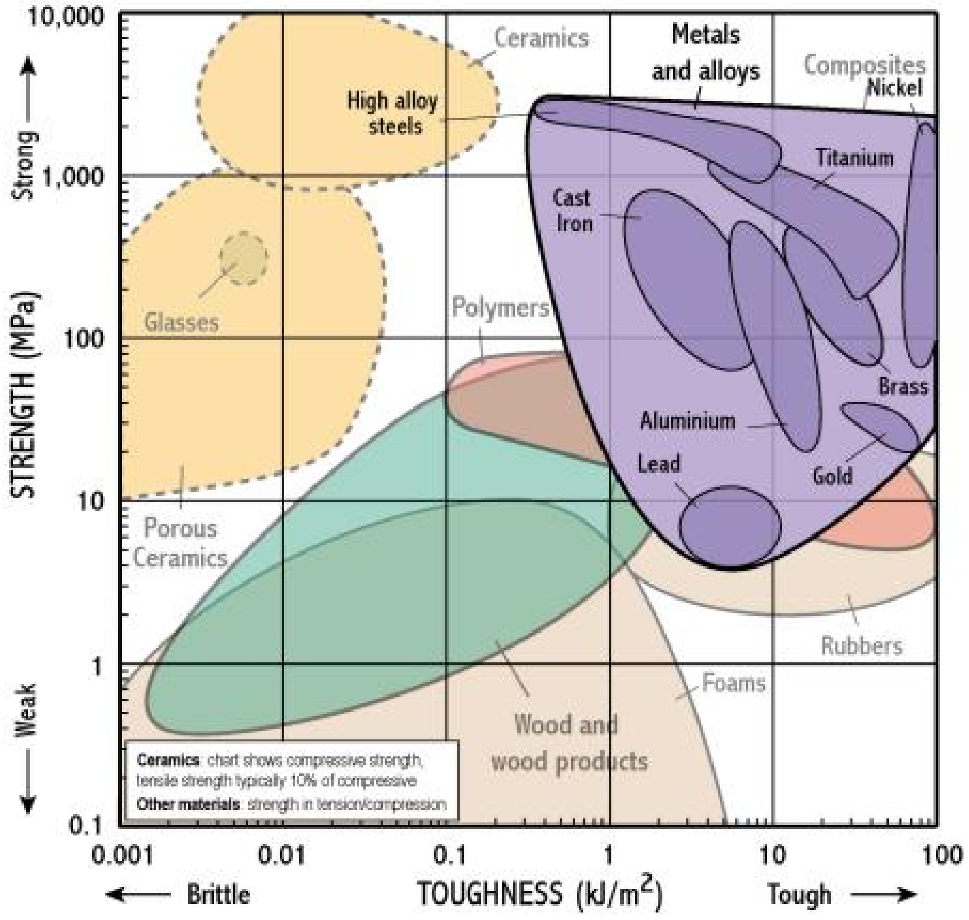

Figure 9.188: **Toughness schema of common material (source: ?)**

For example, brittle materials (like ceramics) that are strong but with limited ductility are not tough; conversely, very ductile materials with low strengths are also not tough. To be tough, a material should withstand both high stresses and high strains. Generally speaking, strength indicates how much force the material can support, while toughness indicates how much energy a material can absorb before rupturing.

For general knowledge here is a diagram of strength vs density for various materials (sadly the source in unknown):

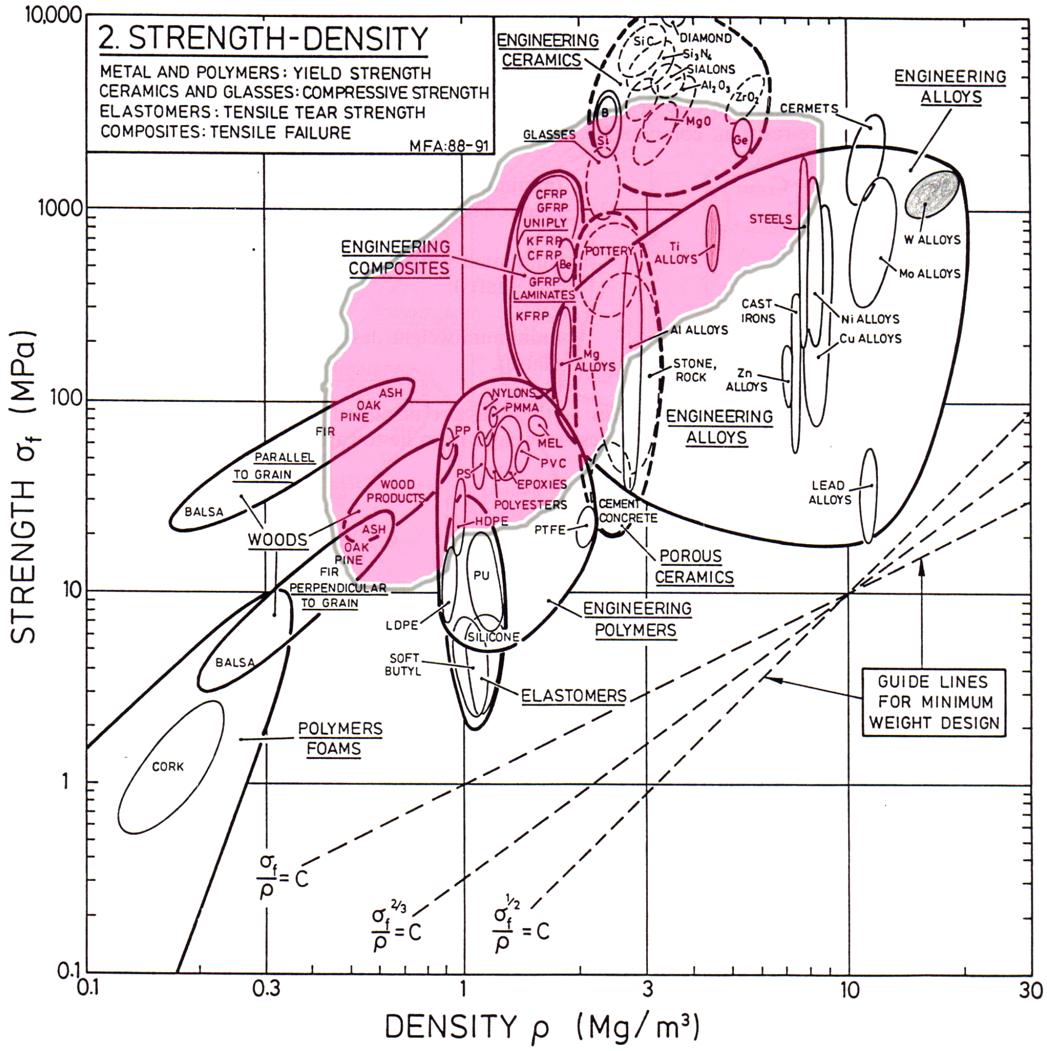

Figure 9.189: Strength vs Density of some materials (source: ?)

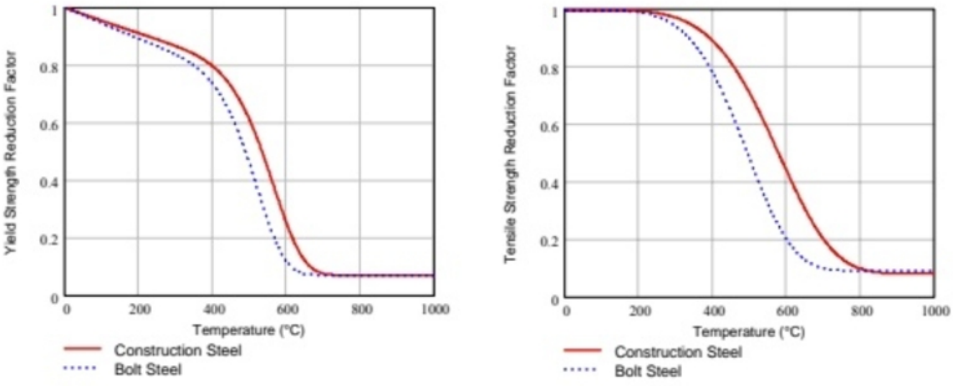
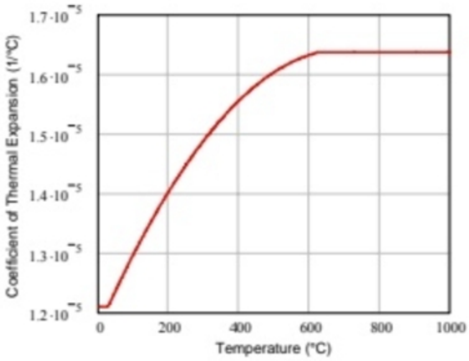
The reader must keep in mind that obviously, as always in physics, these properties are temperature dependant:



Yield strength reduction factor

Tensile strength reduction factor



Instantaneous coefficient of thermal expansion

Figure 9.190: **Variation of various steel strengths as function of temperature (source: NIST)**

9.7.1.2.1 Hooke's law

Hooke's law is a principle of physics that states that the force F needed to extend or compress a spring by some distance ΔL is proportional to that distance. An elastic body or material for which this assumption can be assumed is said to be "linear-elastic" or "Hookean".

On the other hand, Hooke's law is an accurate approximation for most solid bodies, as long as the forces and deformations are small enough. For this reason, Hooke's law is extensively used in all branches of science and engineering, and is the foundation of many disciplines such as seismology, molecular mechanics and acoustics. It is also the fundamental principle behind the spring scale, the manometer, and the balance wheel of the mechanical clock.

The modern theory of elasticity generalizes Hooke's law to say that the strain (deformation) of an elastic object or material is proportional to the stress applied to it.

Taking into consideration the definitions given above:

$$\sigma=\frac{F}{S} \qquad \varepsilon=\frac{|\Delta L|}{L_0} \qquad E=\frac{\sigma}{\varepsilon} \tag{9.7.13}$$

we get the relation:

$$\boxed{\frac{|\Delta L|}{L_0}=\frac{F}{ES}} \tag{9.7.14}$$

which by definition is the "linear Hooke's Law" in normal stress only!

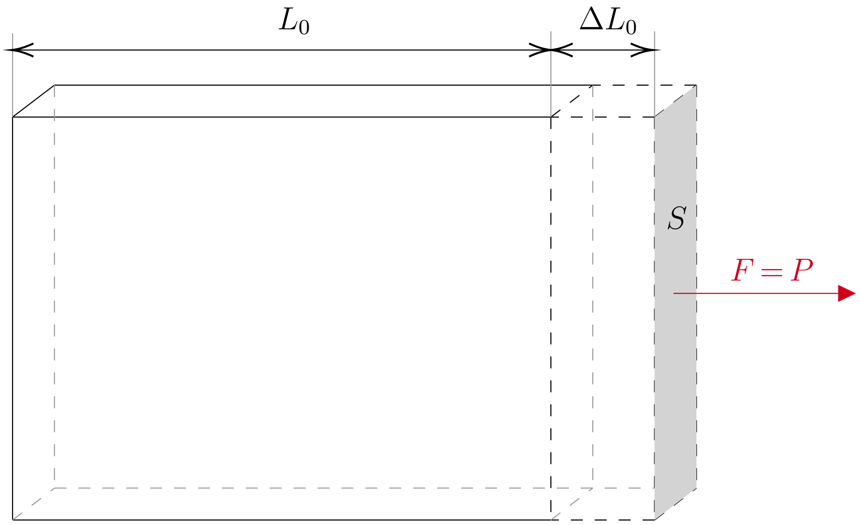


Figure 9.191: **Illustration of the effect of a normal stress**

✍**Example:**

Consider a suspension cable used to carry gondolas at ski resorts and that the cable has an unsupported span of 3 [km]. We assume that the cable has a radius of $r=2.3$ [cm] and its tension is $3.0\cdot 10^6$ [N]. The stretch of the steel cable is therefore equal to:

$$|\Delta L|=\frac{F}{ES}L_0=\frac{3\cdot 10^6}{210\cdot 10^9\cdot\pi(0.028)^2}\cdot 3000\cong 17.5\,[\text{m}] \tag{9.7.15}$$

It is quite intuitive to assume that the higher the bonding force of the atoms constituting the study material, the greater is the force to be applied to take them away, so to stretch the body. Solids, which have big bond strengths, have a high melting temperature (this is detailed in the section of Quantum Chemistry).

If we denote:

$$k:=\frac{ES}{L_0} \tag{9.7.16}$$

We end up with a relation that we already know:

$$\boxed{F=k|\Delta L|} \tag{9.7.17}$$

which is the restoring force of springs (see sections of Classical Mechanics page 3417 and Mechanical Engineering page 3416) and just a variant notation of Hooke's law.

There is also another way to introduced Hooke's law that is quite interesting and used in many other fields of physics (especially in Solid State Physics) as it used the microscopic picture of a solid.

Let us consider for this purpose a solid piece of some simple material. If we look at pure elemental solids – for example metals – we often find that when they form a solid the atoms arrange themselves into a regular lattice that is "close packed" – arranged so that the atoms more or less touch each other with a minimum of wasted volume. There are a number of kinds of lattices that appear (determined by the subtleties of the quantum mechanical interactions between the atoms) but in many cases the lattice is a variant of the cubic lattice where there are atoms on the corners of a regular cartesian grid in three dimensions (and sometimes additional atoms in the center of the cubes or on the faces of the cubes).

Not all materials are so regular. Materials made out of a mixture of atoms, out of molecules made of a mixture of atoms, out of a mixture of molecules, or even out of living cells made out of a mixture of molecules. The resulting materials can be ordered, structured (not exactly the same thing as ordered, especially in the case of solids formed by life processes such as bone or coral), or disordered (amorphous).

As usual, we will deal with all of this complexity by ignoring most of it for now and considering an "ideal" case where a single kind of atoms lined up in a regular simple cubic lattice is sufficient to help us understand properties that will hold, with different values of course, even for amorphous or structured solids.

This is illustrated in the figure below:

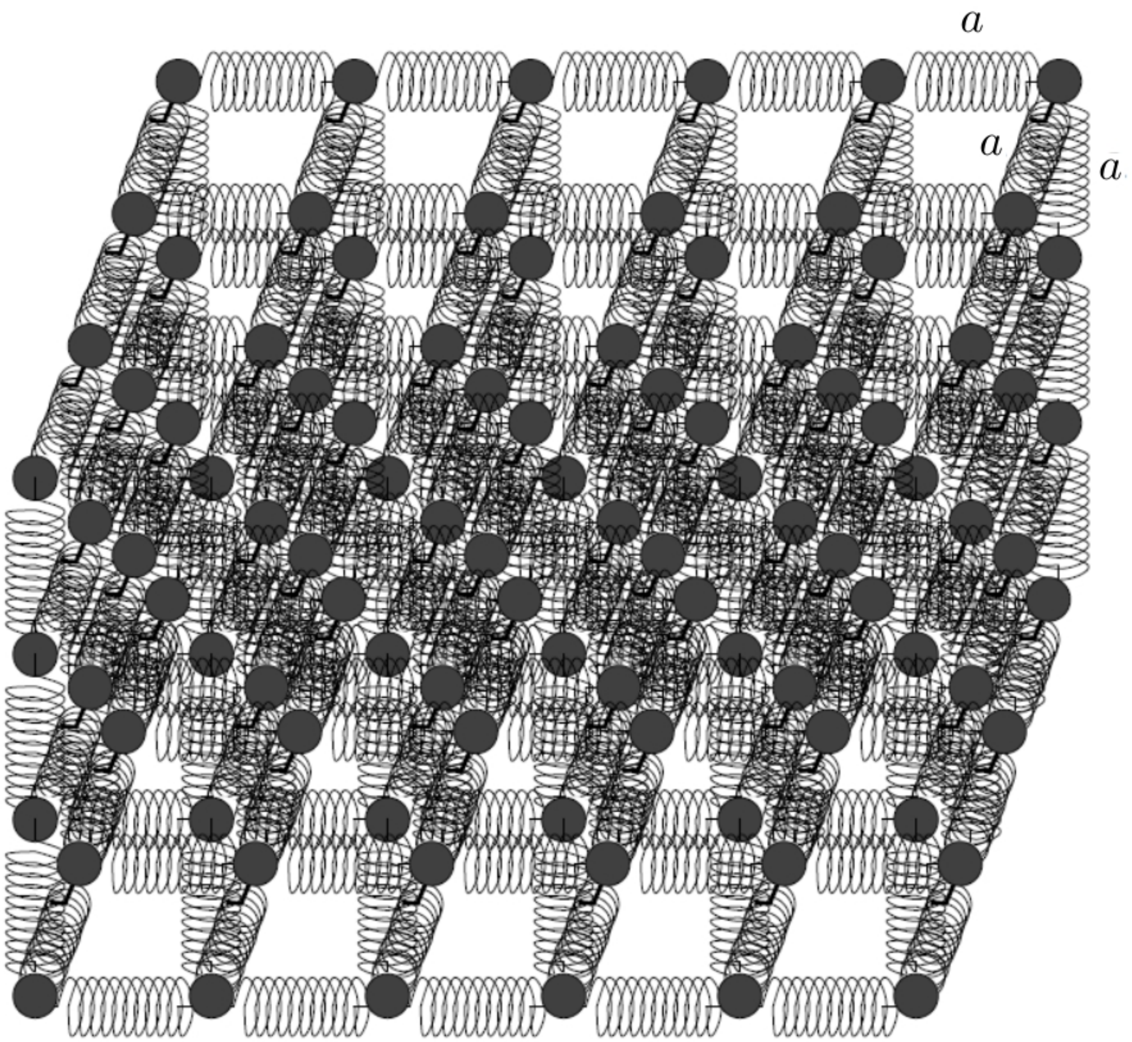

Figure 9.192: Idealized simple cubic lattice of atoms separated by the "springs" of inter-atomic forces that hold them in equilibrium positions

which is basically a mental cartoon model for a generic solid – lots of atoms in a regular cubic lattice with a cube side a, where the inter-atomic forces that hold each atom in position is represented by a spring, a concept that is valid as long as we don't compress or stretch these inter-atomic bonds by too much.

We need to quantify the numbers of atoms and bonds in a way that helps us understand how stretching or compressing forces are distributed among all of the bonds. Suppose we have N_x atoms in the x-direction, so that the length of the solid is $L = N_x a$. Suppose also that we have N_y and N_z atoms in the y- and z-directions respectively, so that the cross-sectional surface is therefore:

$$S = N_y N_z a^2 \tag{9.7.18}$$

Now let us imagine applying a force (magnitude F) uniformly to all of the atoms on the left and right ends (see figure below) that stretches all of these bonds by a small amount Δx, presumed to be "small" in precisely the sense that leaves the inter-atomic bonds still behaving like springs. The force F has to be distributed equally among all of the atoms on the end areas on both sides, so that the force applied to each chain of atoms in the x-direction end to end is:

$$F_{\text{chain}} = \frac{F}{N_y N_z} = \frac{F}{\dfrac{S}{a^2}} = \frac{Fa^2}{S} \tag{9.7.19}$$

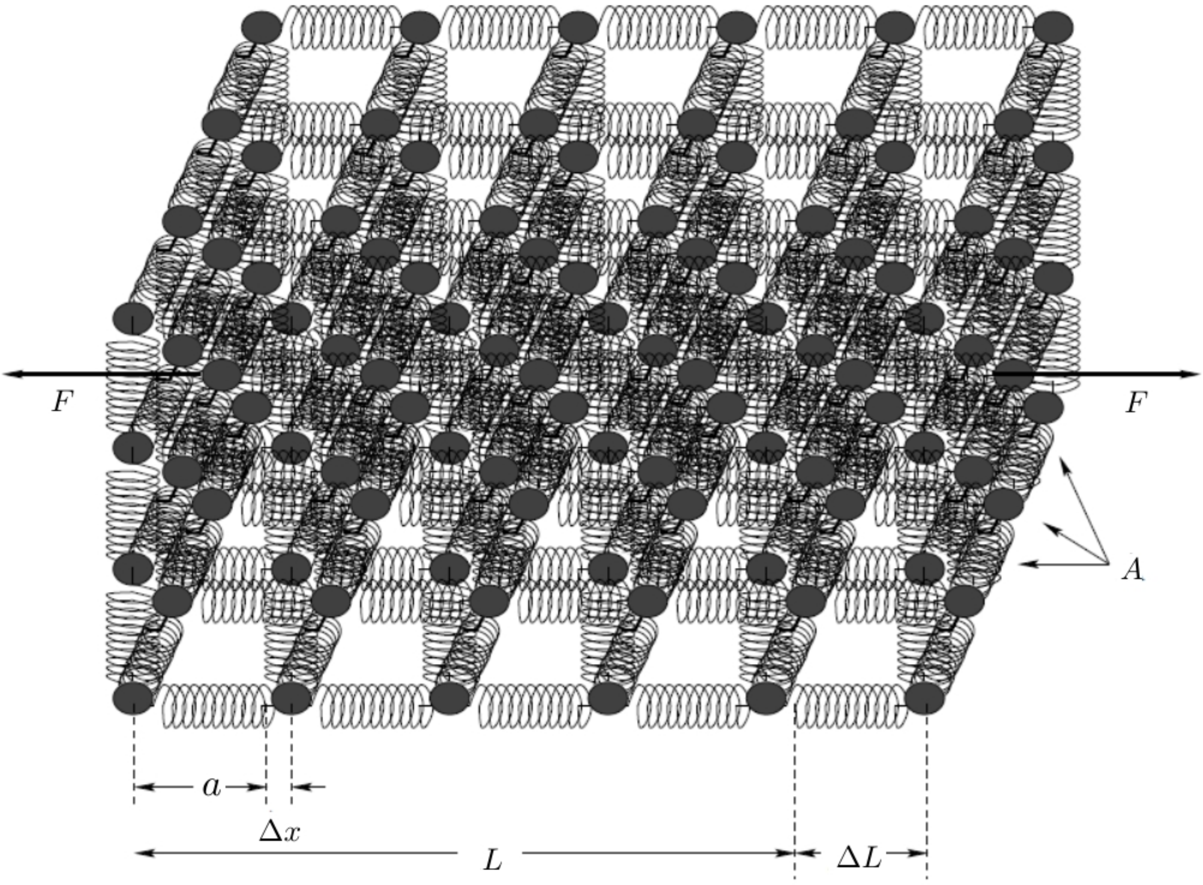

Figure 9.193: The same lattice stretched by an amount ΔL as a force F is applied to both ends, spread out uniformly across the cross-sectional area of the faces A.

Each spring in the chain is stretched by this force between the atoms on the ends, so that:

$$F_{\text{chain}}=-\frac{Fa^2}{S}=-K\Delta x \tag{9.7.20}$$

The negative sign just means that the springs are trying to go back to their equilibrium length and hence oppose the applied force. We multiply this by 1 in the form $(aN_x)/(aN_x)$ to get:

$$\frac{Fa^2}{S}=-K\frac{aN_x}{aN_x}\Delta x \tag{9.7.21}$$

giving as$L=aN_x$:

$$\frac{Fa^2}{S}=-Ka\frac{N_x\Delta x}{L}=-Ka\frac{\Delta L}{L} \tag{9.7.22}$$

Finally, we rearrange this by putting all of the extra terms together as follows (we see that we fall back on Hooke's law):

$$\frac{F}{S}=-\frac{K}{a}\frac{\Delta L}{L}=-E\frac{\Delta L}{L} \tag{9.7.23}$$

In words, we define $\sigma=F/S$ to be the "Stress", $\varepsilon=\Delta L/L$ to be the "Strain", and $E=K/a$ to be Young's Modulus. With these definitions, the equation above states that: Compressive or extensive Stress applied to a solid equals Young's Modulus times the Strain.

But there are several types of constraints with their respective modules. So here are the most important definitions in the linear part of their characteristic associated with the explanatory diagram:

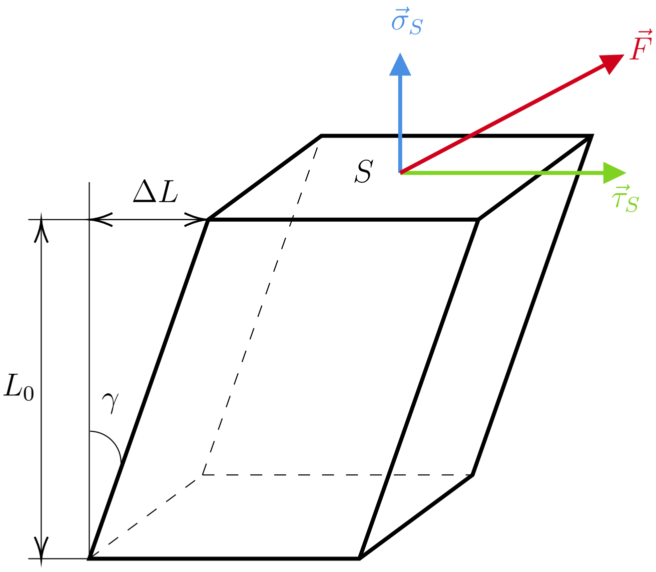

Figure 9.194: **Illustration of the effect of a shear stress**

Definitions (#9.7.471):

D1. We define the "shear modulus" or "rigidity modulus" by the ratio of the normal component of the force (compression pressure) to the shear strain:

$$G=\frac{\sigma_S}{\varepsilon_S}=\frac{F_N/S}{\gamma} \tag{9.7.24}$$

where the numerator is named the "shear stress" and where γ is the "angle of deformation". Generally this angle being small, we have the approximation:

$$\varepsilon_S = \gamma \cong \tan(\gamma) = \frac{|\Delta L|}{L_0} \tag{9.7.25}$$

S is the surface of the upper or lower face of the deformed body shown in the figure above.

D2. We define the "sliding elastic modulus", also named "sliding modulus" and most commonly "shear modulus" or "Coulomb modulus" by the ratio of the tangential component of the force (shear stress) to the shear strain:

$$G = \frac{\tau_S}{\varepsilon_S} = \frac{F_T/S}{\gamma} = \frac{E}{2(1+\eta)} \tag{9.7.26}$$

where η is the "Poisson's coefficient" which we will prove later in detail where it comes from.

Notice well that even if the numerator of the above definition is a force divided by an area, this is not a pressure because the force is tangential to the surface (hence the T in index of F).

This is because any force can be decomposed into a normal and tangential force (see the above definition of the compression pressure and constraint pressure) that we have two distinct definitions above. In the vast majority of laboratories situations, we arrange to have a purely tangential force (again... hence the T in index of the F) or purely normal force (hence the N in index of the F) to the surface S.

In practice many times make usage of only the second definition and thus to such a level that the latter is often just named "rigidity modulus" also...

✍**Example:**

A very interesting thing (for the parenthesis ...) if we consider that the tectonic plates are in a shearing situation between themselves we then have according to the sliding modulus:

$$F_T = \gamma G S = \frac{|\Delta L|}{L_0} G S \tag{9.7.27}$$

But for a tectonic plate inf friction of length L_0 over a height H:

$$F_T = \frac{|\Delta L|}{L_0} G(L_0 H) = G\left(\frac{|\Delta L|}{L_0}\right)(L_0 H) \tag{9.7.28}$$

and since energy is a force multiplied by a distance, we get:

$$E = F_T \Delta L = \left[G\frac{|\Delta L|}{L_0}(L_0 H)\right]\Delta L = G\Delta L^2 H \tag{9.7.29}$$

which is typically the energy liberated by the shear of the friction of two tectonic plates whose contact surfaces have an average height H, an initial length L_0 and undergoing a deformation ΔL.

Typically for an earthquake of the type of Sumatra in the year 12009 according to holocene calendar (9.1 to 9.3 on Richter scale, 28 [km] underground, 200,000 deaths), we had:

$$\Delta L \cong 10\,[\text{m}] \quad H \cong 10,000\,[\text{m}] \quad L_0 \cong 10,000\,[\text{m}] \quad G \cong 10^{10}\,[\text{Pa}] \tag{9.7.30}$$

Therefore it comes:

$$E \cong 10^{16}\,[\text{J}] \tag{9.7.31}$$

in other words ... a thousand times the energy of the Hiroshima nuclear bomb in.

If we denote by M the empirical definition of magnitude of the Richter's scale magnitude, we get:

$$E \cong 10^{5+1.44M} = 10^{16} \Rightarrow M \cong 7.6 \tag{9.7.32}$$

while estimations give a range of 6.2 to 9.2 ... so we are not too bad in the theoretical approach.

D3. We define the "omnidirectional modulus", as the ratio of the volume constraint named "bulk stress" on the volumetric strain named "bulk strain" (we will prove further below the mathematical developments that lead to the last term of this relation):

$$\kappa = \frac{\varepsilon_v}{\sigma} = \frac{F/S}{\Delta V/V_0} = \frac{P}{\Delta V/V_0} = \frac{3(1-2\eta)}{E} \tag{9.7.33}$$

In practice it is much more interesting to use:

$$\Delta V = \frac{PV_0}{\kappa} \tag{9.7.34}$$

and to seek what material (depending on the context) maximize or minimize ΔV.

We could define many other modules such as the bending modulus, the pure bending modulus, the composed bending modulus, the twisting modulus... We will study some of them further below.

For each of the different definitions of modules that we can imagine, we can define a Hooke's law that is suitable to it. However, all this may seem rather arbitrary, but in fact it is not! Because all definitions of modules that we saw earlier are a special case of a generalized mathematical relation we will be prove in this textbook in a near future.

9.7.1.2.2 Shear Modulus

The necessary condition for a rigid solid to be in static equilibrium as we saw it in the section of Classical Mechanics, is that the resultant forces that are applied to the body is equal zero:

$$\vec{F}_{\text{ext}} = \vec{0} \tag{9.7.35}$$

However, when a solid is subjected to stresses and it can tolerate them, there can be a deformation which may be followed by a breaking or a similar modification. More precisely, there is "deformation" of a body (not necessarily solid) when the distance between the elements it is made of have changed.

When in the theoretical study of elasticity, we exclude modifications of the body studied such as breaks, we say that we restrict ourselves to the "elastic deformations".

The geometry and the physics of deformations can be complex. Their description is derived from that of a number of elementary deformations we will specify further the characteristics.

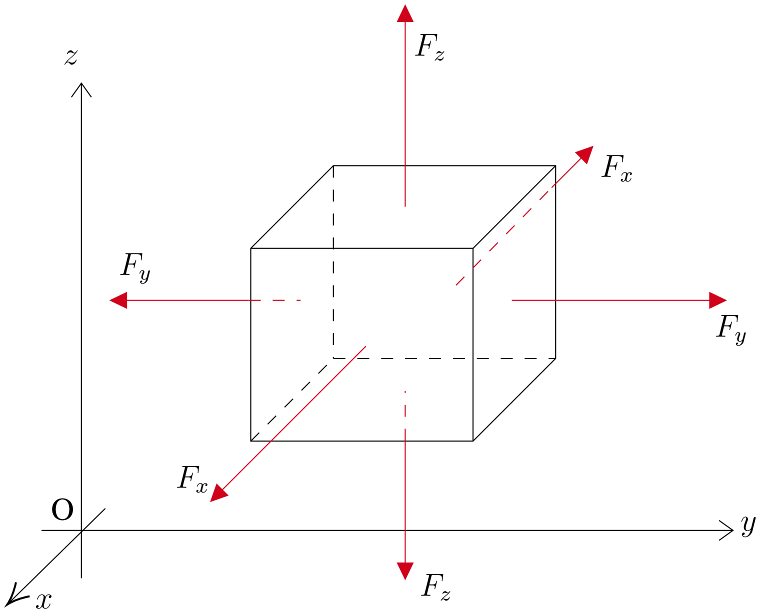

Figure 9.195: **Cube under normflexural modulusal stresses**

The scalar tensile stresses forces F_x, F_y, F_z generate on their faces "normal" tensions (that is to say perpendicular... for recall...):

$$\sigma_x = \frac{F_x}{S_x} \qquad \sigma_y = \frac{F_y}{S_y} \qquad \sigma_z = \frac{F_z}{S_z} \tag{9.7.36}$$

Assuming the only the force F_x acts, the unit deformation is by definition:

$$\varepsilon'_x = \frac{\sigma_x}{E} \tag{9.7.37}$$

When a parallelepiped is subjected to a tensile stress F_y, there is intuitively contraction of dimensions along the x direction. Contraction also observable also intuitively for F_z.

We then have if only the force F_y acts:

$$\varepsilon''_x = -\eta\frac{\sigma_y}{E} \tag{9.7.38}$$

where the sign "$-$" indicates a contraction and where η is a coefficient named "Poisson's coefficient".

If the Poisson coefficient of the studied matter is almost zero, this means that when you "crush" (compress) the material, its height decreases, but its width remains almost constant ...

One remark on the way: There are products that have a negative Poisson coefficient: when compressed, their width decreases! In general, it is porous media, inverted honeycomb style like expanded graphite that has this original property.

If only the force F_z acts:

$$\varepsilon'''_x = -\eta\frac{\sigma_z}{E} \tag{9.7.39}$$

By accepting the principle of superposition of forces, the effect of several forces acting simultaneously is equal to the sum of the effects produced by each of the superimposed forces acting separately (this is obviously a strong assumption!). Since then:

$$\varepsilon_x = \varepsilon'_x + \varepsilon''_x + \varepsilon'''_x \tag{9.7.40}$$

This can be considered as acceptable, given the linearity of the equations linking the unit deformation and the normal stresses. We then get:

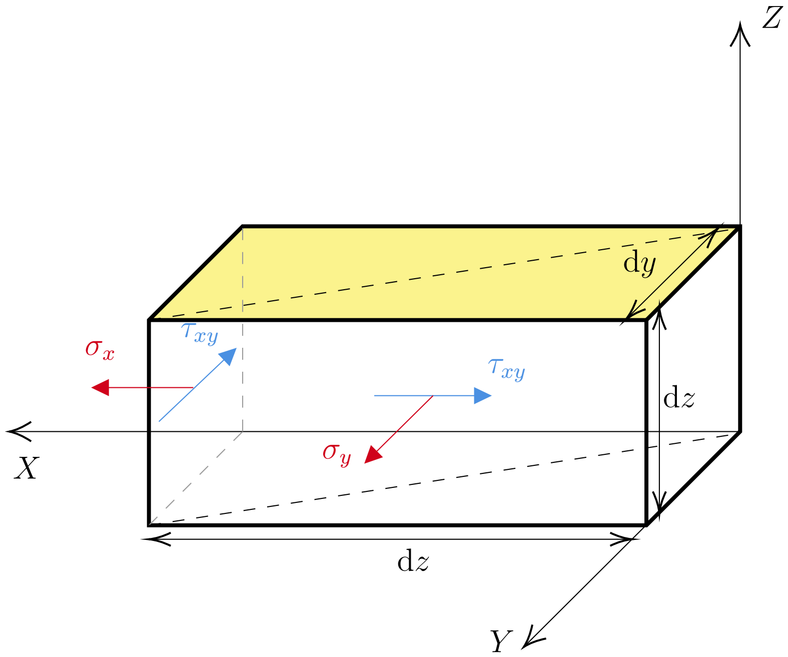
$$\begin{aligned}\varepsilon_x &= \frac{1}{E}\left[\sigma_x - \eta(\sigma_y + \sigma_z)\right]\\ \varepsilon_y &= \frac{1}{E}\left[\sigma_y - \eta(\sigma_x + \sigma_z)\right]\\ \varepsilon_z &= \frac{1}{E}\left[\sigma_z - \eta(\sigma_x + \sigma_y)\right]\end{aligned} \tag{9.7.41}$$

having proceed in the same way for the other two directions following the y-axis and z-axis.

From the previous relations, it is easy to find the equations linking σ to ε by solving the following linear system (see section Linear Algebra page 1929):

$$\begin{aligned}\sigma_x &= \frac{E}{1+\eta}\left[\varepsilon_x + \frac{\eta}{1-2\eta}(\varepsilon_x + \varepsilon_y + \varepsilon_z)\right]\\ \sigma_y &= \frac{E}{1+\eta}\left[\varepsilon_y + \frac{\eta}{1-2\eta}(\varepsilon_x + \varepsilon_y + \varepsilon_z)\right]\\ \sigma_z &= \frac{E}{1+\eta}\left[\varepsilon_z + \frac{\eta}{1-2\eta}(\varepsilon_x + \varepsilon_y + \varepsilon_z)\right]\end{aligned} \tag{9.7.42}$$

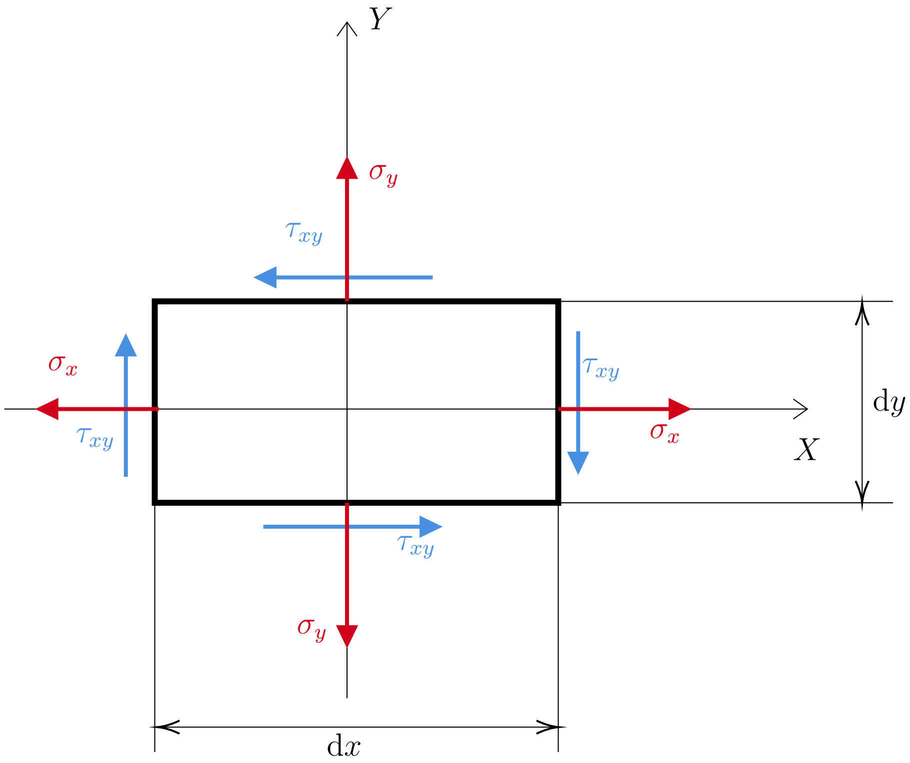
Given a material subject to various constraints. Inside of it, we operate in thought, to the extraction of a rectangular parallelepiped:



Z
dy
τ_{xy}
σ_x
τ_{xy}
dz
X
σ_y
dz
Y

Figure 9.196: **Parallelepiped rectangle p for the theoretical study**

The surfaces thereof are solicited by normal σ and tangential τ stresses (in the figure below the solid is in static equilibrium). Here is the yellow face:



Y
σ_y
τ_{xy}
σ_x
τ_{xy}
τ_{xy}
σ_x
X
dy
τ_{xy}
σ_y
dx

Figure 9.197: **Generic illustration of a material under normal and tangential stresses**

The normal σ and tangential τ constraints represent the actions of the parallelepiped material extracted mentally on the faces of the examined item.

It is interesting (in the sense that it facilitates the analysis) to seek the constraints that exist in a plane making an angle θ with the x-axis. To do this, we imagine a material triangle having a top angle θ extracted from matter mentally. We neglect the influence of gravity.

Therefore:

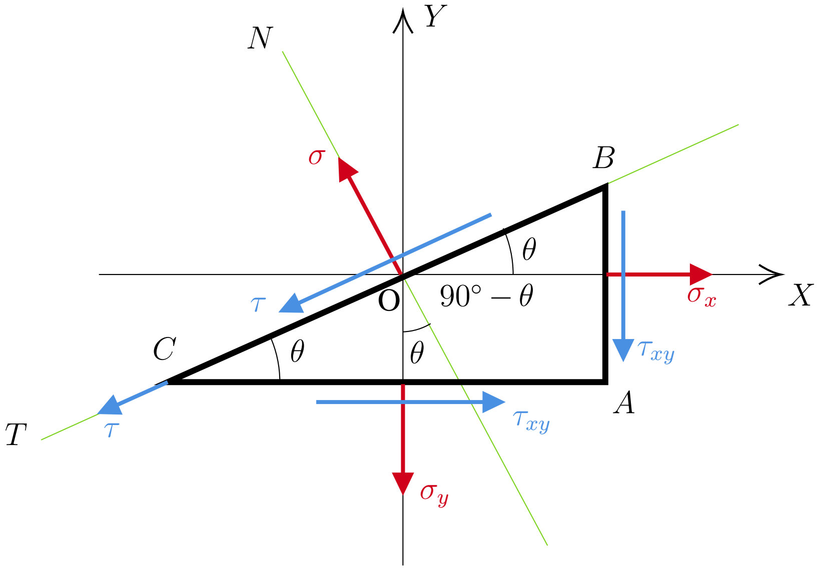


Figure 9.198: Search of constraints expressions in an oblique plane

Let us put:

$$\overline{CB} = \mathrm{d}s \qquad \overline{CA} = \mathrm{d}x \qquad \overline{AB} = \mathrm{d}y \tag{9.7.43}$$

and $\mathrm{d}z$ being the thickness of the solid (not shown in the diagram above).

On the length $\mathrm{d}s$ constraints appear and are decomposed under normal σ and tangential τ stresses (the latter being also named "shear stress" or "bending stress" as we already know).

The problem is to establish the relations between σ, τ and σ_x, σ_y and τ.

The sign conventions are:

- The constraints σ applying a traction are positive while the constraints σ exerting compression are negative.
- Constraints τ that tends to rotate the cuboid in the clockwise direction are positive. Counter-clockwise, they will be negative.

The projection equation of equilibrium following the direction ON is then:

$$\sigma_z \mathrm{d}z\mathrm{d}s - \left[\sigma_y \mathrm{d}z\mathrm{d}x\cos(\theta) + \sigma_x \mathrm{d}z\mathrm{d}y\cos\left(\frac{\pi}{2}-\theta\right) + \tau_{xy}\mathrm{d}x\mathrm{d}y\cos(\theta) + \tau_{xy}\mathrm{d}z\mathrm{d}x\cos\left(\frac{\pi}{2}-\theta\right)\right] = 0 \tag{9.7.44}$$

Let us recall that:

$$\sigma_i = \frac{F_{iN}}{S} \Leftrightarrow F_{iN} = S\sigma_i \tag{9.7.45}$$

As $\mathrm{d}x=\mathrm{d}s\cos(\theta)$ and $\mathrm{d}y=\mathrm{d}s\sin(\theta)$ we have:

$$\begin{aligned}&\sigma\mathrm{d}s=\sigma_x\mathrm{d}s\sin^2(\theta)+\sigma_y\mathrm{d}s\cos^2(\theta)+\tau_{xy}\mathrm{d}s\sin(\theta)\cos(\theta)+\tau_{xy}\mathrm{d}s\sin(\theta)\cos(\theta)\\&\sigma=\sigma_x\sin^2(\theta)+\sigma_y\cos^2(\theta)+\tau_{xy}\sin(2\theta)\end{aligned}\tag{9.7.46}$$

As:

$$\sin^2(\theta)=\frac{1-\cos(2\theta)}{2}\quad\text{and}\quad\cos^2(\theta)=\frac{1+\cos(2\theta)}{2}\tag{9.7.47}$$

then:

$$\sigma=\frac{\sigma_x}{2}(1-\cos(2\theta))+\frac{\sigma_y}{2}(1+\cos(2\theta))+\tau_{xy}\sin(2\theta)\tag{9.7.48}$$

Finally:

$$\sigma=\frac{1}{2}(\sigma_x+\sigma_y)-\frac{1}{2}(\sigma_x-\sigma_y)\cos(2\theta)+\tau_{xy}\sin(2\theta)\tag{9.7.49}$$

As conclusion we can say that in function of σ_x, σ_y and τ_{xy}, it is possible to calculate the normal stress that exists on a plane surface of angle θ.

The projection equation of equilibrium is following the direction OT is:

$$\begin{aligned}&\tau\mathrm{d}z\mathrm{d}s-\sigma_x\mathrm{d}z\mathrm{d}y\cos(\theta)+\tau_{xy}\mathrm{d}z\mathrm{d}y\cos\left(\frac{\pi}{2}-\theta\right)+\sigma_y\mathrm{d}z\mathrm{d}x\mathrm{d}x\cos\left(\frac{\pi}{2}-\theta\right)-\tau_{xy}\mathrm{d}z\mathrm{d}x\cos(\theta)=0\\&\tau\mathrm{d}s=\sigma_x\mathrm{d}\sin(\theta)\cos(\theta)-\sigma_y\mathrm{d}s\sin(\theta)\cos(\theta)-\tau_{xy}\mathrm{d}s\sin^2(\theta)+\tau_{xy}\mathrm{d}s\cos^2(\theta)=0\\&\tau=\frac{1}{2}(\sigma_x-\sigma_y)\sin(2\theta)+\tau_{xy}(\cos^2(\theta)-\sin^2(\theta))\end{aligned}\tag{9.7.50}$$

as $\cos^2(\theta)-\sin^2(\theta)=\cos(2\theta)$ then finally:

$$\tau=\frac{1}{2}(\sigma_x-\sigma_y)\sin(2\theta)+\tau_{xy}\cos(2\theta)\tag{9.7.51}$$

The conclusion is that in function of σ_x, σ_y and τ_{xy} it is possible to calculate the tangential stress τ that exists on a plane surface of angle θ.

So finally with to both relations:

$$\begin{aligned}\sigma&=\frac{1}{2}(\sigma_x+\sigma_y)-\frac{1}{2}(\sigma_x-\sigma_y)\cos(2\theta)+\tau_{xy}\sin(2\theta)\\\tau&=\frac{1}{2}(\sigma_x-\sigma_y)\sin(2\theta)+\tau_{xy}\cos(2\theta)\end{aligned}\tag{9.7.52}$$

gives the values of the normal and tangential stresses in any cut in function of the normal and tangential stresses to the primitives axes.

Given now the following situation:

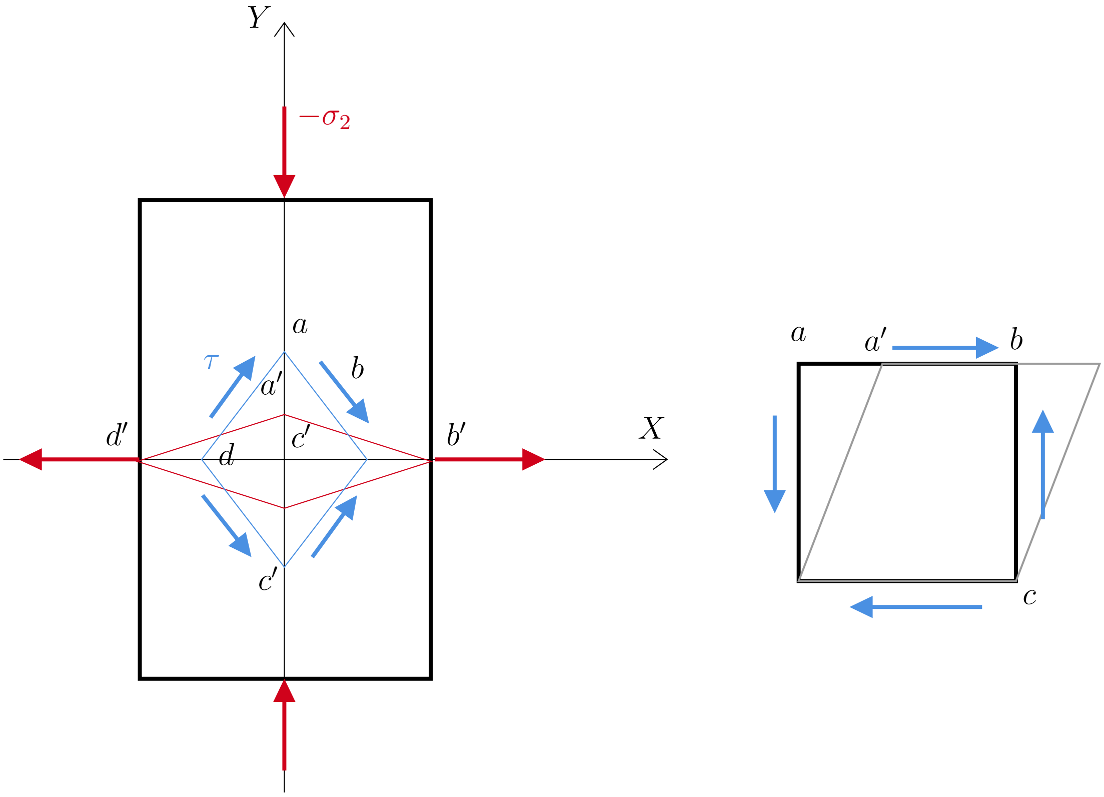

Figure 9.199: Situation for coming back to the study of the three dimensional case

On the figure above on the left the reader must imagine a block of material from which is virtually extracted a small square plane (in blue on the left figure) from which we will study in a first time only of the right triangles that compose it for afterwards study the whole.

Before solicitation, we therefore consider the diamond $abcd$ that is in fact originally a square with an angle of $\pi/4$ in the x direction. On the request of a reader here is perspective diagram of this situation:

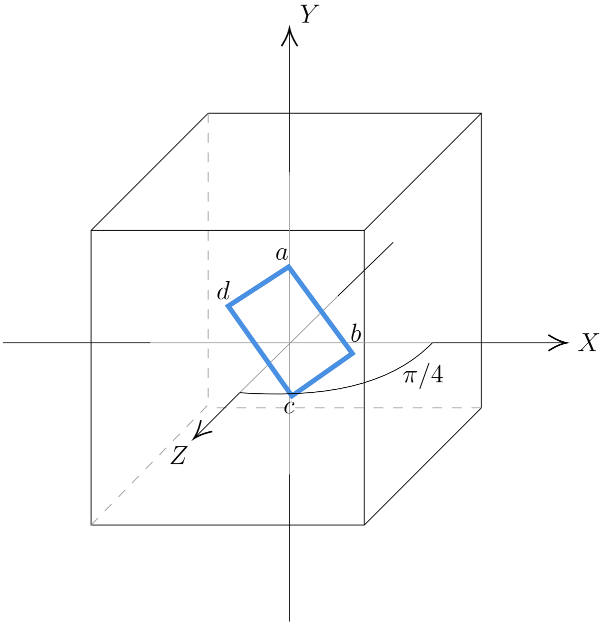

Figure 9.200: **Initial material block situation**

During solicitation, this diamond $abcd$ is deformed under the action of tangential stresses decomposed in pure shear stresses and becomes the diamond $a'b'c'd'$. Here is also a schema of this situation as requested by a reader:

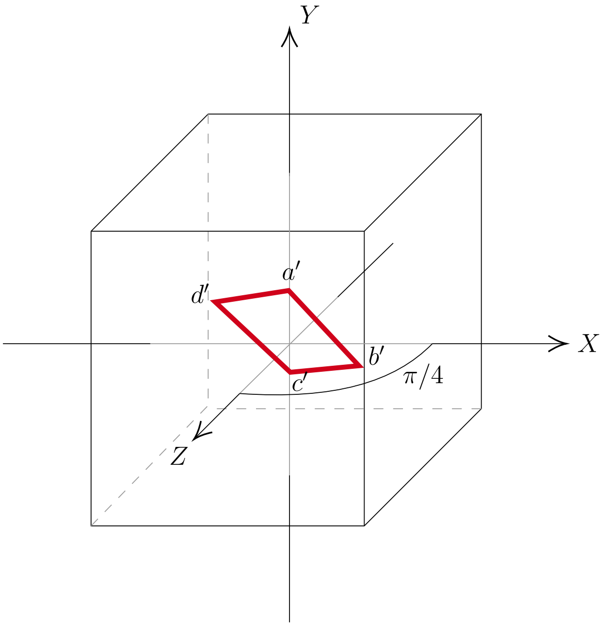

Figure 9.201: **Final material block situation**

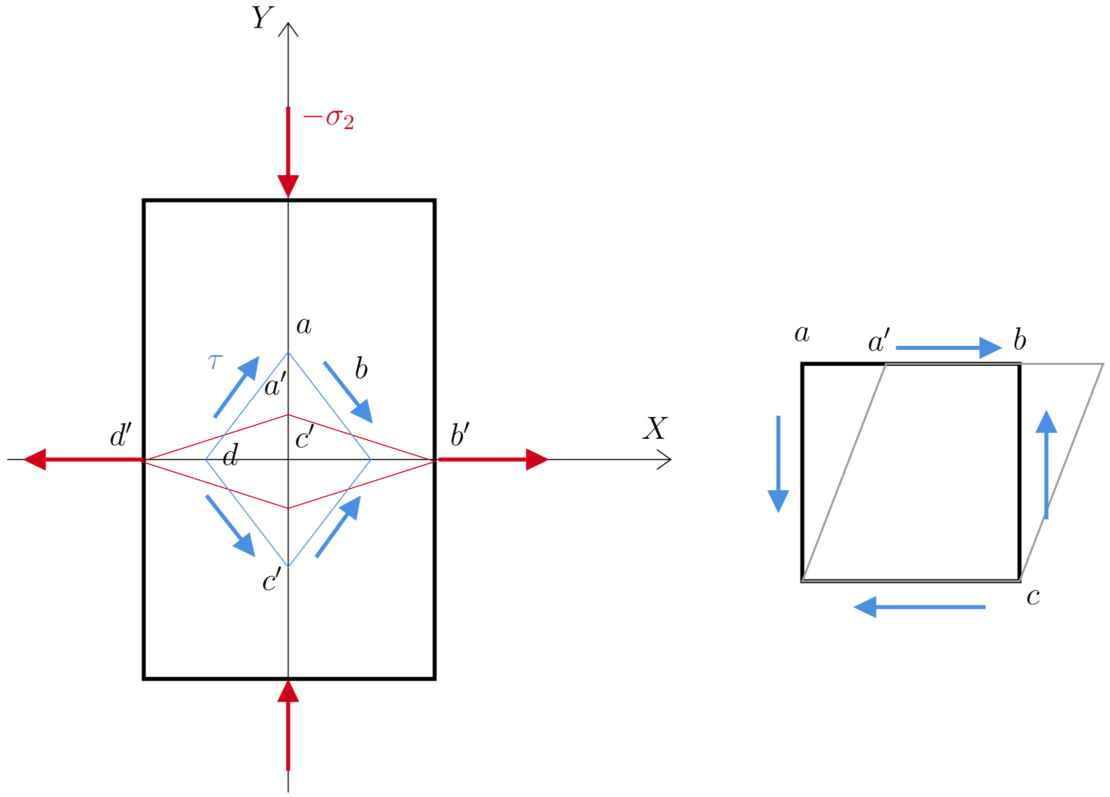
The diagonal $\overline{bd}$ is then extended and the diagonal $\overline{ac}$ is compressed. The angle $\hat{a}$ that had for value $\pi/2$ is after deformation equal to $\pi/2+\gamma$ (in a'). Similarly, the angle b which value was $\pi/2$ is after deformation equal to $\pi/2-\gamma$.

Remark

The angle γ is named "slip angle" and we consider it to be small.

We need only to look at the effect of the deformation by isolating the diamond and by applying on it a rotation of $\pi/4$. After deformation, we have the shape indicated by the red lines in the left part of the figure below (figure that we already know):



The slip angle being small, we have:

$$\frac{\overline{aa'}}{\overline{ad}}=\tan(\gamma)\cong\gamma \quad (9.7.53)$$

Therefore γ represents the slip of the side ab with respect to dc divided by the distance between the two planes ab and dc. The analysis that has been done is still valid whatever the solid or liquid body considered.

Given, now, the case of an elastic solid obeying Hooke's law. The problem will be to establish the relation between the slip angle γ and the tangential constraints τ acting on the sides of the diamond.

Given the right triangle Oab. The lengthening of the side $\overline{\text{O}b}$ and shortening of side $\overline{\text{O}a}$ during the deformation are obtained from the following equations:

$$\begin{aligned}\varepsilon_x&=\frac{1}{E}\left[\sigma_x-\eta(\sigma_y+\sigma_z)\right]\\ \varepsilon_y&=\frac{1}{E}\left[\sigma_y-\eta(\sigma_x+\sigma_z)\right]\\ \varepsilon_z&=\frac{1}{E}\left[\sigma_z-\eta(\sigma_x+\sigma_y)\right]\end{aligned} \tag{9.7.54}$$

As:

$$\sigma_x=\sigma_1=\tau \qquad \sigma_y=\sigma_2=-\tau \qquad \sigma_z=0 \tag{9.7.55}$$

We have:

$$\varepsilon_x=\frac{1}{E}[\tau+\eta\tau]=\frac{(1+\eta)}{E}\tau \quad \text{and} \quad \varepsilon_y=\frac{1}{E}[-\tau-\eta\tau]=-\frac{(1+\eta)}{E}\tau \tag{9.7.56}$$

Therefore:

$$\overline{\mathrm{O}a'}=\overline{\mathrm{O}a}+\overline{\mathrm{O}a}\varepsilon_y=\overline{\mathrm{O}a}(1+\varepsilon_y)=\overline{\mathrm{O}a}\left[1-\frac{(1+\eta)}{E}\tau\right] \tag{9.7.57}$$

Then the length $\overline{\mathrm{O}a'}$ decrease if τ increase.

We also have:

$$\overline{\mathrm{O}b'}=\overline{\mathrm{O}b}+\overline{\mathrm{O}b}\varepsilon_x=\overline{\mathrm{O}b}(1+\varepsilon_x)=\overline{\mathrm{O}b}\left[1+\frac{(1+\eta)}{E}\tau\right] \tag{9.7.58}$$

Then the length $\overline{\mathrm{O}b'}$ decrease if τ increase.

For the angle of the right triangle $\mathrm{O}a'b'$, we have:

$$\tan\left(\widehat{\mathrm{O}a'b'}\right)=\tan\left(\frac{1}{2}\left(\frac{\pi}{2}+\gamma\right)\right)=\tan\left(\frac{\pi}{4}+\frac{\gamma}{2}\right)=\frac{\overline{\mathrm{O}b'}}{\overline{\mathrm{O}a'}}=\frac{\overline{\mathrm{O}b}\left[1+\dfrac{(1+\eta)}{E}\tau\right]}{\overline{\mathrm{O}a}\left[1-\dfrac{(1+\eta)}{E}\tau\right]}=\frac{1+\dfrac{(1+\eta)}{E}\tau}{1-\dfrac{(1+\eta)}{E}\tau} \tag{9.7.59}$$

But using trigonometric identities (see section Trigonometry page 2519):

$$\tan\left(\frac{\pi}{4}+\frac{\gamma}{2}\right)=\frac{\tan\left(\dfrac{\pi}{4}\right)+\tan\left(\dfrac{\gamma}{2}\right)}{1-\tan\left(\dfrac{\pi}{4}\right)\tan\left(\dfrac{\gamma}{2}\right)}=\frac{1+\tan\left(\dfrac{\gamma}{2}\right)}{1-\tan\left(\dfrac{\gamma}{2}\right)} \tag{9.7.60}$$

As $\tan\left(\dfrac{\gamma}{2}\right)\cong\dfrac{\gamma}{2}$ when γ is small as proved in the section of sequences and series, we have:

$$\frac{1+\dfrac{\gamma}{2}}{1-\dfrac{\gamma}{2}}=\frac{1+\dfrac{(1+\eta)}{E}\tau}{1-\dfrac{(1+\eta)}{E}\tau} \tag{9.7.61}$$

Therefore:

$$\frac{\gamma}{2}=\frac{1+\eta}{E}\tau \tag{9.7.62}$$

Finally, we fall back on the relation giving the "shear modulus" or "Coulomb module" we had given earlier without proof:

$$\boxed{\frac{\tau}{\gamma}=G=\frac{E}{2(1+\eta)}} \tag{9.7.63}$$

9.7.1.2.3 Compressibility Modulus (bulk modulus)

We still have to see the origin of mathematical expression from another modulus as important as the shear modulus: the bulk modulus.

Given the system of equations determined in the previous study:

$$\begin{aligned}\varepsilon_x&=\frac{1}{E}\left[\sigma_x-\eta(\sigma_y+\sigma_z)\right]\\ \varepsilon_y&=\frac{1}{E}\left[\sigma_y-\eta(\sigma_x+\sigma_z)\right]\\ \varepsilon_z&=\frac{1}{E}\left[\sigma_z-\eta(\sigma_x+\sigma_y)\right]\end{aligned} \tag{9.7.64}$$

If the forces applied on the cube are equal in intensity, we have:

$$\sigma_x=\sigma_y=\sigma_z=\sigma \tag{9.7.65}$$

Which gives us:

$$\begin{aligned}\varepsilon_x&=\frac{1}{E}\left[\sigma-\eta(\sigma+\sigma)\right]=\frac{\sigma}{E}(1-2\eta)\\ \varepsilon_y&=\frac{1}{E}\left[\sigma-\eta(\sigma+\sigma)\right]=\frac{\sigma}{E}(1-2\eta)\\ \varepsilon_z&=\frac{1}{E}\left[\sigma-\eta(\sigma+\sigma)\right]=\frac{\sigma}{E}(1-2\eta)\end{aligned} \tag{9.7.66}$$

Summing the terms according to the principle of linear superposition of forces:

$$\varepsilon_x+\varepsilon_y+\varepsilon_z=\frac{3\sigma}{E}(1-2\eta) \tag{9.7.67}$$

But:

$$\varepsilon_x+\varepsilon_y+\varepsilon_z=\frac{|\Delta L_x|}{L_{x0}}+\frac{|\Delta L_y|}{L_{y0}}+\frac{|\Delta L_z|}{L_{z0}} \tag{9.7.68}$$

That is:

$$\varepsilon_x L_{x0}L_{y0}L_{z0}+\varepsilon_y L_{x0}L_{y0}L_{z0}+\varepsilon_z L_{x0}L_{y0}L_{z0}=|\Delta L_x|L_{y0}L_{z0}+|\Delta L_y|L_{x0}L_{z0}+|\Delta L_z|L_{x0}L_{y0} \tag{9.7.69}$$

Therefore:

$$V_0(\varepsilon_x+\varepsilon_y+\varepsilon_z)=\Delta V \tag{9.7.70}$$

So:

$$\varepsilon_x+\varepsilon_y+\varepsilon_z=\frac{\Delta V}{V_0} \tag{9.7.71}$$

Finally, we find for the relative change in volume of a solid after deformation:

$$\boxed{\frac{\Delta V}{V_0}=\sigma\frac{3(1-2\eta)}{E}} \tag{9.7.72}$$

That we also write sometimes

$$\varepsilon_V=\sigma\frac{3(1-2\eta)}{E}=\sigma\kappa \tag{9.7.73}$$

Therefore:

$$\boxed{\kappa=\frac{\varepsilon_V}{\sigma}} \tag{9.7.74}$$

with κ being by definition the "compression coefficient".

We then define the "bulk modulus" by:

$$\boxed{K=\frac{E}{3(1-2\eta)}} \tag{9.7.75}$$

Let us notice that when the Poisson coefficient η is about 0.33 then K is equal to E (metallic materials are close to this case) and when the Poisson's ratio approaches 0.5 then K approaches infinity and thus the material is incompressible (elastomers approach such an incompressible behaviour).

9.7.1.2.4 Flexural Modulus (bending modulus)

The "flexural modulus" or "bending modulus" is the ratio of stress to strain in flexural deformation, or the tendency for a material to bend. It is determined from the slope of a stress-strain curve produced by a flexural test, and uses units of force per area. It is an intensive property

To study the flexural modulus we consider the following situation:

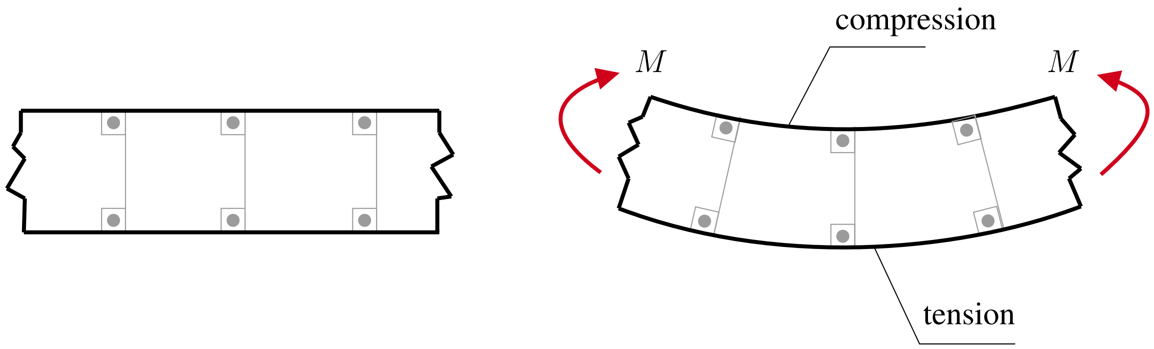


Figure 9.202: Example of a bar under flexural deformation

The above left figure shows a material in a static state. The right figure shows the same material but subject to a couple force momentum M (the height variation of the middle point is named the "deflection").

As the material undergoes on its surface a compression and at the opposite side a tension, so it should exist a border (a line or plane) where no constraint exists. This line or plane (it's rare that we are dealing with a material having only two dimensions ...) is named "neutral plane" (N.P.). This neutral plane will serve us as a reference for defining the bending stress.

Now that this plane is defined, let us consider the following figures:

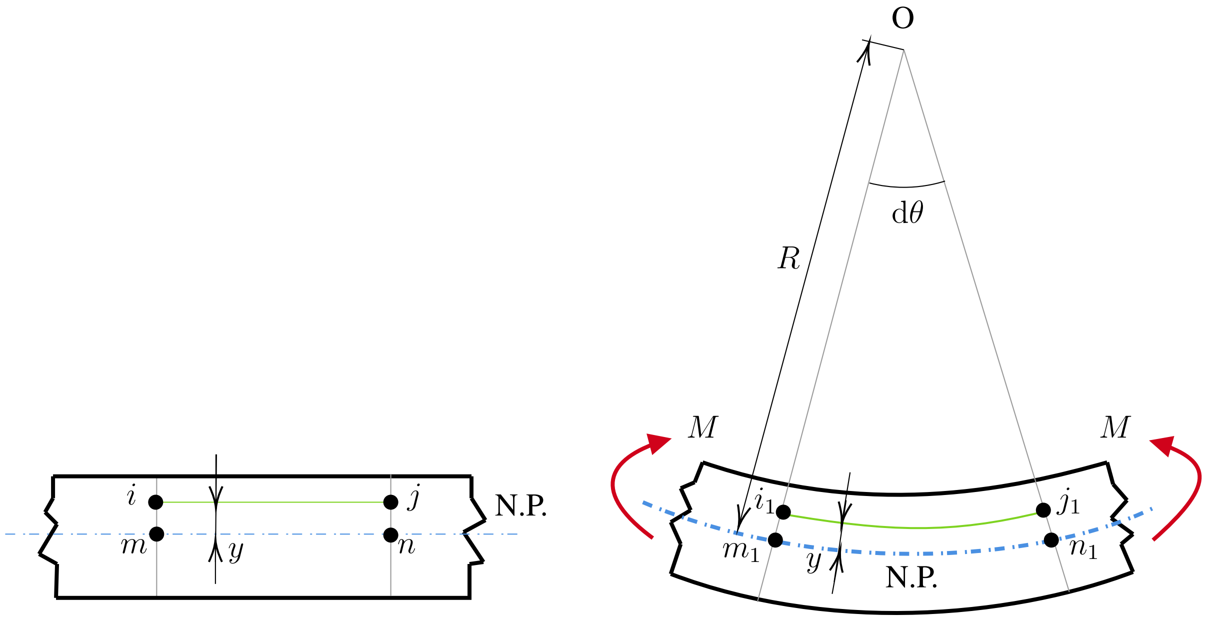

Figure 9.203: Illustration of the neutral plane to determine the flexural modulus

Given R be the bar (cylinder, plate, parallelepiped, ...) radius of curvature. The deformation on the segment $\overline{i_1j_1}$ defined by the relation:

$$\varepsilon_{NP}=\frac{\overline{i_1j_1}-\overline{ij}}{ij} \tag{9.7.76}$$

The lengths $\overline{mn}$ and $\overline{ij}$ are defined by:

$$\overline{ij}=\overline{mn}=\overline{m_1n_1}=R\mathrm{d}\theta \tag{9.7.77}$$

and the length $\overline{i_1j_1}$ by:

$$\overline{i_1j_1}=(R-y)\mathrm{d}\theta \tag{9.7.78}$$

thus expression of the deformation becomes:

$$\varepsilon_{NP}=\frac{(R-y)\mathrm{d}\theta-R\mathrm{d}\theta}{R\mathrm{d}\theta}=-\frac{y}{R} \tag{9.7.79}$$

indicating that the deformation varies linearly with y.

We can define the flexural modulus by:

$$E=\frac{\sigma}{\varepsilon_{NP}}=\frac{-\sigma R}{y} \tag{9.7.80}$$

Let us consider the static state of the bar. The sum of traction and compression constraints are therefore zero. Indeed, we see it well if we look at the diagram below:

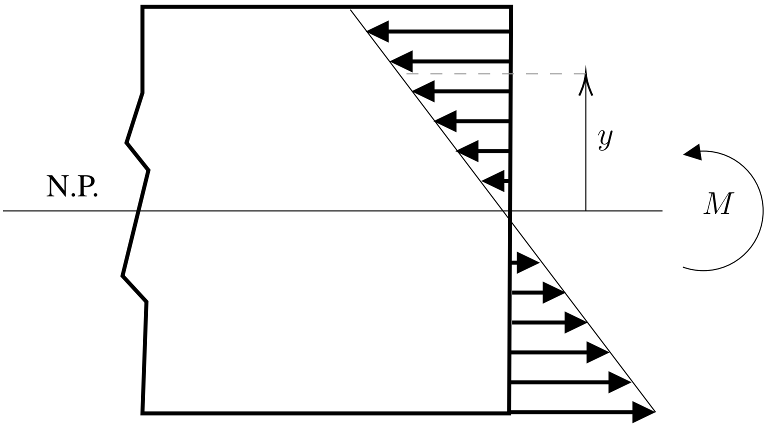

Figure 9.204: **Zoom on the flexion plane**

Let us consider $\sigma\mathrm{d}S$ the force acting on a surface element $\mathrm{d}S$. We can consider the equilibrium of forces in the static state such that:

$$\sum F=\int\limits_S\sigma\mathrm{d}S=0 \tag{9.7.81}$$

Substituting the expression of the constraint obtained previously:

$$\int\limits_S-\frac{Ey}{R}\mathrm{d}S=-\frac{E}{R}\int_S y\mathrm{d}S=0 \tag{9.7.82}$$

by assuming linear the strain characteristic in a first approximation, therefore $E=c^{te}$.

By simplifying a little bit:

$$\int y\mathrm{d}S=0 \tag{9.7.83}$$

If we multiply the integral by σ then the relation should be equal to the force momentum (torque) applied such that:

$$\int_S y\mathrm{d}S=M \tag{9.7.84}$$

By substituting by the expression of the stress obtained previously:

$$M=\int_S \sigma y\mathrm{d}S=\int_S -\frac{Ey^2}{R}\mathrm{d}S=-\frac{E}{R}\int_S y^2\mathrm{d}S \tag{9.7.85}$$

Which brings us to define the term:

$$\boxed{I=\int y^2\mathrm{d}S} \tag{9.7.86}$$

that engineers named the "moment of inertia of the bar relative to the neutral plane" or "static moment of inertia". This term is a measure of the rigidity of the cross section of the bar from a geometric point of view, without consideration of material properties.

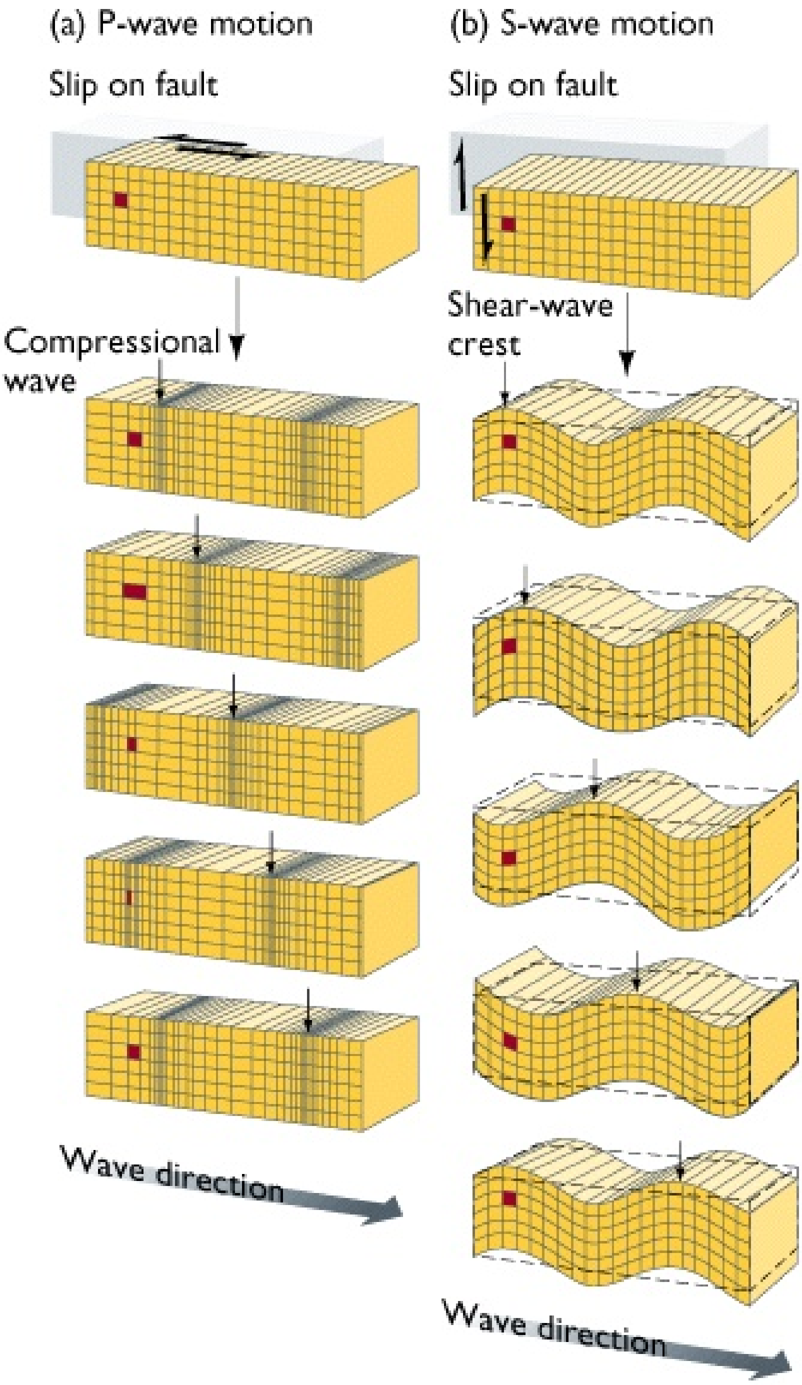
Substituting this relationship in the bending stress equation, we get the general "flexural modulus" relation:

$$\boxed{E=\frac{MR}{I}=-\frac{\sigma R}{y}} \tag{9.7.87}$$

The challenge for the engineer is often to locate the plane mathematically neutral ... We will see how to calculate the latter in some special cases in the section of Mechanical Engineering.

9.7.1.2.5 Tranverse Wave in Solids

The transverse sound waves or "S-waves" ("shear waves"), at the opposition of "P-waves" that are compression/dilation type wave[29], for occur only in solids and typical of seismic events. The successive layers of the medium move laterally without volume, density or pressure, change:



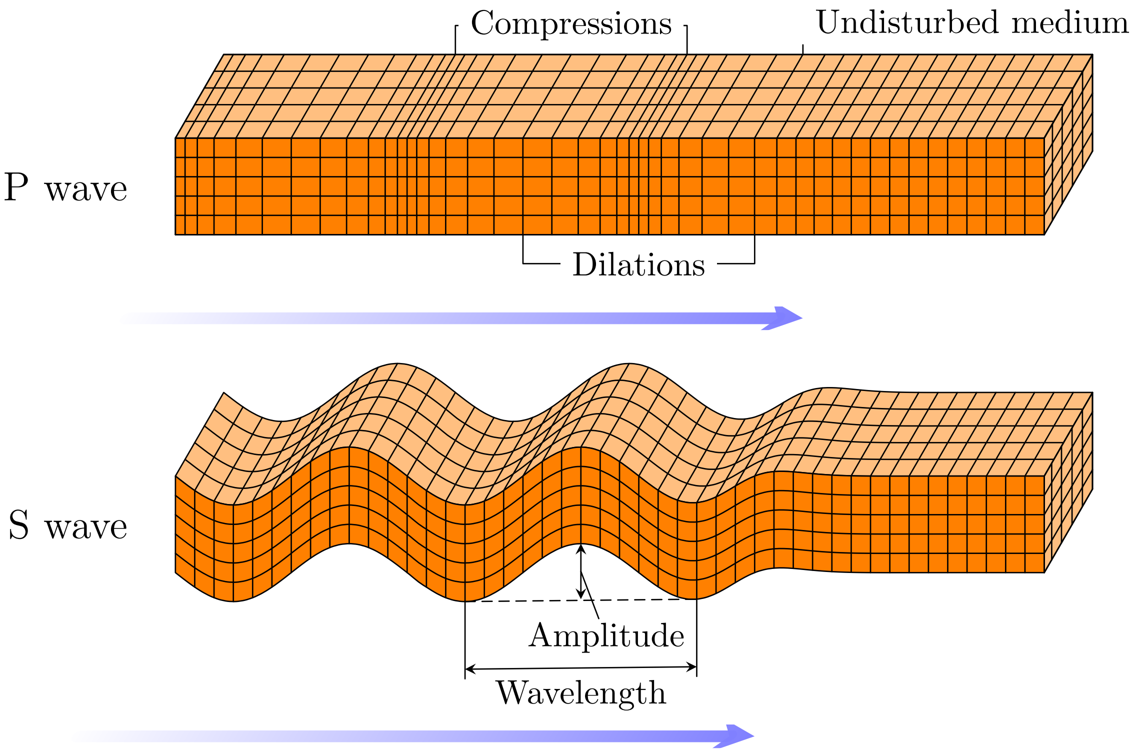
(a) P-wave motion
Slip on fault
Compressional wave
Wave direction
(b) S-wave motion
Slip on fault
Shear-wave crest
Wave direction

Figure 9.205: **P-wave and S-Wave in solids**

Or for those who prefer a better quality illustration:

---

[29] "S" stands for "secondary" and the "P" form "primary"



Compressions
Undisturbed medium
P wave
Dilations
S wave
Amplitude
Wavelength

Figure 9.206: P-wave and S-Wave in solids made with TikZ

and focusing only on the S-waves we have for the front view schematically:

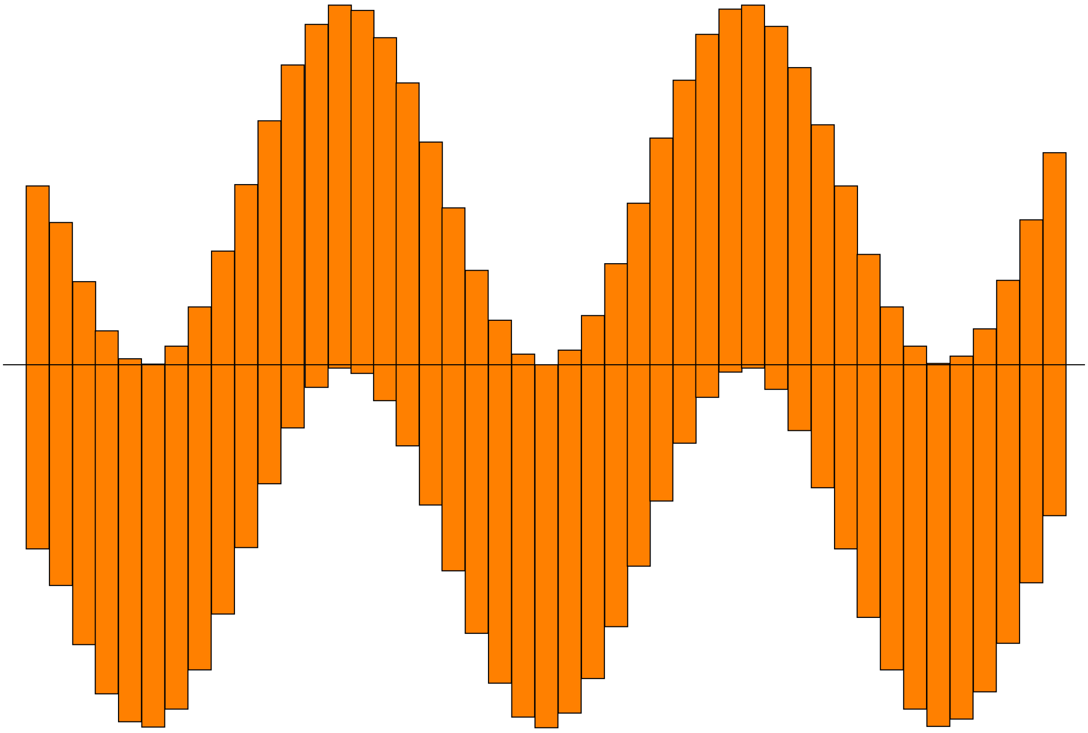


Figure 9.207: S-Wave front view

The medium is deformed in the same way that you can distort a book or ream of paper laid both on a flat table by pushing up horizontally the cover or respectively the first paper page. Neither the book nor the train not change volume!

The way to obtain the wave equation for transverse waves is almost the same as for a string (see section Wave Mechanics page 3487). Let us take three contiguous thin planar layers of the medium (see figure below):

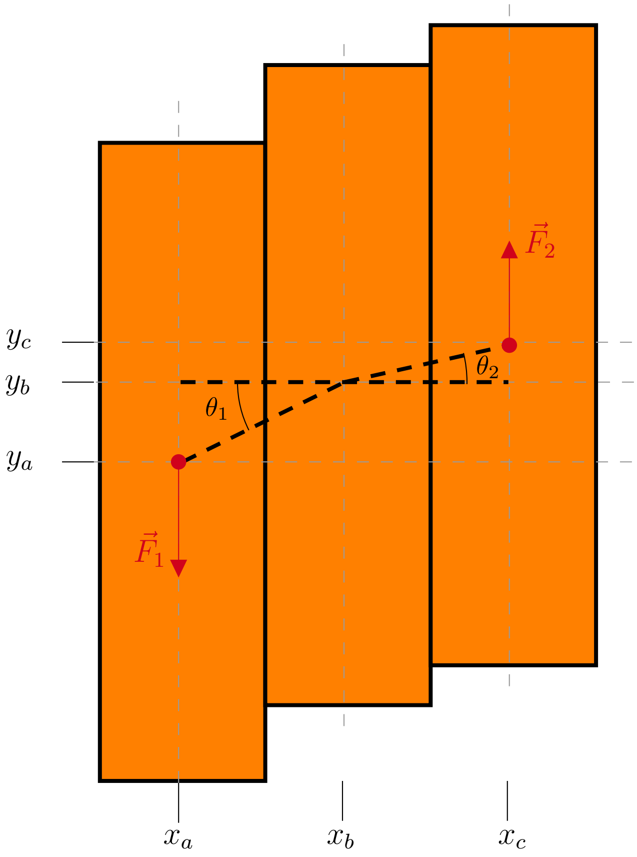

Figure 9.208: **Zoom on three layers of a shear wave**

The centers of the layers being on x_a, x_b, x_c with:

$$x_c - x_b = x_b - x_a = \Delta x \tag{9.7.88}$$

The transversely displacement of the three adjacent layers is y_a, y_b, y_c. The angles of deformation respectively between the layer b and the layer a, and, between the layer c and layer b are in the first order Taylor approximation (see section Sequences and Series page 1703):

$$\begin{aligned}\theta_1 &= \arctan\left(\frac{y_b - y_a}{x_b - x_a}\right) \cong \frac{y_b - y_a}{x_b - x_a}\\ \theta_2 &= \arctan\left(\frac{y_c - y_b}{x_c - x_b}\right) \cong \frac{y_c - y_b}{x_c - x_b}\end{aligned} \tag{9.7.89}$$

If we calculate the forces between the layers for a piece of layer of surface S, we get:

$$\begin{aligned}\frac{F_1}{S}&=G\frac{y_b-y_a}{\mathrm{d}x}\\ \frac{F_2}{S}&=G\frac{y_c-y_b}{\mathrm{d}x}\end{aligned} \tag{9.7.90}$$

where G is as we know the shear modulus of the medium. The resultant force is then:

$$F_b=F_2-F_1=SG\left(\frac{y_c-y_b}{\mathrm{d}x}-\frac{y_b-y_a}{\mathrm{d}x}\right) \tag{9.7.91}$$

The force of the layer F_b will be equal at any time to the product of the mass of the piece of layer b, of thickness $\mathrm{d}s$, of surface S and density ρ, multiplied by the acceleration of the layer given by:

$$\left(\frac{\partial^2 y}{\partial t^2}\right)_b \tag{9.7.92}$$

Then we have:

$$F_b=ma_b=\rho S\mathrm{d}x\left(\frac{\partial^2 y}{\partial t^2}\right)_b=SG\left(\frac{y_c-y_b}{\mathrm{d}x}-\frac{y_b-y_a}{\mathrm{d}x}\right) \tag{9.7.93}$$

Which gives:

$$\left(\frac{\partial^2 y}{\partial t^2}\right)_b=\frac{G}{\rho}\frac{\left(\dfrac{y_c-y_b}{\mathrm{d}x}-\dfrac{y_b-y_a}{\mathrm{d}x}\right)}{\mathrm{d}x}=\frac{G}{\rho}\left(\frac{\partial^2 y}{\partial x^2}\right)_b \tag{9.7.94}$$

What we have just deduce for any value x_b is true for any coordinate:

$$\boxed{\frac{\partial^2 y}{\partial t^2}=\frac{G}{\rho}\frac{\partial^2 y}{\partial x^2}} \tag{9.7.95}$$

and the transverse wave velocity is therefore:

$$\boxed{v=\sqrt{\frac{G}{\rho}}} \tag{9.7.96}$$

Indeed, the ratio G/ρ has the units of the square of a speed:

$$\frac{G}{\rho}=\frac{\dfrac{\mathrm{N}}{\mathrm{m}^2}}{\dfrac{\mathrm{kg}}{\mathrm{m}^3}}=\frac{\dfrac{\mathrm{kg}\cdot\mathrm{m}}{\mathrm{m}^2\cdot\mathrm{s}^2}}{\dfrac{\mathrm{kg}}{\mathrm{m}^3}}=\frac{\mathrm{kg}\cdot\mathrm{m}\cdot\mathrm{m}^3}{\mathrm{m}^3\cdot\mathrm{s}^2\cdot\mathrm{kg}}=\frac{\mathrm{m}^2}{\mathrm{s}^2} \tag{9.7.97}$$

It we finish therefore with a wave equation (recall) of the form of a Poisson's equation (more particularly it is a "d'Alembert's equation" as we know), i.e.:

$$\frac{\partial^2 y}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2 y}{\partial t^2} \tag{9.7.98}$$

Transverse waves propagate only in solids and therefore we can not hear them unless we transform them into longitudinal waves (P waves) by mechanical or electrical means. The transverse waves can be transmitted along a bar or rod of any or even a metal wire, and this without the need that the latter is under stress. Even if the metal wire is under stress, the speed of shear waves is not dependent on the stress (obviously in a given limit...). This is the high shear modulus G of steel that gives electric guitars that characteristic sound.

Another remarkable case of transverse waves (shear waves) is the seismic wave has we have already mention it. There are seismic shear waves and also longitudinal waves or pressure as we have show it also earlier. Shear waves propagate in the Earth's crust at the speed of $3,600\,[\text{m}\cdot\text{s}^{-1}]$ and the pressure wave at the speed of $6,000\,[\text{m}\cdot\text{s}^{-1}]$. During an earthquake or an atomic explosion, the two types of waves will be produced, but as the waves travel at different speeds, they will not arrive at the same time at remote sensing stations. It is from this difference in arrival times that we can determined the distance at the epicenter. The direction is obtained from the direction of the oscillations. Only sufficiently distant stations to receive both types of wave separately can make the determination of the epicenter.

To summarize, we have for longitudinal waves in a solid (see section Music Mathematics page 8202):

$$\boxed{\frac{\partial^2\xi}{\partial t^2}=\frac{E}{\rho}\frac{\partial^2\xi}{\partial x^2}} \tag{9.7.99}$$

and for transverse waves:

$$\boxed{\frac{\partial^2 y}{\partial t^2}=\frac{G}{\rho}\frac{\partial^2 y}{\partial x^2}} \tag{9.7.100}$$

For the details of the mathematical developments in the gas and solid about propagation waves, the reader should read the section of Mathematical Music (Acoustic) page 8195.

9.7.2 Liquids (fluid mechanics)

A liquid is a nearly incompressible fluid[30] that conforms to the shape of its container but retains a (nearly) constant volume independent of pressure. As such, it is one of the four fundamental states of matter (the others being solid, gas, and plasma), and is the only state with a definite volume but no fixed shape. A liquid is made up of tiny vibrating particles of matter, such as atoms, held together by intermolecular bonds. Water is, by far, the most common liquid on Earth. Like a gas, a liquid is able to flow and take the shape of a container. Most liquids resist compression, although others can be compressed. Unlike a gas, a liquid does not disperse to fill every space of a container, and maintains a fairly constant density. A distinctive property of the liquid state is surface tension, leading to wetting phenomena.

The density of a liquid is usually close to that of a solid, and much higher than in a gas. Therefore, liquid and solid are both termed condensed matter. On the other hand, as liquids and gases share the ability to flow, they are both named "fluids". Although liquid water is abundant on Earth, this state of matter is actually the least common in the known universe, because liquids require a relatively narrow temperature/pressure range to exist. Most known matter in the universe is in gaseous form (with traces of detectable solid matter) as interstellar clouds or in plasma form within stars.

The distinction between liquid and gas is subtle. However, we can say that the proper volume of liquid manifests the existence of cohesiveness due to a fairly high density (van der Waals bonds); this cohesion disappears with the proper volume of a gas.

If we compare the fluids with solids, the first that comes concerns the isotropy (properties are the same in all spatial directions) of conventional fluids that is always satisfied (at least if we do not act on the fluid directly!).

In what follows, we will address the fluid mechanics theory in increasing difficulty and redundancy by trying to keep it simple and stupid as possible. First, we will be prove that the properties of a static fluid are isotropic (Pascal's theorem). Using this result, it will be easier for us to understand Bernoulli's theorem that will allow us, among others, to define the concept of "hydrostatic pressure". Then we will build a very important model for fluid dynamics, known as the "Navier-Stokes equations", which has usages almost all possible existing areas of science (astrophysics, quantum mechanics, meteorology, ...). This fluid dynamics model is quite big in theoretical developments and experimental results and can be considered as difficult to approach. However, for ease of reading, we chose not to address it by use of tensor calculus. We have made sure that the tensor variables appear by themselves following the simple previous vector analysis results we will get. Once the Navier-Stokes equations determined and proved, we will see that we can find the expression of Bernoulli's theorem from these equations.

---

[30] In fact nothing as far as we know is absolutely incompressible but when in the study we do the relative variations of pressure and speed a small enough we consider the fluid as being incompressible.

The Navier-Stokes equations and finally used with Finite Element Methods to make numerical simulations of shapes to optimize the penetration or movement of objects in water or in the air:

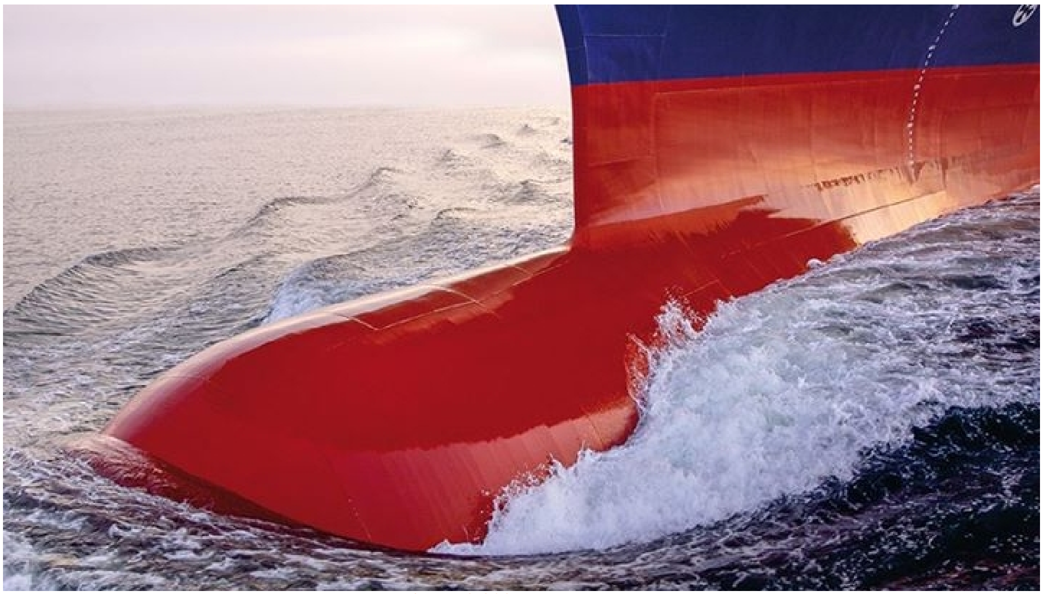

Figure 9.209: **Bulbous bow**

On the picture above we see a bulbous bow that is a protruding bulb at the bow (or front) of a ship and using the concept of destructive interference of waves to cancel the wave produced at the back by the bow. Large ships with bulbous bows generally have a twelve to fifteen percent better fuel efficiency than similar vessels without them.

Fluid dynamics, or "hydrodynamic" is by far the field of Classical Mechanics the less easy to understand as regards to the descriptions and predictions. This is why the Bernoulli's theorem is often used, not to explain in detail the behaviour of a fluid, but to make a qualitative description for it.

Caution! To determine whether Statistical Mechanics or the Continuum Mechanics formulation of fluid dynamics should be used to model a situation, we use the "Knudsen number". This is a dimensionless number defined as the ratio of the molecular mean free path length to a representative physical length scale. This length scale could be, for example, the radius of a body in a fluid. If the Knudsen number is near or greater than one, the mean free path of a molecule is comparable to a length scale of the problem, and the continuum assumption of fluid mechanics is no longer a good approximation. In such cases, statistical methods should be used.

Commonly for the average individual, "fluids" are always associated with liquids. However in physics "fluid" is a liquid, gas, or other material that may continuously move and deform (flow) under an applied shear stress, or external force. They have zero shear modulus, or, in simpler terms, are substances which cannot resist any shear force applied to them. However in geology it's a little bit more complicated than this because some things that we consider to be solid will flow if given enough time.

Below we can see the gas dioxide nitrogen (NO_2) flowing from an Erlenmeyer flask into a beaker initially full of air (dioxide nitrogen has a mass and therefore a weight due to gravity greater than those of the different components that air is made of):

9.7.2.1 Pascal's Theorem

Definition (#9.7.472): The "Pascal's law" or the "principle of transmission of fluid-pressure" (also named "Pascal's Principle") is a principle in fluid mechanics that states that a pressure change occurring anywhere in a confined incompressible fluid is transmitted throughout the fluid such that the same change occurs everywhere.

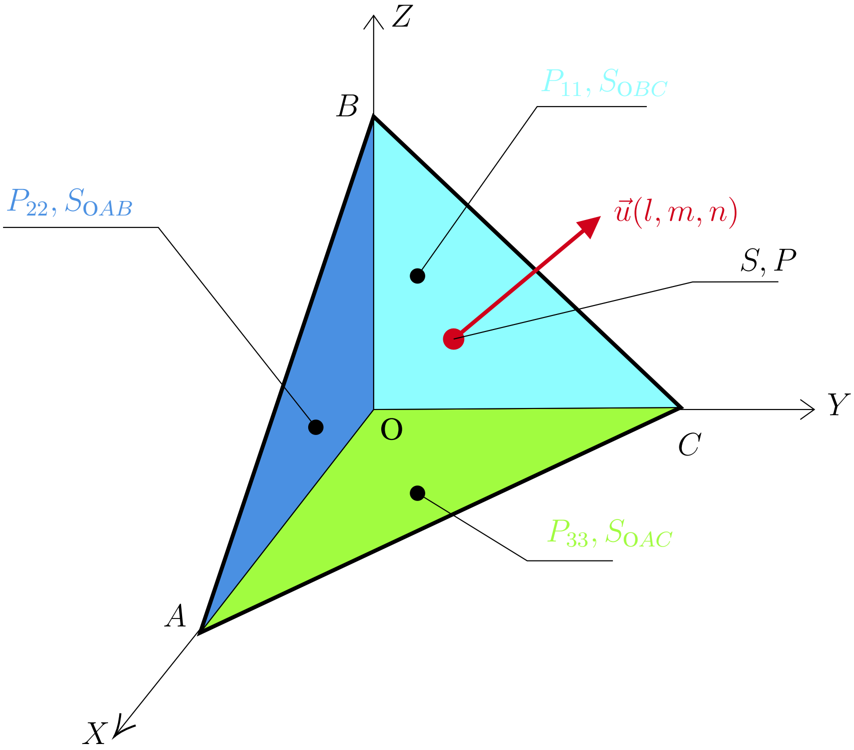

Figure 9.210: **Elementary tetrahedron to introduce Pascal's theorem**

If we consider the forces acting, in the absence of movement on an elementary tetrahedron OABC of volume V, it is always possible to choose a sufficiently small volume in order to have a uniform pressure on all the faces of the tetrahedron .

Given $P_{11}, P_{22}, P_{33}, P$, the fluid reaction pressures due to external constraints soliciting the respective faces OBC, OAB, OAC and ABC of respecting surfaces $S_{\text{O}BC}, S_{\text{O}AB}, S_{\text{O}AC}, S$. Given also the cosine direction (see section Vector Calculus page 1811) of the unit vector normal $\vec{n}$ to the surface ABC.

The system being in equilibrium, the resultant $\vec{R}$ of the of the forces of reaction of the system is zero. So we have the following equations resulting from the projection along the three coordinate axes:

$$\begin{aligned}R_x &= P_{11}S_{\text{O}BC} - PS_{\text{O}BC} = 0\\ R_y &= P_{22}S_{\text{O}AB} - PS_{\text{O}AB} = 0\\ R_y &= P_{33}S_{\text{O}AC} - PS_{\text{O}AC} = 0\end{aligned} \tag{9.7.101}$$

By elementary simplification, it comes:

$$\begin{aligned} P-P_{11}&=0\\ P-P_{22}&=0\\ p-P_{33}&=0 \end{aligned} \tag{9.7.102}$$

We then get the following relation:

$$\boxed{P=p_{11}=p_{22}=p_{33}} \tag{9.7.103}$$

The major conclusion is that in any point of a fluid pressure is independent of the direction of the normal $\vec{n}$ to the elementary surface on which it is exercised.

In other words, by the Newton's principle of action and reaction, we are led to state the "Pascal's theorem" and "Pascal's principle": The incompressible fluids (in equilibrium) transmit integrally and in all directions, the pressures applied to them.

This theorem is fundamental both in fluid mechanics and gas mechanics and the practical implications are huge. This theorem explains among others the famous "hydrostatic paradox" as what the pressure of a liquid on the bottom of a container is independent of its shape, and also of the bottom surface but only depends on the water level in the recipient. This theorem is the basis for the design of many hydraulic machines!

Let's look at a very clear illustration. Consider the following diagram (we made an example in U, although if the majority of hydraulic systems are linear):

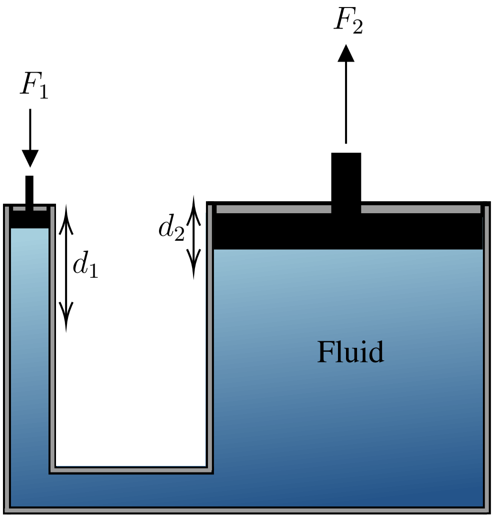

Figure 9.211: **Typical hydraulic machine (elevator, hydraulic jack)**

What is happening exactly? Well on the left, we have the force F_1 that generates the pressure:

$$P_1=\frac{F_1}{S_1} \tag{9.7.104}$$

and by the Pascal's principle, we must find the same pressure on the other side such that:

$$P_2=P_1=\frac{F_2}{S_2} \tag{9.7.105}$$

It follows immediately the very important relation in practice:

$$\boxed{P_1S_2=F_1\frac{S_2}{S_1}=F_2} \qquad (9.7.106)$$

So we have a force multiplier! Warning! The principle of the hydraulic machine is to have a fantastic force multiplier but in no case it multiplies the work W! So by the principle of conservation of energy, we have:

$$W_1=F_1d_1=W_2=F_2d_2 \qquad (9.7.107)$$

and then it comes:

$$d_1=\frac{F_1}{F_2}d_2=\frac{P_1/S_1}{P_2/S_2}d_2=\frac{P_1/S_1}{P_1/S_2}d_2=\frac{S_2}{S_1}d_2 \qquad (9.7.108)$$

Therefore, in counterpart of the force multiplication effect, the energy conservation, the primary force must travel a greater distance.

9.7.2.2 Viscosity

The viscosity of a fluid is a measure of its resistance to gradual deformation by shear stress or tensile stress. For liquids, it corresponds to the informal concept of "thickness"; for example, honey has a much higher viscosity than water.

Viscosity is a property arising from collisions between neighbouring particles in a fluid that are moving at different velocities. When the fluid is forced through a tube, the particles which compose the fluid generally move more quickly near the tube's axis and more slowly near its walls; therefore some stress (such as a pressure difference between the two ends of the tube) is needed to overcome the friction between particle layers to keep the fluid moving. For a given velocity pattern, the stress required is proportional to the fluid's viscosity.

A fluid that has no resistance to shear stress is known as an ideal or inviscid fluid. Zero viscosity is observed only at very low temperatures in superfluids. Otherwise, all fluids have positive viscosity, and are technically said to be viscous or viscid. In common parlance, however, a liquid is said to be viscous if its viscosity is substantially greater than that of water, and may be described as mobile if the viscosity is noticeably less than water. A fluid with a relatively high viscosity, such as pitch, may appear to be a solid.

In fluid mechanics, it is useful to consider several types of fluids with characteristics that differentiate them. This is especially useful for simulations while remaining consistent with the experimental observations (see section Marine & Weather Engineering page 8239).

Definitions (#9.7.473): We define the "viscosity" μ by the internal forces opposing the movement of the various layers composing the fluid. We distinguish two type of viscosity:

D1. The "dynamic viscosity μ_d" also simply named "coefficient of viscosity":

$$\boxed{\mu_d=\frac{\mathrm{d}F}{\partial_z v\mathrm{d}S}} \qquad (9.7.109)$$

which unit is the Poiseuille: [PI] (equivalent to the pascal-second $[\text{Pa}\cdot\text{s}]$, or $[\text{N}\cdot\text{s}\cdot\text{m}^{-2}]$, or $[\text{kg}\cdot\text{m}^{-1}\cdot\text{s}^{-1}]$), $\mathrm{d}F$ the variation of the frictional force between two infinitely neighbouring layers, $\partial_z v$ being the variation in speed by the distance between two infinitely neighbouring layers and in $[\text{s}^{-1}]$ and $\mathrm{d}S$ being the considered surface $[\text{m}^2]$.

If a fluid is placed between two plates with a distance of 1 [m], and one plate is pushed sideways with a shear stress of one [Pa], and it moves at v meter per second, then it has a viscosity of $1/v$ $[\text{Pa}\cdot\text{s}]$.

For example, water at 293 [K] has a dynamic viscosity of 0.001 $[\text{Pa}\cdot\text{s}]$ while a typical motor oil could have a viscosity of about 0.25 $[\text{Pa}\cdot\text{s}]$. Here are some more dynamics viscosity values:

Material	**Temperature [K]**	μ_d **[Pa · s]**
Water	273	$1.8\cdot10^{-3}$
Water	293	$1.0\cdot10^{-3}$
Water	313	$0.7\cdot10^{-3}$
Alcohol (ethanol)	293	$1.2\cdot10^{-3}$
Glycerine	293	1.5
Light machine oil	313	$3.4\cdot10^{-2}$
Weight machine oil	313	$13.0\cdot10^{-2}$
Engine oil	313	$2.4\cdot10^{-1}$
Engine oil	373	$0.2\cdot10^{1}$
Mercury	293	$1.6\cdot10^{-3}$
Air	273	$1.7\cdot10^{-5}$
Air	293	$1.8\cdot10^{-5}$
Air	313	$1.9\cdot10^{-5}$
Water Vapour	393	$1.25\cdot10^{-5}$
Water Vapour	493	$1.64\cdot10^{-5}$
Ammonia	293	$1\cdot10^{-5}$
Nitrogen	293	$1.75\cdot10^{-5}$
Carbon dioxide	293	$1.5\cdot10^{-5}$
Hydrogen	293	$0.9\cdot10^{-5}$
Oxygen	293	$2\cdot10^{-5}$

Table 9.34: **Some dynamic viscosity values**

Conclusion: The Poiseuille is the viscosity of a fluid needing a force of 1 Newton to slide at a speed of 1 meter per second, two fluid layers of 1 square meter by a distance of 1 meter.

A transformation of the definition of dynamic viscosity gives (this relations must be remembered for later use!!):

$$\boxed{\tau=\frac{\mathrm{d}F}{\mathrm{d}S}=\mu_d\partial_z v} \tag{9.7.110}$$

That is:

$$\partial_z v=\frac{1}{\mu_d}\tau \tag{9.7.111}$$

D2. The "kinematic viscosity μ_k":

$$\boxed{\mu_k=\frac{\mu_d}{\rho}} \tag{9.7.112}$$

By definition fluids having the following characteristics:

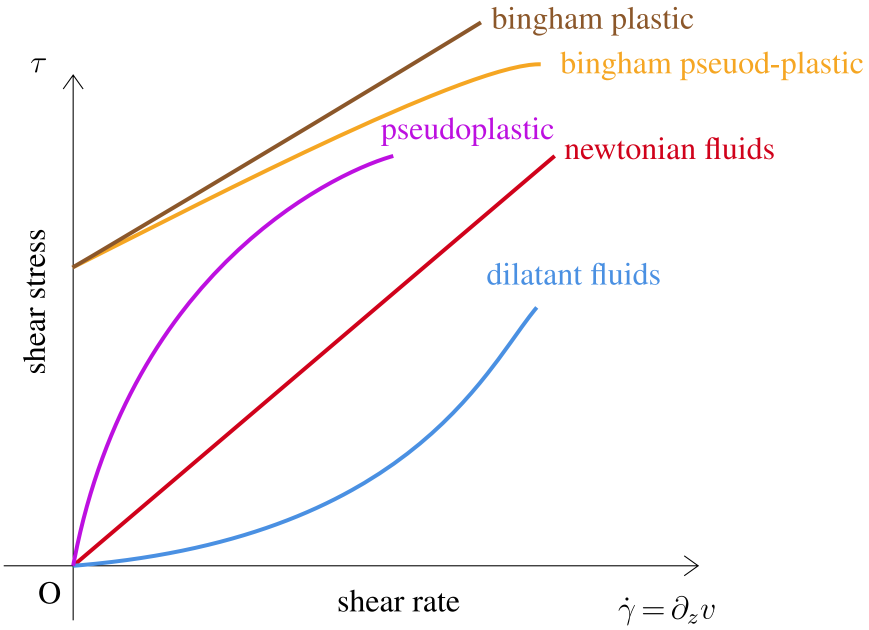

Figure 9.212: **Very approximative viscosity characteristics of different typical fluids**

There are still three other main types of fluids (among others!) not shown in the figure and whose viscosity is assumed to be zero. We then speak of "Pascalian fluids":

- "Perfect fluids": A fluid that can be completely characterized by its rest frame mass density ρ and isotropic pressure p. Specifically, perfect fluids have no shear stresses, viscosity, or heat conduction.
- "Semi-perfect fluids": A fluid that eventually conduct heat and whose heat capacity is only dependent of temperature.
- "Real fluids": A fluid with all possible complications that we observe in real life...

Remarks

R1. The behaviour of a perfect fluid is very different from that of a real fluid as small as the viscosity can be for the latter. Indeed, the perfect fluid because it has no viscosity, never dissipate kinetic energy. While a real fluid with a small viscosity effectively dissipates it very efficiently through turbulences.

R2. We will come back on the properties of the dynamic and kinematic viscosity during the proof of the Navier-Stokes-(Reynolds) equations.

R3. The fluids that are not Newtonians are named very generally in the literature "non-Newtonian fluids" ... and we will not deal with Ferrofluids in this textbook because they are theoretically outside the range of this textbook.

Non-Newtonian fluids thus have a deformation which depends on the force that we apply to them. The best example is the wet sand by the sea: when we hit the sand, it has the high viscosity of a solid, whereas when we quietly press on it, it behaves like a paste. Moreover, some non-Newtonian fluids have properties such that it is possible for an individual to run on it without sinking or sink staying in position...

9.7.2.2.1 Poiseuille's law

In 11835 (holocene calendar) a French doctor, Jean Leonard Marie Poiseuille, made a series of careful experiments to determine how a viscous fluid flows through a narrow pipe. His goal was to understand the dynamics of blood flow in humans. Blood plasma behaves like a Newtonian fluid, while blood does not. Almost half of the volume of the normal blood is made large enough cells to disrupt laminar flow, especially when they come in contact with the vessel walls, a phenomenon that becomes important in very narrow capillaries. However, the analysis of Poiseuille applies to flow in the veins and larger arteries and it has great value, although it is a little bit simplistic.

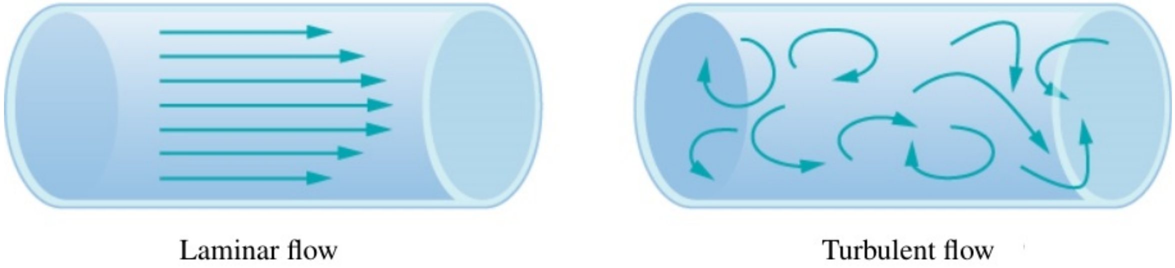

Figure 9.213: Laminar vs Turbulent flow (source: OpenStax)

The result of Poiseuille can be established by considering the fluid in a pipe as formed by concentric cylindrical layers oriented along an x-axis of radius r moving at speeds which decrease from the center (circular symmetry assumed).

Then the relation defining the viscosity is:

$$\boxed{F=\mu_d S\frac{\mathrm{d}v_x}{\mathrm{d}r}} \tag{9.7.113}$$

Remark

In some textbooks the definition is given as:

$$\tau=\frac{F}{S}=\mu_d\frac{\mathrm{d}v_x}{\mathrm{d}r} \tag{9.7.114}$$

That is the stress τ of a Newtonian fluid is assumed to be directly proportional to the rate at which the velocity field is changing as we move up.

What gives us the viscous force on the cylinder. The contact surface of each cylindrical layer of length l is given obviously by $S=2\pi rl$ and therefore:

$$F=\mu_d 2\pi rl\frac{\mathrm{d}v_x}{\mathrm{d}r} \tag{9.7.115}$$

The origin of the acceleration (i.e. the force) can be done only by a pressure difference such as:

$$\Delta PS=\Delta P\pi r^2=F \tag{9.7.116}$$

which brings us to write:

$$\Delta P\pi r^2=\mu_d 2\pi rl\frac{\mathrm{d}v_x}{\mathrm{d}r}\Rightarrow \mathrm{d}v_x=\frac{\Delta P}{2\mu_d l}r\mathrm{d}r \tag{9.7.117}$$

By integrating term by term, we get:

$$\int_0^{v_x} \mathrm{d}v_x = \frac{\Delta P}{2\mu_d} l \int_r^R r\mathrm{d}r \tag{9.7.118}$$

So we get the famous "law of viscous laminar flow" discovered by the French physicist Jean-Louis Marie Poiseuille in 11840 (holocene calendar):

$$\boxed{v_x = \frac{\Delta P}{4\mu_d l}(R^2 - r^2)} \tag{9.7.119}$$

widely used in medicine to calculate the blood flow speed in the veins, in hydraulic systems (to determine the pressure required to have a certain speed) and in wind tunnels (for the same reason as in hydraulic systems).

Turbulent air is not ideal for jet engines because it's less stable and is therefore more likely to induce vibration on fan blades, causing accelerated wear. So when it comes to fighter jets with intakes mounted rear of the nose (often just under leading edge of the wings), you need to make an effort to raise the intakes out of the way of the boundary layer between turbulent and laminar air:

The representing curve of the speed in function of r is a parabola whose summit is on the cylinder center axis ($r = 0$). That's why the above relation is often denoted:

$$v_x = \frac{v_0}{R^2}(R^2 - r^2) \tag{9.7.120}$$

So the speed is greater at the center than at the edges (that is quite intuitive). Differentiating this last relationship with respect to r, we immediately get the velocity gradient in function of r (calculation useful in practice).

The "volume flow" J (sometimes denoted D in small classes) carried by a cylindrical layer between r and $r + \mathrm{d}r$ is:

$$\boxed{J = \frac{\mathrm{d}V}{\mathrm{d}t} = v_x \mathrm{d}S = v_x(2\pi r\mathrm{d}r)} \tag{9.7.121}$$

Thus, the total flow is:

$$J=\int\limits_{0}^{R}\frac{\Delta P}{4\mu_d l}(R^2-r^2)2\pi r\mathrm{d}r \tag{9.7.122}$$

and we get the "Poiseuille law" for the viscous laminar flow:

$$J=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l} \tag{9.7.123}$$

Some books introduce the "resistance to flow" denoted R_f such that the Poiseuille law is finally written:

$$\boxed{J=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l}=\frac{\Delta P}{R_f}} \tag{9.7.124}$$

So we find the logical result that the flow rate increases with the pressure gradient $\Delta P/l$ and the radius of the tube, and decreases with the viscosity.

We find also a relation analogous to Ohm's law (see section Electrokinetics page 4233) where the potential difference is given by the resistance multiplied by the current so that the difference in pressure is given by the viscous resistance multiplied by the flaw. We will also come back on this relationship when we deal with the losses pressure in the pipes.

Remark

In the literature, the flow is sometimes denoted J, Q or D or even $\dot{V}$ ... In short, there is no standard notation as far as we know and we must do with ...

✍**Example:**

An air conditioning system is being designed to supply air at a gauge pressure of 0.054 [Pa] at a temperature of 293 [K]. The air is sent through an insulated, round conduit with a diameter of 0.18 [m]. The conduit is 20 [m] long and is open to a room at atmospheric pressure 101.30 [kPa]. The room has a length of 12 [m], a width of 6 [m], and a height of 3 [m] and we assume a constant pressure difference and using the viscosity $\mu_d=0.0181\;[\text{mPa}\cdot\text{s}]$.

The volume flow rate through the pipe, assuming laminar flow is then given by:

$$J=\frac{0.054\cdot\pi(0.09)^4}{8\cdot 0.0181\cdot 10^{-3}\cdot 20}\cong 3.84\cdot 10^{-3}\;[\text{m}^3\cdot\text{s}^{-1}] \tag{9.7.125}$$

The length of time to completely replace the air in the room is then by assuming constant flow equal to:

$$\Delta t=\frac{\Delta V}{J}=\frac{12\cdot 6\cdot 3}{3.84\cdot 10^{-3}}\cong 5.63\cdot 10^4=15.63\;[\text{h}] \tag{9.7.126}$$

The previous relation:

$$J=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l}=\frac{\Delta P}{R_f} \tag{9.7.127}$$

Is also denoted in some textbooks:

$$\Phi=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l} \tag{9.7.128}$$

and after rearranging we get:

$$\mu_d=\frac{\pi R^4}{8l\Phi}\Delta P \tag{9.7.129}$$

This is an expression well known to experimentally measure the dynamic viscosity of a fluid based on simple parameters (and dividing by ρ by definition we get the kinematic viscosity). Indeed, we just need a tank that has a source of liquid that maintains the liquid hight constant inside the tank and pipe at the bottom from which the liquid flows and know the difference of pressure between the top of the liquid in the tank and pipe separated from a vertical distance h. That's why the above relation can often be found as following in the literature:

$$\boxed{\mu_d=\frac{\pi R^4}{8l\Phi}\Delta P=\frac{\pi R^4}{8l\Phi}mgh} \tag{9.7.130}$$

Although rather a mess of constants appears in our formula for the kinematic viscosity μ_d, all are quite easily measured.

Remark

It seems that there is no analytical method to calculate the pressure drop of a pipe elbow.

9.7.2.2.2 Viscous force on a fluid element

Suppose again that we have a simple x directed velocity field whose velocity profile is the same as in the previous figure above (a horizontally oriented parabola). But as the flow is symmetric we can focus only on half of the pipe (i.e. half of the parabola).

Now let us consider in the bottom symmetric part of the pipe a small volume element with sides Δx, Δy and Δz, the bottom of which is located at y and the top at $y+\Delta y$. The fluid below at y is dragging the fluid above, something that we can write:

$$\tau_-(y)=-\mu_d\frac{\partial_x v_x(y)}{\partial y} \tag{9.7.131}$$

The total force at the bottom is as we already know the stress times the area $\Delta x\Delta y$ upon which it is acting:

$$\Delta F_-(y)=\tau_-(y)\Delta x\Delta z=-\mu_d\frac{\partial_x v_x(y)}{\partial y}\Delta x\Delta z \tag{9.7.132}$$

Respectively the faster fluid pulls forward the slower one with a total force:

$$\Delta F_+(y+\Delta y)=\tau_+(y+\Delta y)\Delta x\Delta z=+\mu_d\frac{\partial_x v_x(y+\Delta y)}{\partial y}\Delta x\Delta z \tag{9.7.133}$$

With the two relation above we see that the total viscous force on the fluid in our volume element can be written:

$$\Delta F_x=\Delta F_-(y)+\Delta F_+(y+\Delta y)=\mu_d\left[-\frac{\partial_x v_x(y)}{\partial y}+\frac{\partial_x v_x(y+\Delta y)}{\partial y}\right]\Delta x\Delta z \tag{9.7.134}$$

Multiplying the right side by $\Delta y/\Delta y$ gives obviously:

$$\Delta F_x=\mu_d\left[\frac{\dfrac{\partial_x v_x(y+\Delta y)}{\partial y}-\dfrac{\partial_x v_x(y)}{\partial y}}{\Delta y}\right]\Delta x\Delta y\Delta z \tag{9.7.135}$$

The quantity in the square brackets should be recognized as the second derivative of $v_x(y)$ with respect to y. Dividing through both sides by the volume $\Delta x\Delta y\Delta z$ gives us the viscous force per unit volume:

$$f_{v_x}=\mu_d\frac{\partial^2 v_x(y)}{\partial y^2} \tag{9.7.136}$$

This is the formula for the viscous force per unit volume acting on the fluid particles when we have a purely x directed flow of a Newtonian fluid whose speed varies only in the y direction.

Now remember that we get earlier the law of viscous laminar flow:

$$v_x=\frac{\Delta P}{4\mu_d l}(R^2-r^2) \tag{9.7.137}$$

Applying the result we just get, this lead us to:

$$f_{v_x}=\mu_d\frac{\partial^2 v_x(r)}{\partial r^2}=\frac{\Delta P}{2l} \tag{9.7.138}$$

9.7.2.3 Bernoulli's Theorem

When we discuss of the motion of a fluid, the continuity equation (see section Thermodynamics page 3679), which expresses the conservation of mass (volume) of the fluid is an important concept.

$$\boxed{\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0} \tag{9.7.139}$$

Let us consider this equation in the particular case that interest us here: a non-viscous fluid in laminar flow moving inside a tube following parallel streams lines (the fluid motion is irrotational type - see section Vector Calculus page 1889), delimited by the surface A_1:

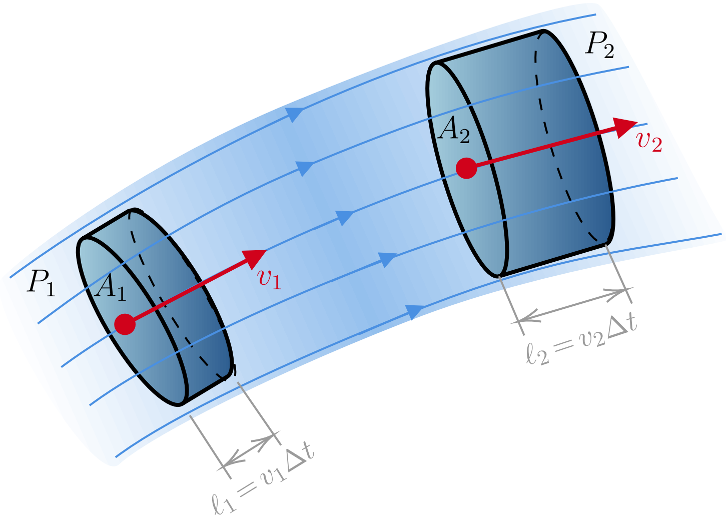

Figure 9.214: Non-viscous fluid in laminar flow from in a tube of parallel lines of current lines converging

We consider that we are in steady state (the appearance of movement is independent of time) and the mass is not provided by a source or removed by a well within the region. The volume of fluid which crosses A_1 in the interval corresponds Δt corresponds to a cylinder of base A_1, and length $v_1\Delta t$ and therefore volume of volume $A_1v_1\Delta t$. The mass of fluid which has passed through A_1 for the time Δt is therefore:

$$M_1 = \rho_1 A_1 v_1 \Delta t \tag{9.7.140}$$

And also:

$$M_2 = \rho_2 A_2 v_2 \Delta t \tag{9.7.141}$$

is the mass of fluid which has passed through A_2 during the same time interval. With the our assumptions, the mass conservation equation requires that two masses are the same, or expressed differently that:

$$\rho_1 A_1 v_1 \Delta t = \rho_2 A_2 v_2 \Delta t \tag{9.7.142}$$

Hence:

$$\boxed{\rho_1 A_1 v_1 = \rho_2 A_2 v_2} \tag{9.7.143}$$

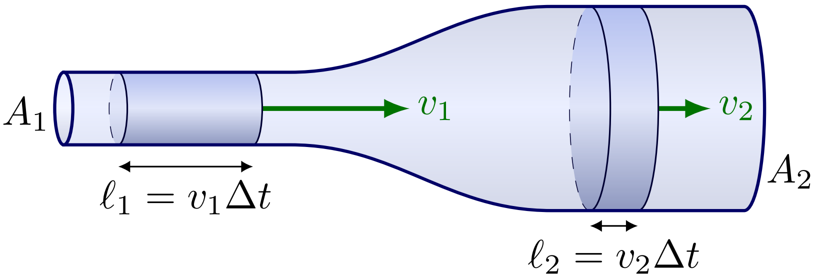

Figure 9.215: Bernoulli's theorem illustrated (author: Izaak Neutelings)

This is the shape of the continuity equation that interest us in our context. In addition, if the fluid is incompressible, the density is everywhere the same and the above relation reduces to:

$$A_1 v_1 = A_2 v_2 \tag{9.7.144}$$

Thus, the ratio of input/output speed in a tubular pipe will be usually (not included frictions!):

$$\frac{v_2}{v_1} = \frac{v_{\text{out}}}{v_{\text{in}}} = \frac{A_1}{A_2} = \frac{\pi R_1^2}{\pi R_2^2} = \frac{R_1^2}{R_2^2} = \frac{R_{\text{in}}^2}{R_{\text{out}}^2} \tag{9.7.145}$$

The continuity equation is indirectly known to all children and adults who play with or use a garden hose (thumb serves as a "convergent"):

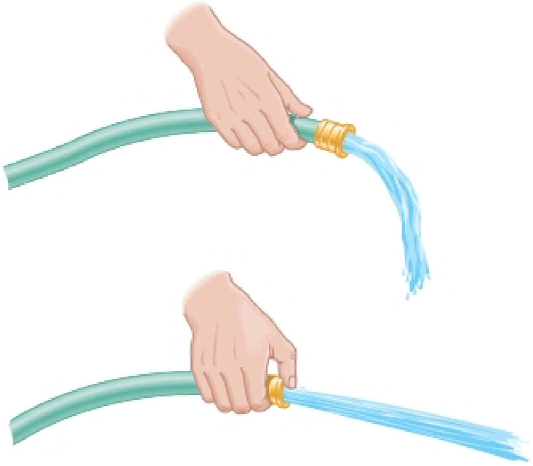

Figure 9.216: Application in everyday life of the continuity equation

Let us now consider a region in a fluid where there is a steady flow[31] as shown in the figure below:

---

[31] That is, the pressure, velocity, density, etc. can change from place to place, but they must not change as a function of time at any particular place (in your frame of reference).

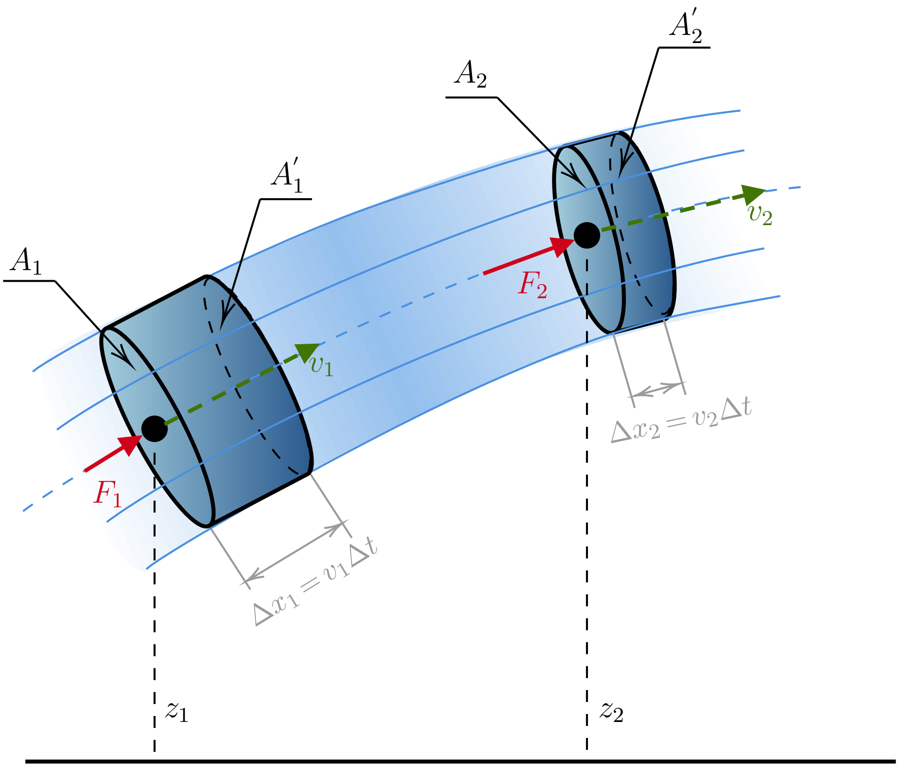

Figure 9.217: **Zoom of a fluid region for the Bernoulli's theorem**

During a short time interval Δt, the fluid which initially crossed the section A_1 has moved to a surface A'_1 at a distance $\Delta x_1 = v_1\Delta t$ while the fluid crossing the section A_2 is found on A'_2 at a distance $\Delta x_2 = v_2\Delta t$.

The both small cylinders have the same volume as the fluid is assumed to be incompressible and that the fluid passing through A_1 pushes the volume that pass through A_2 and therefore the equation continuity remains valid.

Given F_1 and F_2 the forces applied indirectly on the surface A_1 and A_2 due to the pressure prevailing in the fluid. Because of these forces, the fluid produce or receives work by moving the two volumes. In A_1, the surface is pushed by the fluid and the work performed on the fluid is $F_1\Delta x$ when on A_2 the fluid pushes the surface and the work done by the fluid is $F_2\Delta x$. The total work exerted on the fluid volume situated between A_1 and A_2 is therefore equal to:

$$W = F_1\Delta x_1 - F_2\Delta x_2 = P_1 A_1\Delta x_1 - P_2 A_2\Delta x_2 \tag{9.7.146}$$

where P_1 and P_2 are obviously the respective pressures on A_1 and A_2 and by writing obviously:

$$F = PA \tag{9.7.147}$$

according to the definition of the pressure. As:

$$A_1\Delta x_1 = A_2\Delta x_2 \tag{9.7.148}$$

according to the continuity equation and the assumption of incompressibility, we can write that:

$$W=(P_1-P_2)A_1\Delta x_1 \tag{9.7.149}$$

The external work applied on the system changes its internal energy as established in the section Thermodynamics ($W=\Delta U$). For the considered volume of fluid, the internal energy of the volumes highlighted in the figure above includes kinetic energy and gravitational energy. The fluid between A_1 and A_2 gains energy in the volume $A_2\Delta x_2$. Suppose the two volumes have equal mass m, again because of the continuity equation. Then the net energy gain is:

$$\Delta U=U_2-U_1=\left(\frac{1}{2}mv_2^2+mgz_2\right)-\left(\frac{1}{2}mv_1^2+mgz_1\right) \tag{9.7.150}$$

Since we have already assumed the fluid as incompressible, the density ρ is the same everywhere and m can be replaced by $\rho A_1\Delta x_1$ at both ends. Hence:

$$\Delta U=\left[\left(\frac{1}{2}\rho v_2^2+\rho g z_2\right)-\left(\frac{1}{2}\rho v_1^2+\rho g z_1\right)\right]A_1\Delta x_1 \tag{9.7.151}$$

Combining this relation with $W=(P_1-P_2)A_1\Delta x_1$ we get:

$$P_1-P_2=\left(\frac{1}{2}\rho v_2^2+\rho g z_2\right)-\left(\frac{1}{2}\rho v_1^2+\rho g z_1\right) \tag{9.7.152}$$

or:

$$\boxed{\frac{1}{2}\rho v_1^2+\rho g z_1+P_1=\frac{1}{2}\rho v_2^2+\rho g z_2+P_2} \tag{9.7.153}$$

As the above equation relates the magnitudes taken between two arbitrary points along a streamline, we can generalize and write:

$$\boxed{\frac{1}{2}\rho v^2+\rho g z+P=c^{te}} \tag{9.7.154}$$

This result, known as the "Bernoulli's theorem", expresses the constancy of the pressure along a streamline in an incompressible fluid, irrotational and non-viscous and where external volumetric forces are derived from a potential energy (we'll come back on this more in detail after having determined the Navier-Stokes equations). The above relation can also obviously be interpreted as saying the enthalpy of the parcel remains constant as it flows along a streamline.

We will see further below during our study of gas the generalized version of the above expression involving the polytropic constant γ (heat capacity ratio).

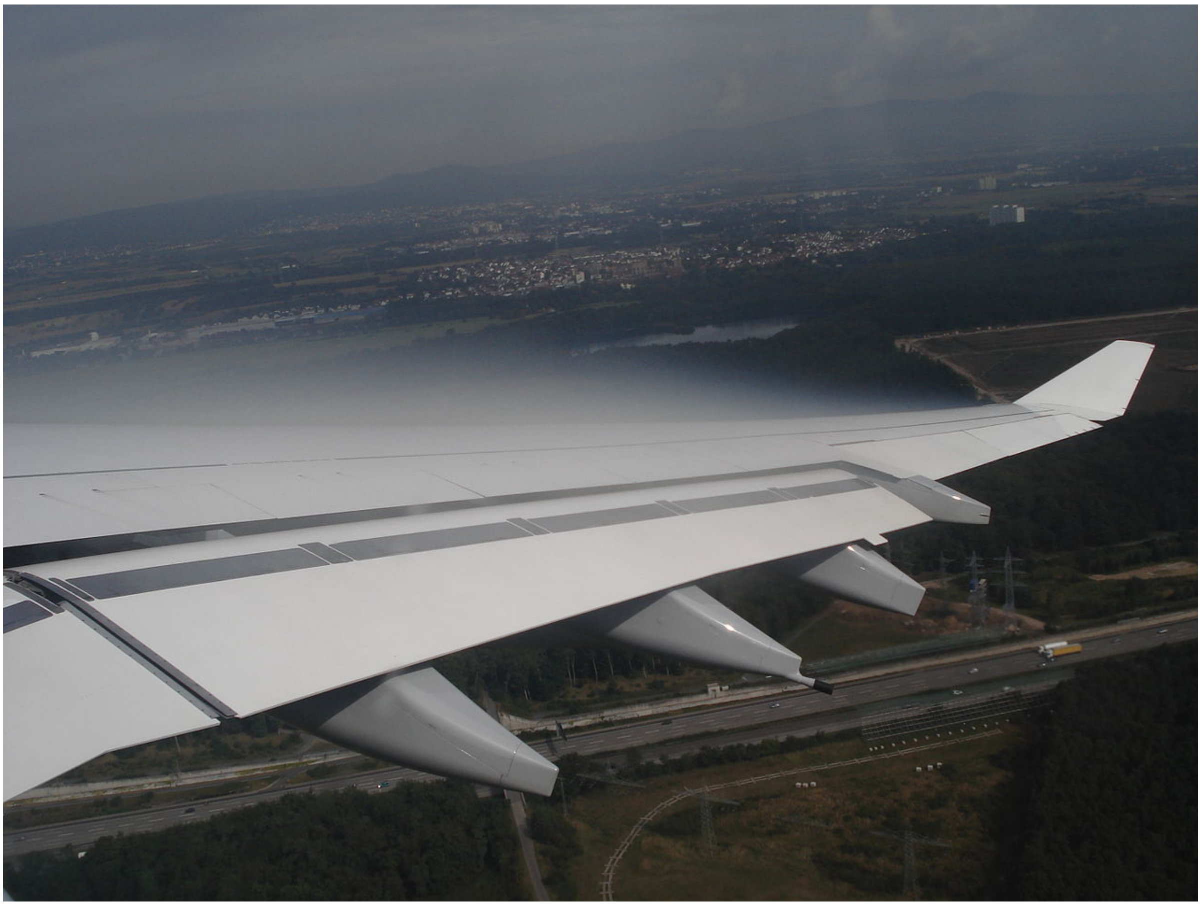

Figure 9.218: **Condensation visible over the upper surface of an Airbus A340 wing caused by the fall in temperature accompanying the fall in pressure, both due to acceleration of the air (source: Wikipedia)**

The conservation of the left quantity expresses the conservation of energy along a stream line and we find respectively the volumetric kinetic energy, the gravitational volumetric potential energy and the pressure.

Remark

Form a stream line to the other, that is the value of the constant c^{te} that change. In addition, use of Bernoulli's theorem requires to know (or at least to have an idea) of the shape of the stream line.

The reader must keep in mind that the following assumptions must be met for this Bernoulli equation to apply:

- the flow must be steady, i.e. the fluid velocity at a point cannot change with time
- the flow must be incompressible - even though pressure varies, the density must remain constant along a streamline
- friction by viscous forces has to be negligible (no thermic dissipation)

Let us notice also an another elegant and easy way to find this relation. Indeed, the conservation of energy gives us along a stream line:

$$E_c+E_p+E_P=c^{te} \tag{9.7.155}$$

with respectively the kinetic energy E_c, the potential energy E_p and the pressure energy E_P (that latter is not intuitive). Hence:

$$\frac{1}{2}mv^2+mgz+Fd=c^{te} \tag{9.7.156}$$

and if we divide all by the volume, Then We get:

$$\frac{1}{2}\rho v^2+\rho gz+P=c^{te} \tag{9.7.157}$$

that's it... Therefore Bernoulli equation is simply a statement of the principle of conservation of energy in fluids!

The term:

$$q=\frac{1}{2}\rho v^2 \tag{9.7.158}$$

is quite famous and named "dynamic pressure". It is especially famous to rocket science lovers that know the famous "Max q". The max q condition is the point when an aerospace vehicle's atmospheric flight reaches maximum dynamic pressure.

Now consider now two important applications of Bernoulli's theorem.

If the fluid moves in a horizontal plane, the gravitational potential energy remains constant and then the Bernoulli equation reduces then to (or also in absence of gravitational field):

$$\boxed{\frac{1}{2}\rho v^2+P=\frac{1}{2}\rho\left(\frac{\mathrm{d}x}{\mathrm{d}x}\right)^2+P=c^{te}} \tag{9.7.159}$$

Thus, in a closed horizontal pipe (wind tunnel), the velocity increase as the pressure decrease and vice versa. We also use this effect to participate in the thrust of an airplane at least in the case of wind tunnel tests in a closed cylinder (caution! this parameter is minor in the case of a displacement in the atmosphere which is an open volume , because it is not what contributes the most to the flight of an airplane, it is the Magnus effect whose proof is given in the Aerospace section).

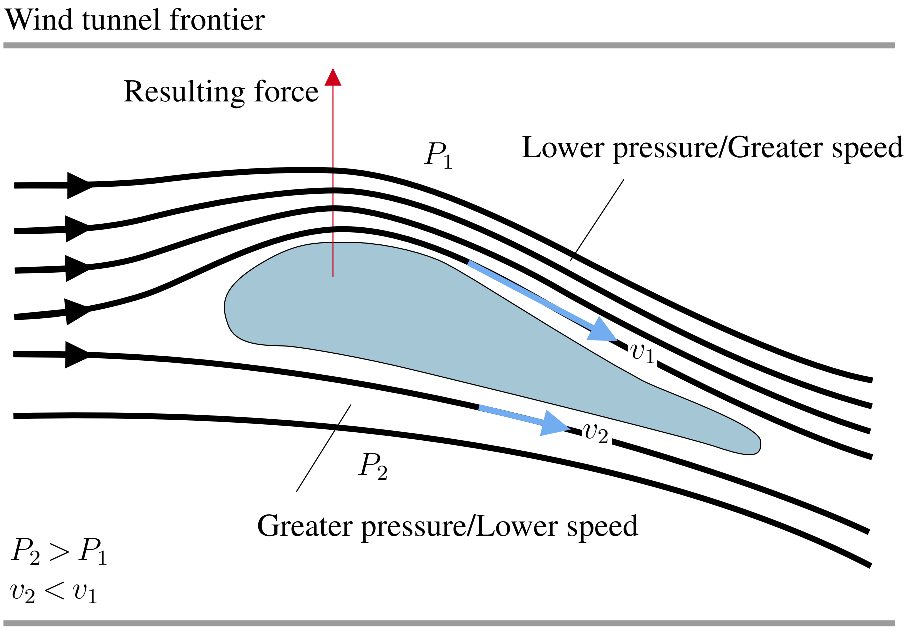

Figure 9.219: Illustration of the profile of a wing with the corresponding pressures and speeds in a wind tunnel

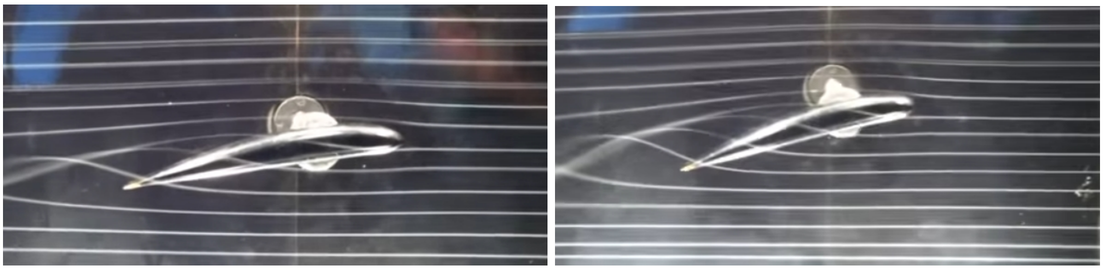
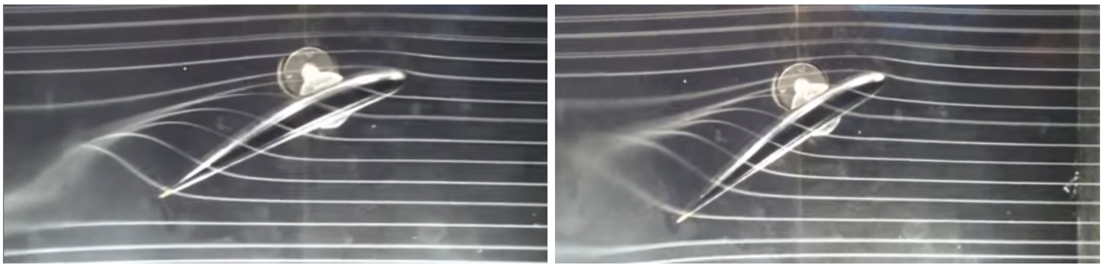
The profile of a wing is most of time constructed in such a way that the air has can in some given configuration of the wind greater velocity above the wing surface than under it, producing a higher pressure below that of the wing, Above in the case of an air flow in a closed cylinder (as was the case in the first wind tunnel tests in the early 1900s according to holocene calendar!). This results in a resultant upward force (but it's not the only force from which the lift origins!).

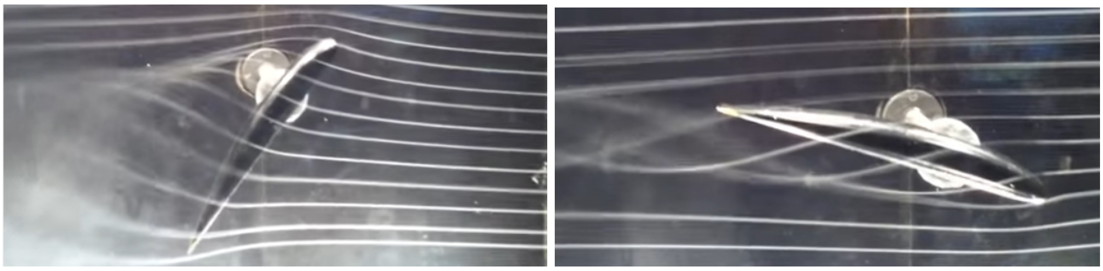
In other words, a specialist in aerodynamics (for aircraft) or in hydrodynamics (for roll stabilizers of large boats) would say in the case of closed volume tests:

- At the "extrados": By curvature effect, the air (water) particles will pass through a smaller transverse surface in the test cylinder and by Venturi effect will then accelerate. Their velocity will therefore first increase strongly and then diminish in order to find at the trailing edge the initial velocity of the flow. All the extrados is therefore the seat of a generalized local depression.
- In the "intrados": By curvature, the air (water) particles will pass through a larger transverse surface in the test cylinder and by Venturi effect will then decelerate. Their velocity will therefore decrease strongly and then increase in order to recover the initial velocity of the flow. All the intrados is therefore the center of a generalized local overpressure.

The lift of a wing with regard to its geometry is due in part to the depression on the extrados, not to the overpressure on the intrados. The wing does not mainly "rest" on the air, but is sucked upward little bit by the latter (for more details see the Aerospace section)!







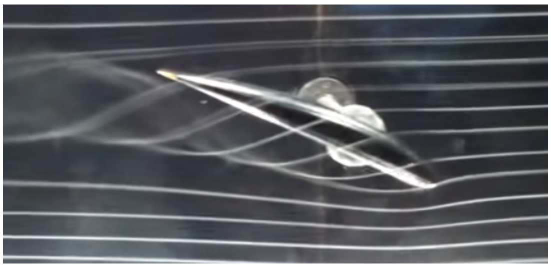


Figure 9.223: **Wing streamlines in wind tunnel in real life**

Another thing, if the fluid is not in motion, we have then Bernoulli equation which is obviously written:

$$\boxed{\rho g z + P = c^{te}} \quad (9.7.160)$$

and that is sometimes named the "Laplace hydrostatic equation" (used in communicating vessels study).

9.7.2.3.1 Torricelli's barometer

Take a glass tube about one meter long opened at one end having uniform diameter. Fill the whole tube with pure mercury. Close the open end of the tube tightly with finger and invert the tube. Take this inverted end of the tube along with your finger inside the pure mercury contained in a container. Now remove the finger and take necessary steps to keep the tube vertical. It will be observed that the mercury has come down to some extent and has attained a steady position. It might appear apparently that the mercury inside the tube is in standing position by itself. But in reality it is not so. It happens so due to air pressure.

The force of gravity on air is directed downward. The force of gravity on the mercury in the bowl and the tube is directed downward. Newton's third law: For every force, there is an equal and opposite force. The mercury in the tube drops down until it is balanced by the force exerted by air on the mercury in the bowl.

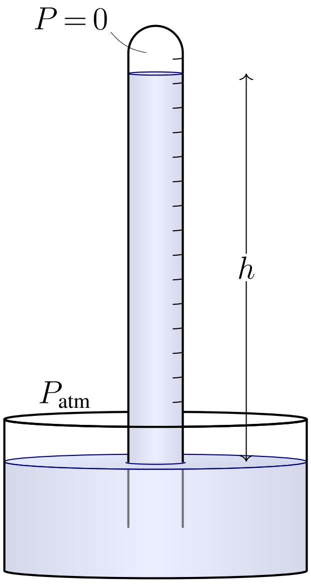

Figure 9.224: **Torricelli's experiment (author: Izaak Neutelings)**

The space that remains just above the mercury column in the tube up to its closed end is totally empty. This empty space (assumed as because we will see during study of Quantum Field Theory that there are not such things as "empty space") is termed as "Torricelli's vacuum" (because in reality it's not a vacuum as it contains mercury vapor).

Atmosphere is always exerting pressure on the mercury of the container. This pressure is convoyed through the mercury and acts in the upward direction in the tube. This very pressure holds the mercury column of the tube. In absence of this pressure the mercury of the tube will come down due to the force of gravity. Therefore, atmospheric pressure is equal to the pressure of the mercury column of the tube. Generally the height of the mercury column that remains in the tube in about 76 [cm] i.e the air pressure supports the pressure of 76 [cm] column of mercury. In this way using the height of a liquid the atmospheric pressure can be measured.

We can determine the 76 [cm] theoretically using the relation derived earlier as the vacuum on the top of the tube exerts an equal force to that of the pressure of the surrounding of the atmosphere. That means:

$$P_{\text{atm}}=P_{\text{Hg}} \qquad (9.7.161)$$

As derived earlier above we know that we have:

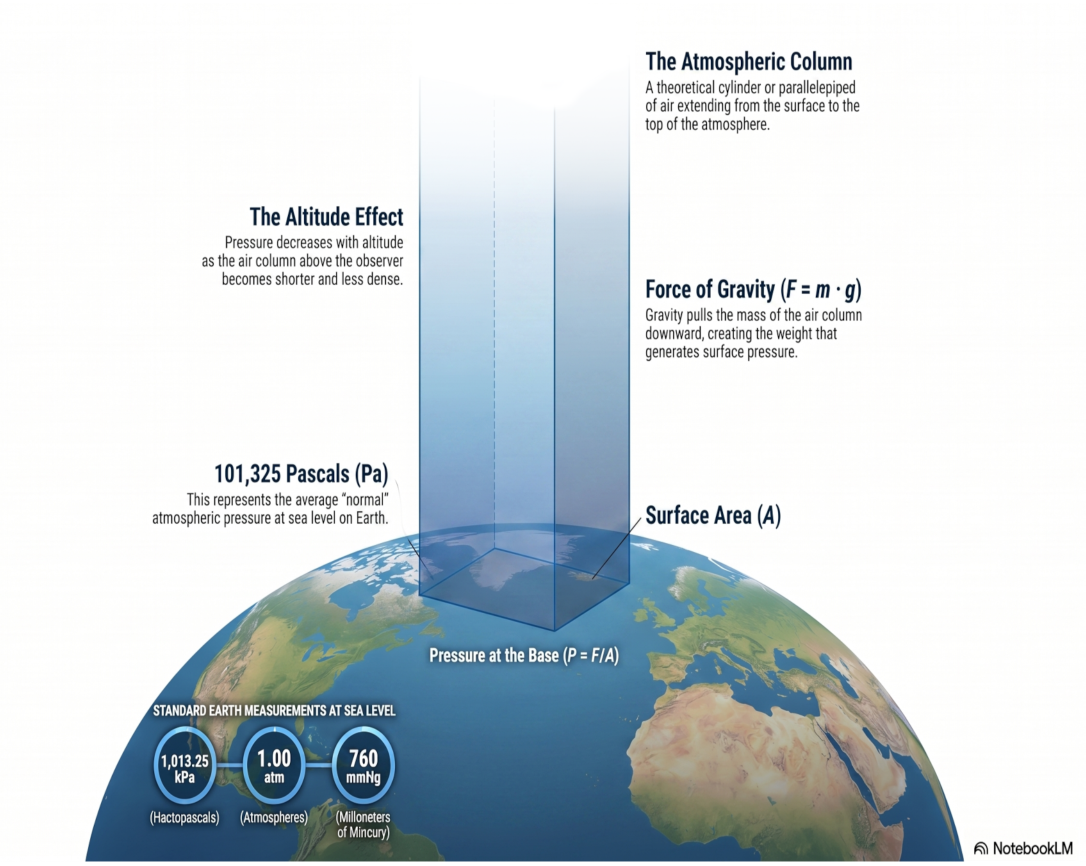
$$P_{\text{Hg}}=\rho_{\text{Hg}}gh \qquad (9.7.162)$$

Hence:

$$P_{\text{atm}}=P_{\text{Hg}}=\rho_{\text{Hg}}gh \qquad (9.7.163)$$

Therefore using the standard pressure and temperature at sea level and mercury density at standard pressure and temperature and average gravity value on Earth we get:

$$h=\frac{P_{\text{atm}}}{\rho_{\text{Hg}}g}\cong\frac{101,325}{13,545.848\cdot 9.80665}\cong 0.762\,[\text{m}]\cong 76\,[\text{cm}] \qquad (9.7.164)$$



The Atmospheric Column
A theoretical cylinder or parallelepiped of air extending from the surface to the top of the atmosphere.
The Altitude Effect
Pressure decreases with altitude as the air column above the observer becomes shorter and less dense.
Force of Gravity (F = m · g)
Gravity pulls the mass of the air column downward, creating the weight that generates surface pressure.
101,325 Pascals (Pa)
This represents the average "normal" atmospheric pressure at sea level on Earth.
Surface Area (A)
Pressure at the Base (P = F/A)

9.7.2.3.2 Torricelli's law

The "Torricelli's law", also known as "Torricelli's theorem", is a theorem in fluid dynamics relating the speed of fluid flowing out of an opening to the height of fluid above the opening assuming no air resistance, viscosity, or other hindrance to the fluid flow. This is a classic case study in high schools.

For this study let us consider a closed volume (recipient) containing a liquid of equal density ρ and having small orifice of surface S_2 from which the liquid flows outwards. We want to determine the speed v_2 at which the liquid flow of this orifice:

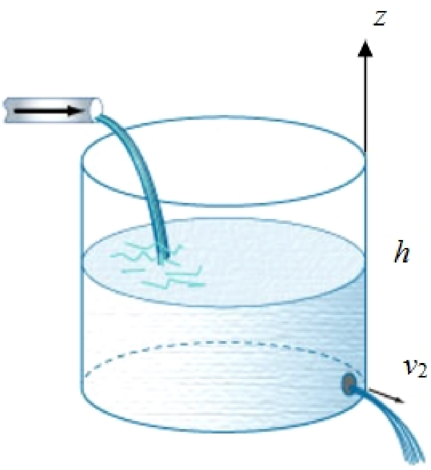

Figure 9.225: **Torricelli experiments configuration**

The volume is assumed to be big enough that neither the liquid level nor the pressure P above its surface S_1 will appreciably vary during the flow. Since the liquid exhausting virtual tube runs from the region of the surface of the liquid to the open orifice in the open air, we have:

$$P_1 = P \tag{9.7.165}$$

A liquid flowing in the open air is at atmospheric pressure, $P_2 = P_A$, because the liquid is surrounded by free air and nothing is present to maintain a pressure difference. According to Bernoulli's theorem, with:

$$z_1 - z_2 = h \tag{9.7.166}$$

we have therefore found a current line (streamline) and we can write:

$$P + \frac{1}{2}\rho v_1^2 + \rho g h = P_A + \frac{1}{2}\rho v_2^2 \tag{9.7.167}$$

hence:

$$v_2^2 = v_1^2 + \frac{2(P - P_A)}{\rho} + 2gh \tag{9.7.168}$$

From the continuity equation principle (flow conservation):

$$v_1 S_1 = v_2 S_2 \tag{9.7.169}$$

we deduce that if $S_1 \gg S_2$ then $v_2 \gg v_1$ and v_1^2 is then negligible relatively to v_2^2. In the particular but frequent case where the recipient is open to the open air ($P = P_A$), the pressure energy density disappears. The fluid flows only under the effect of gravity, without being pushed by a difference in pressure. We then find (by multiplying this result by the surface of the orifice, we get the flow rate):

$$\boxed{v_2 = \sqrt{2gh}} \tag{9.7.170}$$

which is independent of the sections! Obviously by using this last relation, in the case where the flow and the surface of the orifice are given, we can deduce the flow velocity in $\mathrm{m}^2 \cdot \mathrm{s}^{-1}$.

This relation constitutes the "Torricelli theorem". Curiously, we have already seen this relation in the section of Classical Mechanics for the rate of free fall of a body (see page 3435). Therefore it comes the observation made by Torricelli: if the jet is directed directly upwards, it almost reaches the level of the surface of the liquid in the volume. The reason why the jet would not actually reach this level is because some energy loss due to friction.

From this result we can study an interesting case in practice and often also used in numerical modelling courses. It is the exercise consisting in determining the time for a tank (recipient) of the following type to empty:

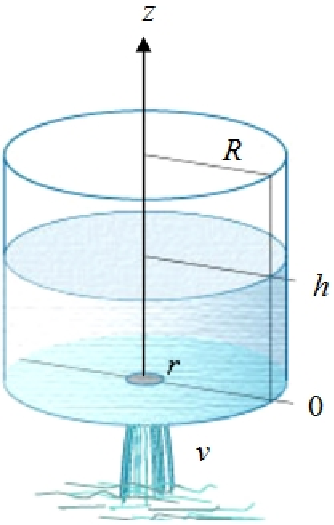

Figure 9.226: **Tank emptying**

We start from the theorem of Torricelli in the case where the orifice is much smaller than the diameter of the tank (we will see after that if not the speed is not the same!):

$$v=\sqrt{2gz} \tag{9.7.171}$$

And if we denoted the flow rate by D then we have trivially:

$$D=-\pi r^2\sqrt{2gz} \tag{9.7.172}$$

where the sign "$-$" is there to indicate that the tank is emptying. We also have the flow rate which is defined by:

$$D=\frac{\mathrm{d}V}{\mathrm{d}t} \tag{9.7.173}$$

and the variation of volume V in the tank be expressed as:

$$\mathrm{d}V=S(z)\mathrm{d}z \tag{9.7.174}$$

We then have explicitly:

$$\frac{S(z)\mathrm{d}z}{\mathrm{d}t}=D(z)=-\pi r^2\sqrt{2gz} \tag{9.7.175}$$

In our particular case, the surface does not depend on the z. We have then:

$$\frac{\mathrm{d}z}{\mathrm{d}t}=-\frac{\pi r^2}{S(z)}\sqrt{2gz}=-\frac{\pi r^2}{\pi R^2}\sqrt{2gz}=-\frac{r^2}{R^2}\sqrt{2gz} \quad (9.7.176)$$

Either after rearrangement:

$$\frac{\mathrm{d}z}{\sqrt{z}}=-\frac{r^2}{R^2}\sqrt{2g}\mathrm{d}t \quad (9.7.177)$$

Now we integrate on the left of H to 0 (H being the initial height of the fluid) and on the right from the time 0 to T. We then have:

$$\int_H^0 \frac{\mathrm{d}z}{\sqrt{z}}=-\int_0^T \frac{r^2}{R^2}\sqrt{2g}\mathrm{d}t \quad (9.7.178)$$

Either after rearrangement we deduce that the time T of emptying is:

$$\boxed{T=\frac{R^2}{r^2}\sqrt{\frac{2H}{g}}} \quad (9.7.179)$$

This formula can be used to calibrate a water clock.

And we notice that if the radius of the orifice of evacuation is equal to the radius of the cylinder we fall back on the expression of the free fall time of a point mass as proved in the section of Classical Mechanics:

$$T=\sqrt{\frac{2H}{g}} \quad (9.7.180)$$

The figure below show set of Torricelli jets, vertically aligned, leaving the reservoir horizontally:

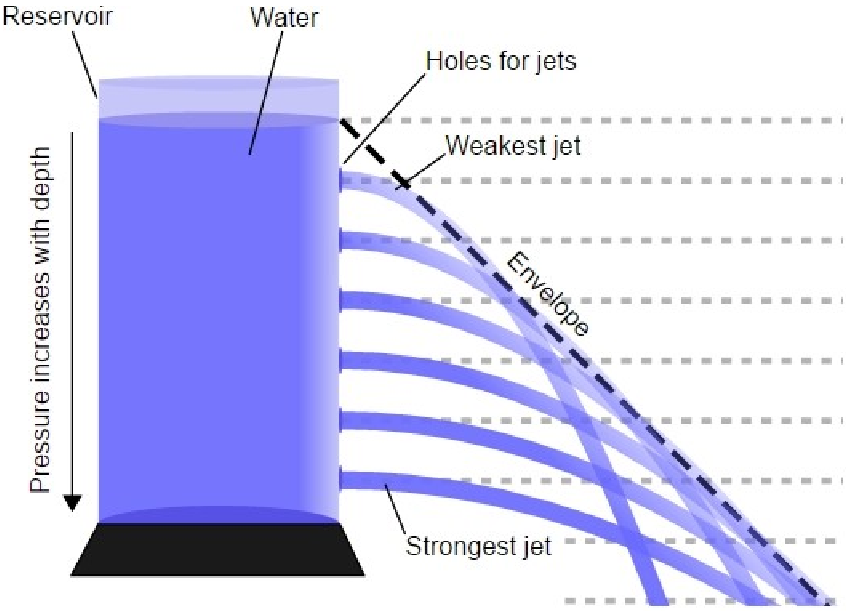

Figure 9.227: **Torricelli jets envelope illustration (source: Wikipedia, author: Matt Cook)**

In this case, the jets have an envelope (a concept also due to Torricelli) which is a line descending at $45°$ from the water's surface over the jets. Each jet reaches farther than any other jet at the point where it touches the envelope, which is at twice the depth of the jet's source. The depth at which two jets cross is the sum of their source depths. Every jet (even if not leaving horizontally) takes a parabolic path whose directrix is the surface of the water.

Remark

Some Abrahamic religions believe that there was a flood on the whole Earth that covered all mountains (including therefore Mt Everest at $8,849$ [m]) thanks to a rain falling during 40 days according to their myths and legends. How fast would the rain have to fall to make $8,849$ [m] in 40 days? That's easy! Forty days times 24 hours per day is 960 hours. Dividing $8,849$ by 960 and we find a rainfall of about 9 meters per hours! On a surface of $1\,[\text{m}^2]$ that represents a volume of $9,000\,[\text{L}\cdot\text{h}^{-1}]$, or $150\,[\text{L}\cdot\text{min}^{-1}]$, or $2.5\,[\text{L}\cdot\text{s}^{-1}]$. Practice shows that a debit rate between $0.5\,[\text{L}\cdot\text{min}^{-1}]$ and $60\,[\text{L}\cdot\text{min}^{-1}]$ per square meter is enough to cut the strongest wood. So if the Arch was made of wood it was cut to pieces by the rain...

We don't even need to say that according to the same abrahamic myths and legends that the roughly $4,500,000,000$ cubic kilometre of water - a cube of about $1,650$ [km] side - receded in 150 days naturally is simply impossible.

9.7.2.3.3 Siphon

A "siphon" is any of a wide variety of devices that involve the flow of liquids through tubes. In a narrower sense, the word refers particularly to a tube in an inverted "U" shape, which causes a liquid to flow upward, above the surface of a reservoir, with no pump, but powered by the fall of the liquid as it flows down the tube under the pull of gravity[32], then discharging at a level lower than the surface of the reservoir from which it came.

There are two leading theories about how siphons cause liquid to flow uphill, against gravity, without being pumped, and powered only by gravity. The traditional theory for centuries was that gravity pulling the liquid down on the exit side of the siphon resulted in reduced pressure at the top of the siphon. Then atmospheric pressure was able to push the liquid from the upper reservoir, up into the reduced pressure at the top of the siphon, like in a barometer or drinking straw, and then over. However, it has been demonstrated that siphons can operate in a vacuum and to heights exceeding the barometric height of the liquid. Consequently, the cohesion tension theory of siphon operation has been advocated, where the liquid is pulled over the siphon in a way similar to the chain fountain. It need not be one theory or the other that is correct, but rather both theories may be correct in different circumstances of ambient pressure. The atmospheric pressure with gravity theory cannot explain siphons in vacuum, where there is no significant atmospheric pressure. But the cohesion tension with gravity theory cannot explain CO_2 gas siphons, siphons working despite bubbles, and the flying droplet siphon, where gases do not exert significant pulling forces, and liquids not in contact cannot exert a cohesive tension force.

All known published theories in modern times recognize Bernoulli's equation as a decent approximation to idealized, friction-free siphon operation. And this is what we will study here considering the following configuration:

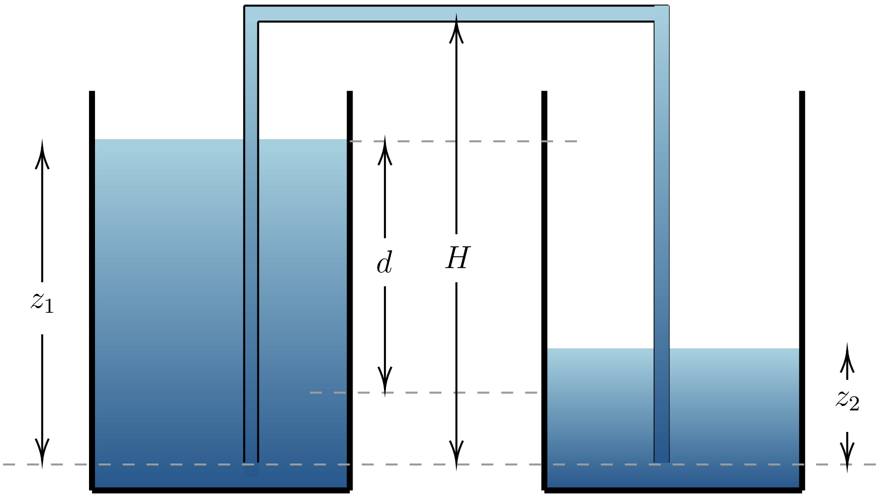

Figure 9.228: **Special case of siphon**

Let us consider that the figure above is a snapshot of an observation and the we see the fluids flows from left to right.

The first thing we want to do is to find the velocity v of the fluid in the tube.

---

[32] Keep in mind that's in the framework of the Newtonian model of gravity as we that in General Relativity there are no "pull".

Begin by applying Bernoulli's theorem to the top of the fluid in the left container and to the bottom right hand side of the tube. The pressure at the bottom left is just $P_0 + \rho g z_2$, so at the point where fluid is entering the second tank:

$$P_0 + \rho g z_1 + \frac{1}{2}\rho v_1^2 = P_0 + \rho g z_2 + \frac{1}{2}\rho v^2 \tag{9.7.181}$$

and (solving for v, cancel P_0, assume $v_1 \ll v$, reorganize and):

$$\frac{1}{2}\rho v^2 = \rho g \left(z_1 - z_2\right) \rightarrow v \cong \sqrt{2gd} \tag{9.7.182}$$

which solves the question.

Now let us found the pressure at the top of the tube.

To find the pressure P_H at the top of the tube (at height H) we have to apply Bernoulli's theorem to the top of the left container (again) but also to the fluid in the tube at height H :

$$P_0 + \rho g z_1 + \frac{1}{2}\rho v_1^2 = P_H + \rho g H + \frac{1}{2}\rho v^2 \tag{9.7.183}$$

Rearranging and using the fact that $\frac{1}{2}\rho v^2 = \rho g \left(z_1 - z_2\right)$ and still assuming $v_1 \ll v$:

$$\begin{aligned} P_H &\cong P_0 - \rho g H + \rho g z_1 - \frac{1}{2}\rho v^2 \\ &\cong P_0 - \rho g H + \rho g z_1 - \rho g \left(z_1 - z_2\right) \\ &\cong P_0 - \rho g H + \rho g z_2 = P_0 - \rho g \left(H - z_2\right) \end{aligned} \tag{9.7.184}$$

One interesting (and correct!) consequence of this is that there is a limit to the height over which one can siphon a fluid. The pressure in the tube cannot be negative, as (before) it reaches 0 (a vacuum) the fluid will chemically "come apart" and fall down the two columns as air pressure no longer suffices to hold it up in the tube and the picture will become that of two barometers with a shared vacuum space. We see that:

$$P_{\text{min}} \approx 0 = P_0 - \rho g \left(H_{\text{max}} - z_2\right) \tag{9.7.185}$$

or when the difference of H and z_2 (the height of fluid in the lower of the two vessels) is equal to $P_0/\rho g$ (about 10 meters for water) the siphon will break.

9.7.2.3.4 Communicating vessels

Let's talk a little bit about the communicating vessels because like this it seems to be nothing quite interesting but... still in this beginning of the 121st century (holocene calendar), most buildings have a supply of running water based on this principle (reserve lakes in height, Water castles and so on...) and many people have used the principle of communicating vessels to siphon a fluid from one tank / container to another at least once in their lives.

We can first introduce the concept intuitively based on the experimental observation of the 4 communicating vessels of the following figure with a non-viscous fluid:

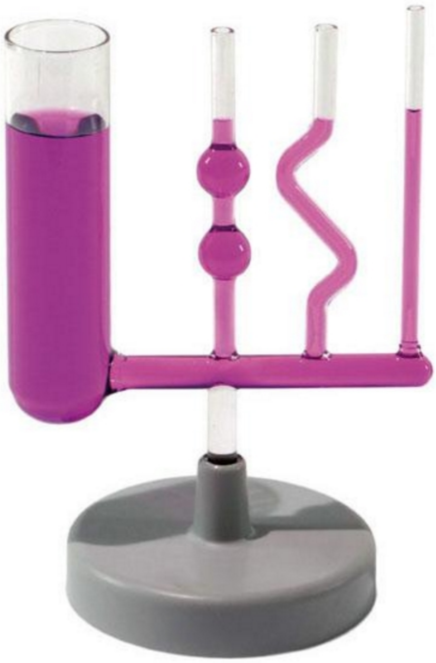

Figure 9.229: Photo of the principle of communicating vessels

we see that the fluid stabilizes at the same height for the four vessels independently of heir shape!

The equilibrium of vessel is explained be the development that follows!

Let us recall that we have by definition:

$$P=\frac{F}{S} \tag{9.7.186}$$

and therefore:

$$\mathrm{d}\vec{F}=-P\mathrm{d}\vec{S} \tag{9.7.187}$$

Using the gradient theorem proved in the section of Vector Calculus, we have:

$$\vec{F}=\oiint_S -p\mathrm{d}\vec{S}=\iiint_V \vec{\nabla}(-p)\mathrm{d}V=\iiint_V -\vec{\nabla}p\mathrm{d}V \tag{9.7.188}$$

In a volume of fluid in an homogeneous gravitational field we have:

$$\vec{F}=\iiint_V \vec{g}\mathrm{d}m=\iiint_V \rho\vec{g}\mathrm{d}V=\vec{g}\iiint_V \rho\mathrm{d}V=\vec{g}m \tag{9.7.189}$$

Therefore putting the two previous triple integrals:

$$\vec{F}=\iiint_V -\vec{\nabla}p\mathrm{d}V \qquad \text{and} \qquad \vec{F}=\iiint_V \rho\vec{g}\mathrm{d}V \tag{9.7.190}$$

together we identify the "hydrostatic balance":

$$-\vec{\nabla}p=\rho\vec{g} \tag{9.7.191}$$

In one dimension that can be rewritten:

$$\mathrm{d}p=-\rho g\mathrm{d}z \tag{9.7.192}$$

That is:

$$\boxed{P=P_0+\rho g(z-z_0)=P_0+\rho gh} \tag{9.7.193}$$

That is the "fundamental theorem of hydrostatics" or sometimes also named "Stevin's law" (or "Pascal-Stevin law"): the pressure at a point in a liquid in statics equilibrium depends only on the depth at that point! This is a quite counter-intuitive result form some people and that's why it is also named the "hydrostatic paradox" in some countries.

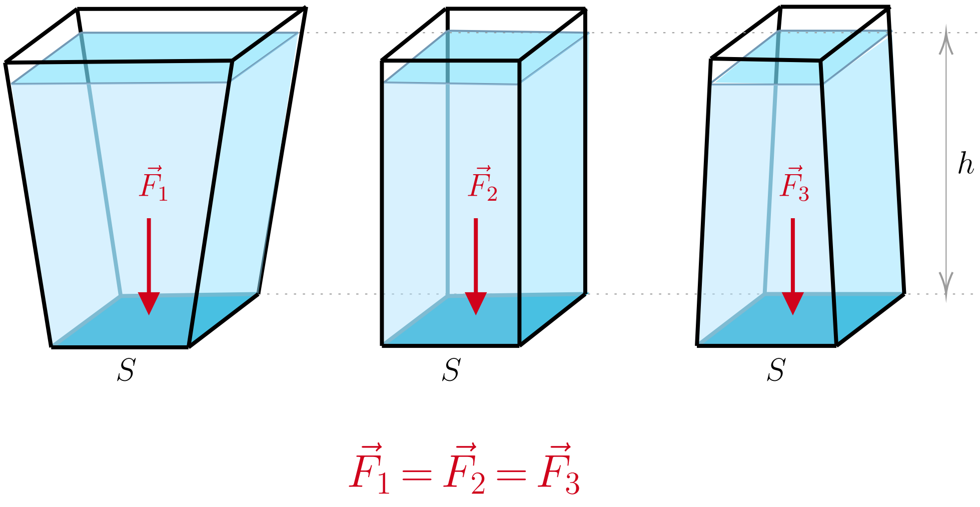

Figure 9.230: **Hydrostatic paradox illustrated**

Obviously the relation above on Earth is often denoted:

$$P=P_{\text{atm}}+\rho gh \tag{9.7.194}$$

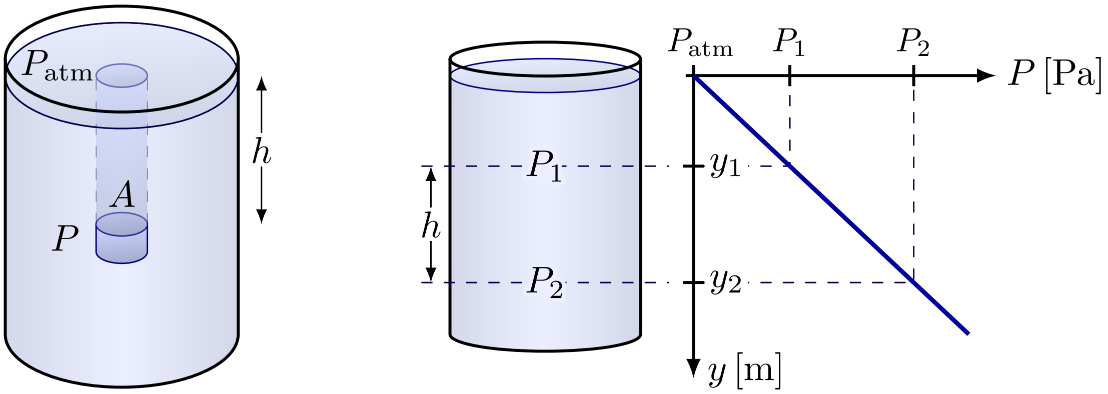

Figure 9.231: **Fundamental theorem of hydrostatics illustrated (author: Izaak Neutelings)**

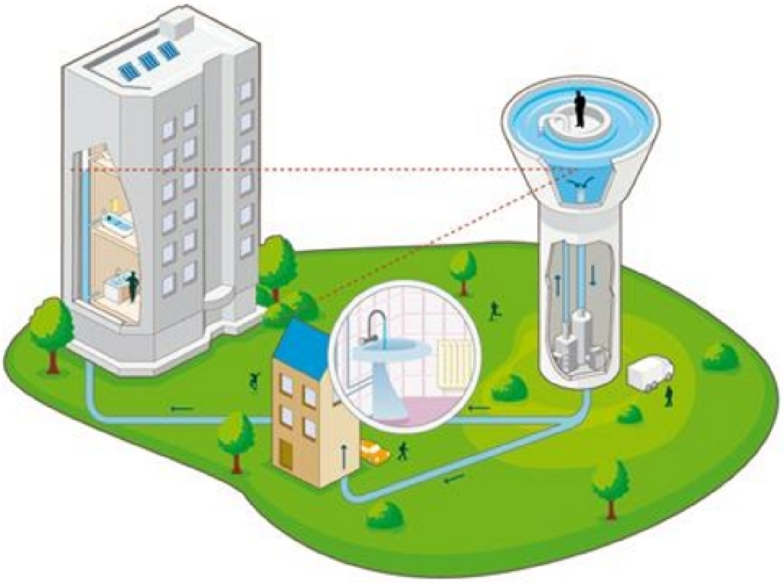
Remark

We will prove far far far further below that we fall back on this relation from the Navier-Stokes equation!

The same theorems applies for a water tower (essential if it is to reduce the costs of supply and if the location does not allow to play with the topography of the places):



© AGENCE RESEAUX - Illustration :Kler Roger - 2009

Figure 9.232: **Application of communicating vessels with water towers**

So if we want for example on the 4th floor of a building to have a minimum flow at a given tap, we will have to apply Torricelli's theorem to know how many meters h above the tap level we must found the water level in a water tower.

We had obtained earlier above:

$$v=\sqrt{2gh} \tag{9.7.195}$$

Therefore:

$$h=\frac{v^2}{2g} \tag{9.7.196}$$

Either by using the flow definition:

$$h=\frac{\left(\dfrac{D}{S}\right)^2}{2g} \tag{9.7.197}$$

Where D is the flow rate to be supplied in cubic meters per second and S is the cross-section through which we must ensure the same flow! Thus, a flow rate of 0.05 litres per second (typical of a kitchen or bathroom tap), that is to say $5\cdot 10^{-5}\;[\mathrm{m}^3\cdot\mathrm{s}^{-1}]$, through a section having a radius of 0.5 centimetres will give:

$$h=\frac{\left(\dfrac{0.05\cdot 10^{-3}}{\pi 0.005^2}\right)^2}{2\cdot 9.81}\cong 2\;[\mathrm{m}] \tag{9.7.198}$$

This value that gives the minimum height difference between the water tower water level and the 4th floor where is our tap of interest obviously does not take into account the pressure drop in the pipe!

9.7.2.3.5 Venturi effect

Some practical applications of fluid mechanics result from the interdependence of pressure and velocity and there is a category of situations in which the potential gravitational energy variation is negligible. The Bernoulli equation then connects the pressure difference to the kinetic energy difference and therefore the variation of the square of the velocity.

To introduce the Venturi effect let us consider an incompressible (!) fluid, non-viscous and of density ρ. The fluid flows in steady state in a cylindrical pipe of radius R_1 and cross section S_1 followed by a cylindrical tube of radius R_2 and cross section S_2 and which then takes back the initial geometry of radius R_1 and of section S_1 (it is typically connection which it is customary to name "Venturi tube"). The connection is made by a long cylindrical pipe so that we stay in laminar regime:

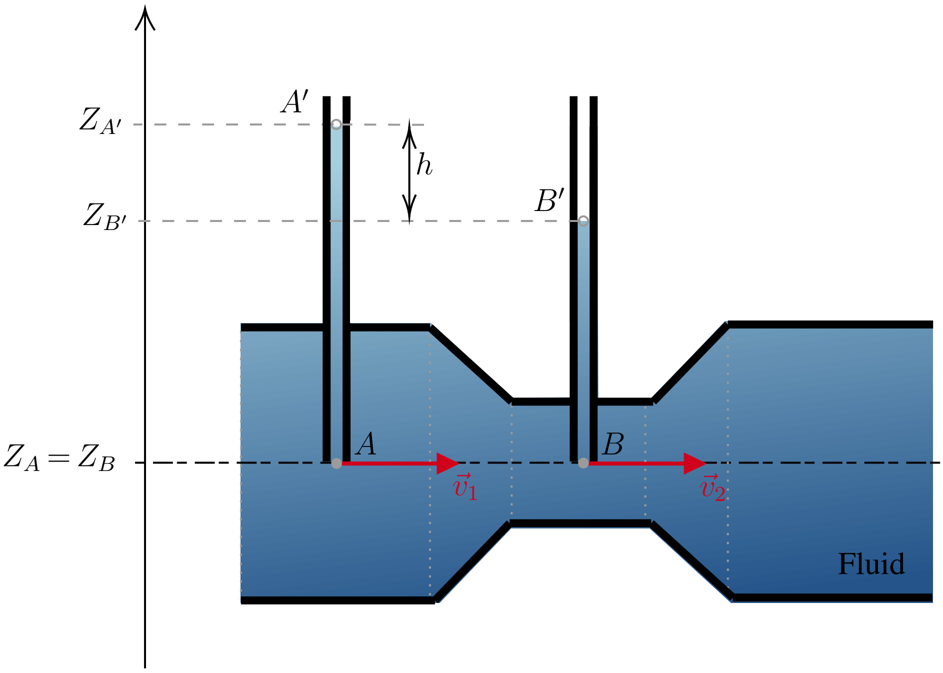


Figure 9.233: Venturi tube configuration study

We know (continuity equation) that:

$$S_1 v_1 = S_2 v_2 \tag{9.7.199}$$

Which means, as we have seen it already, that a diminution of the section through which the fluid passes, results in an increase of its velocity.

In any situation where the incoming flux is about the same level as the decreasing radius we have $Z_a \cong Z_B$ and then the Bernoulli's equation:

$$P_1 + \frac{1}{2}\rho v_1^2 + \rho g Z_A = P_2 + \frac{1}{2}\rho v_2^2 + \rho g Z_B \tag{9.7.200}$$

becomes:

$$P_1 + \frac{1}{2}\rho v_1^2 = P_2 + \frac{1}{2}\rho v_2^2 \tag{9.7.201}$$

Using the equation of continuity, to eliminate (arbitrarily) v_1, we get after rearranging:

$$\boxed{P_1 - P_2 = \frac{1}{2}\rho v_2^2 \left(1 - \frac{S_2^2}{S_1^2}\right)} \tag{9.7.202}$$

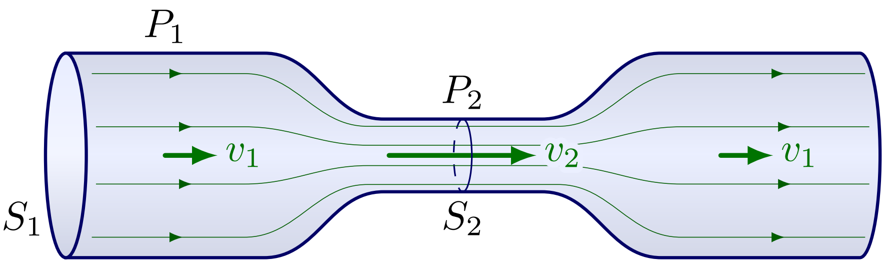

Figure 9.234: Venturi effect illustrated (author: Izaak Neutelings)

We can also write using the fundamental equation of hydrostatic proven just earlier above:

$$P_1 - P_2 = \rho g h = \frac{1}{2}\rho v_2^2 \left(1 - \frac{S_2^2}{S_1^2}\right) \tag{9.7.203}$$

As $S_1 > S_2$ the second member of the relation is positive and therefore $P_1 > P_2$: there is therefore a pressure drop in the tight part of the tube. On arriving at the divergent region again in $S_3 = S_2$, the pressure of the fluid increases again and the speed takes back its initial value. This decrease in pressure which accompanies the increase in speed is named the "Bernoulli effect" or "Venturi effect".

Thus, the velocity of the fluid increases in a bottleneck to satisfy the equation of continuity (conservation of the flux / mass) and the fact that it is incompressible (otherwise there would be a sort of plug).

Remark

Paradoxically, the Venturi effect also occurs when atmospheric air cross a summit or crest or also in the streets of cities. Indeed, the air that arrives on the mountain or the crest tends to "crash" on it. The cross-section of air flow at the top is therefore lower than at the base. There is therefore also a Venturi effect: the wind speed is higher on the summits and the ridges than at the bottom (the professionals of the glider know something ...). The Venturi effect is also a dangerous phenomenon to take into account when building maintenance works occurs in cities near tunnels. Indeed, as the speed of wind can increase dramatically near the exit of the tunnel it can damage or simply take down all maintenance installation (in such a configuration an accident happened in Fribourg in Switzerland a few years ago).

The Venturi tube is used in aerospace to measure the relative speed in flight, but also in automotive carburettors and in airbrushes. The Venturi tube is also used in industrial sites to measure the flow of a fluid in a pipe.

From the last relation, we derive trivially a very useful equality in practice:

$$v_2 = \sqrt{\frac{2\rho g h}{1 - \dfrac{S_2^2}{S_1^2}}} = \sqrt{\frac{\Delta P}{1 - \dfrac{S_2^2}{S_1^2}}} \tag{9.7.204}$$

that it is sufficient to multiply by the surface S_2 to have the flow rate in the connection.

Obviously we have identically:

$$v_1 = \sqrt{\frac{2\rho g h}{\dfrac{S_1^2}{S_2^2} - 1}} = \sqrt{\frac{\Delta P}{\dfrac{S_1^2}{S_2^2} - 1}} \tag{9.7.205}$$

Here is a typical Venturi tube to measures the D_1 flow rate thanks to pressure differential:

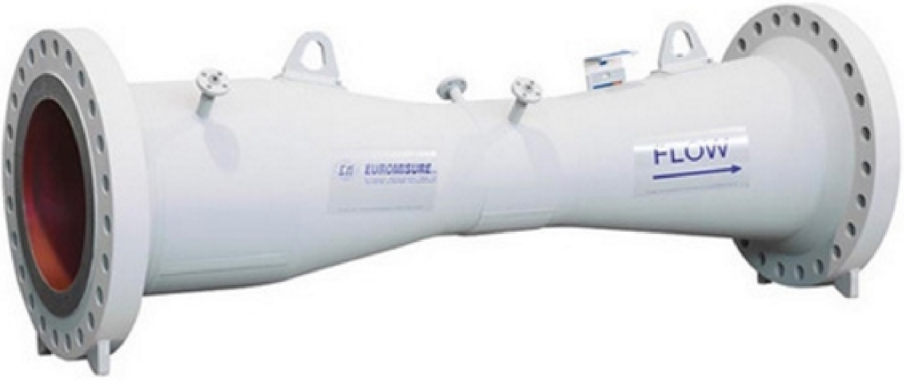

Figure 9.235: **Industrial Venturi tube (source: WIKA)**

For (old) airplanes as already mentioned Venturi tube can be used to measure relative velocity of the plane:

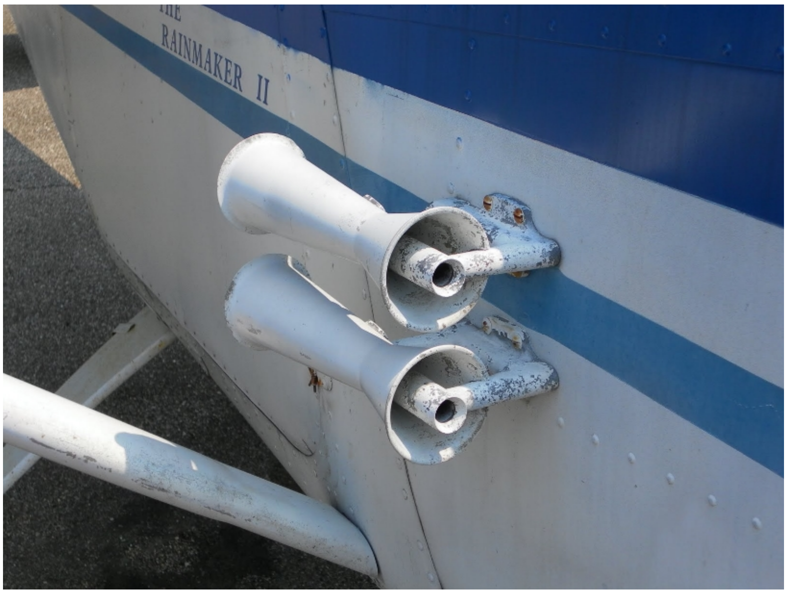

Figure 9.236: **Venturi tube on a CESSNA**

9.7.2.3.6 Pitot Tube

The Pitot tube is used to measure the flow velocity of a perfect subsonic fluid / gas (assumed to be in continuous flow). The Pitot tube most commonly used in aeronautics consists in forming in a tube a pressure tapping orifice at A and at B as visible in the figure below:

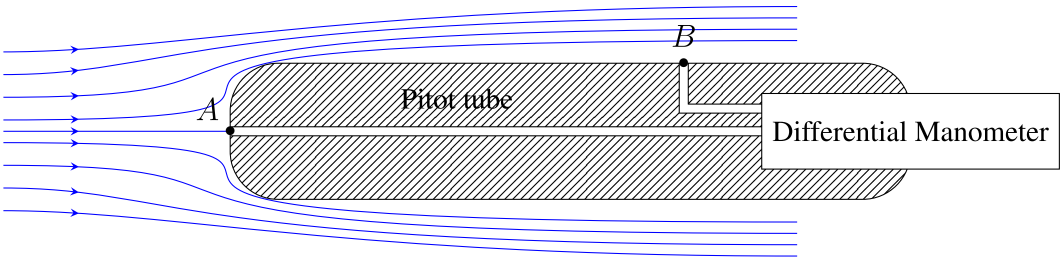

Figure 9.237: **Horizontal Pitot tube (source: http://femto-physique.fr, author: Jimmy Roussel)**

Point A is a stop point because the velocity is zero (there is no flow in the orifice, it is just a pressure tap). Far from the obstacle (the Pitot tube) the flow is assumed to in uniform speed vand pressure P_B

At A (breakpoint), using the Bernoulli equation along the current line and considering the variation in height between A and B negligible, the pressure is equal to:

$$P_A = P_B + \frac{1}{2}\rho v^2 \tag{9.7.206}$$

Therefore have:

$$\boxed{v = \sqrt{2(P_A - P_B)}\rho} \tag{9.7.207}$$

So for aircraft from the difference of a measure of pressure and knowledge of gas density, it is possible to know the speed! By multiplying by the section of the conduit we also have the corresponding flow rate.

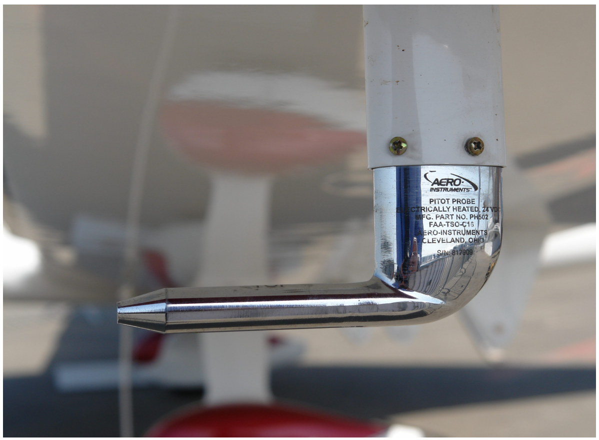

Figure 9.238: **Real Pitot tube**

Likely due to the aircraft's Pitot tubes being obstructed by ice crystals – caused the autopilot to disconnect, after which the crew reacted incorrectly and ultimately caused the aircraft to enter an aerodynamic stall from which it did not recover - the Air France Flight 447 (AF447/AFR447) from Rio de Janeiro to Paris was the deadliest in the history of Air France on 1 June 12009 (holocene calendar) with 228 deaths.

Remark

In aeronautics, the dynamic pressure is added to the static pressure (of ambient atmosphere) to give the total pressure which can be measured at the point of zero velocity of the Pitot tube. By removing the static pressure, one finds the "dynamic pressure".

There is another variant of the Pitot tube more used in the industrial field of which here is a diagram:

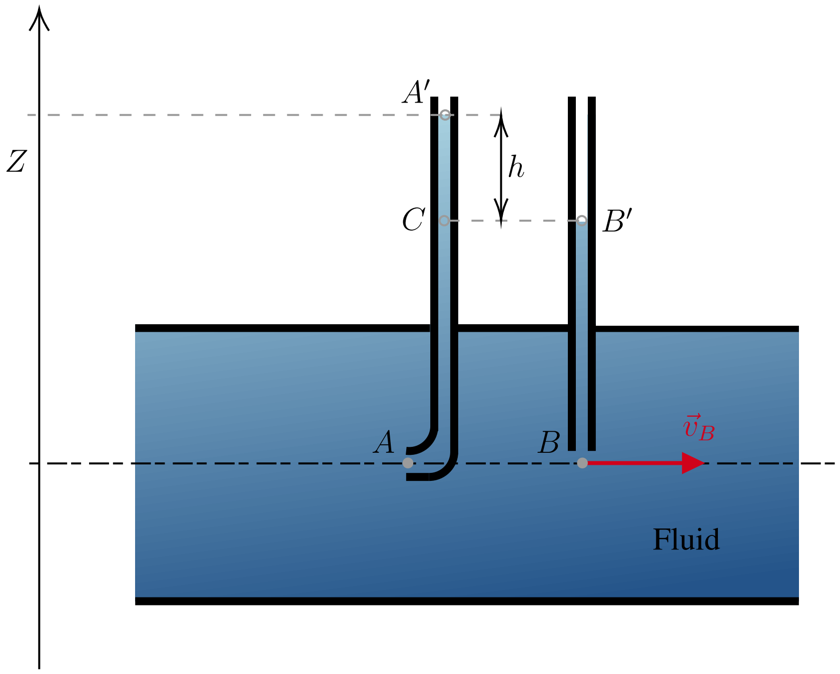

Figure 9.239: **Vertical Pitot tube**

We therefore also apply the Bernoulli theorem on the axis of the pipe. We have then in it (we detail one the developments a little more than in the previous example):

$$P_A+\rho g Z_A+\frac{1}{2}\rho v_A^2=P_B+\rho g Z_B+\frac{1}{2}\rho v_B^2 \tag{9.7.208}$$

but:

$$Z_A=Z_B \qquad v_A=0 \qquad v_B=v \tag{9.7.209}$$

and therefore:

$$P_A=P_B+\frac{1}{2}\rho v_B^2 \tag{9.7.210}$$

But we also have using the fundamental theorem of hydrostatics:

$$\begin{aligned}P_A&=P_{A'}+\rho g(Z_{A'}-Z_A)\cong P_{\text{atm}}+\rho g(Z_{A'}-Z_A)\\P_B&=P_{B'}+\rho g(Z_{B'}-Z_B)\cong P_{\text{atm}}+\rho g(Z_{B'}-Z_B)=P_{\text{atm}}+\rho g(Z_{B'}-Z_A)\end{aligned} \tag{9.7.211}$$

We have then:

$$P_A=P_B+\frac{1}{2}\rho v_B^2\Rightarrow P_{\text{atm}}+\rho g(Z_{A'}-Z_A)=(P_{\text{atm}}+\rho g(Z_{B'}-Z_A))+\frac{1}{2}\rho v_B^2 \tag{9.7.212}$$

Therefore:

$$\boxed{v=\sqrt{2g(Z_{A'}-Z_{B'})}=\sqrt{2gh}} \tag{9.7.213}$$

9.7.2.3.7 Pressure drop (pressure loss)

Pressure drop is defined as the difference in pressure between two points of a fluid carrying network. Pressure drop occurs when frictional forces, caused by the resistance to flow, act on a fluid as it flows through the tube. The main determinants of resistance to fluid flow are fluid velocity through the pipe and fluid viscosity.

When there is no machine (no pump or turbine) in the flow of a perfect fluid between points (1) and (2) of the same current line, the Bernoulli relation can be written In the following form:

$$\frac{1}{2}\rho(v_2^2-v_1^2)+\rho g(z_2-z_1)+(P_2-P_1)=0 \tag{9.7.214}$$

When the fluid passes through a hydraulic machine, it exchanges energy with this machine in form of work for a given time. The power P exchanged is then (see section Classical Mechanics page 3379):

$$P=\frac{\Delta W}{\Delta t} \tag{9.7.215}$$

Where by convention, if $P>0$ the energy is received by the fluid (pump) otherwise, if $P<0$ the energy is supplied by the fluid (turbine).

If the volumetric flow is Q_V then Bernoulli's relation is written logically:

$$\frac{1}{2}\rho(v_2^2-v_1^2)+\rho g(z_2-z_1)+(P_2-P_1)=w \tag{9.7.216}$$

where:

$$w=\frac{P}{Q_V}\;[\mathrm{J}\cdot\mathrm{m}^{-3}] \tag{9.7.217}$$

A perfect fluid does not exist. During a flow in a pipe, the friction forces dissipate part of the kinetic and potential energy, which results in the existence of pressure losses which must be taken into account.

Let us consider a stationary and incompressible horizontal cylindrical flow. If we apply the Bernoulli relation between input and output, we obtain:

$$P_1=P_2 \tag{9.7.218}$$

However, experimentally, we observe that we must impose a higher input pressure to maintain the steady state. Indeed, the viscosity forces resist to the flow. It is therefore necessary to impose an overpressure ΔP_f which we name the "pressure loss" and that is due to the existence of frictional forces (viscosity) or singular losses (geometry of the distribution circuits).

The "generalized Bernoulli equation (for liquids)" is then written in this case of study which is part of the field of process engineering:

$$\boxed{\frac{1}{2}\rho v_1^2+\rho g z_1+P_1+\frac{P}{Q_V}=\frac{1}{2}\rho v_2^2+\rho g z_2+P_2+\Delta P_f} \qquad (9.7.219)$$

This relationship is often used in the theoretical (...) study of pipeline problems.

In practice, the pressure drop is calculated from the Poiseuille law which we have already demonstrated earlier above:

$$J=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l} \qquad (9.7.220)$$

where for recall J is the traditional notation of the volumetric flow in this particular field.

What is interesting to observe with the Poiseulle law in the case of the analysis of the pressure losses is that the volumetric flow is therefore inversely proportional to the distance l of the horizontal pipe. Thus, the loss of pressure and therefore the pressure at the end of a pipe is very easily calculated by rearranging the above relationship:

$$\boxed{P_1=P_2-\frac{J8\mu_d l}{\pi R^4}} \qquad (9.7.221)$$

So obviously the pressure at the end of a pipe is less than the pressure at its beginning.

9.7.2.4 Navier-Stokes Equations

Let us consider an elementary parallelepiped extracted from a static fluid at equilibrium of dimensions $\mathrm{d}x$, $\mathrm{d}y$, $\mathrm{d}z$ represented in the figure below. The equilibrium material composing the parallelepiped is generally subjected to volumetric forces in all directions (Pascal's theorem) whose components on the three orthogonal axes are represented in the figure below (these forces may be of Gravitational, Electromagnetic or Inertial origin...).

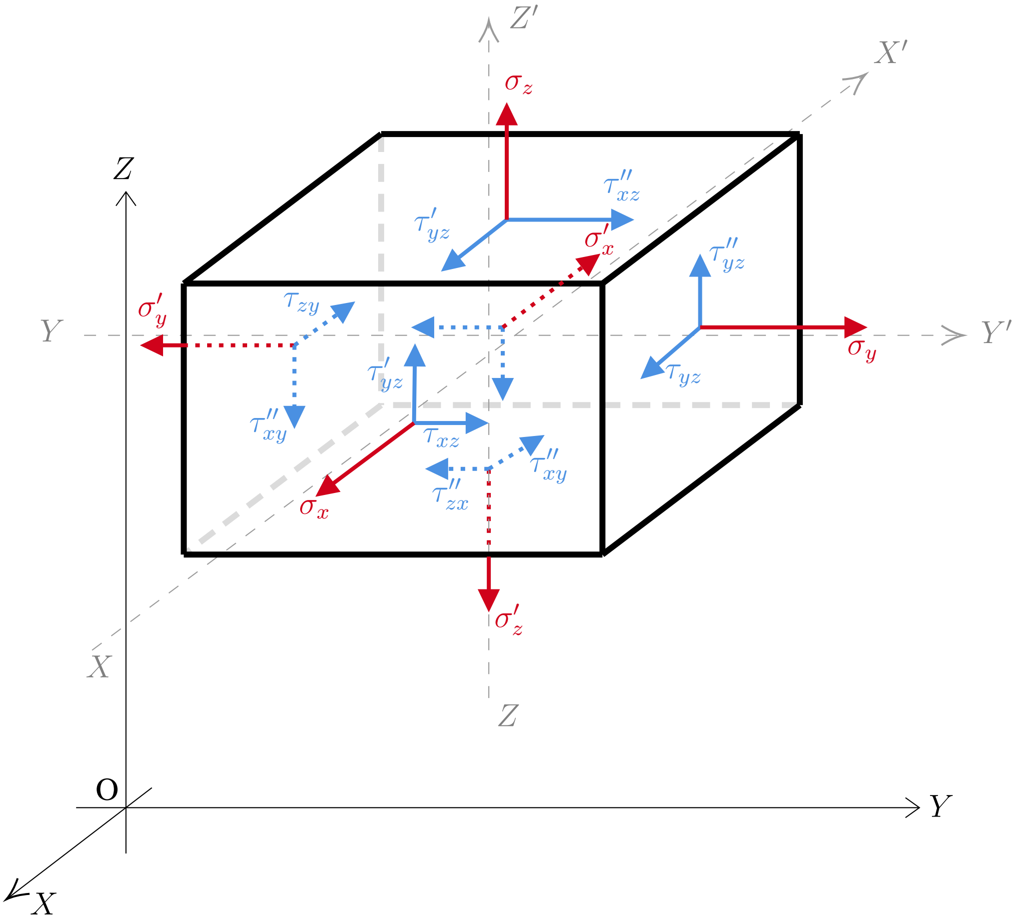

Figure 9.240: Elementary parallelepiped extracted from a static fluid at equilibrium

Remarks

R1. It is important to notice that the components of all the vectors visible in the figure above are expressed in newtons per unit area or in other words per unit pressure (which is the unit for recall... of a constraint...).

R2. It is important to be very attentive to what follows because some of the results we will get here will be reused in the section of General Relativity (see page 5720) to understand the energy-momentum tensor!!

We can, as we have represented it above, decompose and translate all the forces to which the parallelepiped is subjected to the centers of the faces of the latter. We obviously represent each of the constraints on each of the faces as the sum of the normal and tangential stresses as we did for the study of constrained solids (according to the three axes always, hence the sum of three components!).

In total, we find ourselves with 18 components of normal and tangential stresses:

$$\begin{aligned}\vec{\sigma}_x+\vec{\tau}'_{yx}+\vec{\tau}_{xz}&=\frac{\vec{F}_{+x}}{\mathrm{d}S} & \vec{\sigma}'_x+\vec{\tau}'_{xy}+\vec{\tau}_{zx}&=\frac{\vec{F}_{-x}}{\mathrm{d}S}\\ \vec{\sigma}_y+\vec{\tau}'_{yz}+\vec{\tau}_{yx}&=\frac{\vec{F}_{+y}}{\mathrm{d}S} & \vec{\sigma}'_y+\vec{\tau}'_{zy}+\vec{\tau}''_{xy}&=\frac{\vec{F}_{-y}}{\mathrm{d}S}\\ \vec{\sigma}_z+\vec{\tau}''_{xz}+\vec{\tau}'_{yz}&=\frac{\vec{F}_{+z}}{\mathrm{d}S} & \vec{\sigma}'_z+\vec{\tau}''_{zx}+\vec{\tau}'_{zy}&=\frac{\vec{F}_{-z}}{\mathrm{d}S}\end{aligned}\tag{9.7.222}$$

We try to minimize the number of normal components in order to determine the sufficient constraints on each of the axes. Therefore we will put:

$$\begin{aligned}\vec{\sigma}_x+\vec{\sigma}'_x&=\vec{\sigma}_X\\ \vec{\sigma}_y+\vec{\sigma}'_y&=\vec{\sigma}_Y\\ \vec{\sigma}_z+\vec{\sigma}'_z&=\vec{\sigma}_Z\end{aligned}\tag{9.7.223}$$

Thus, three components are sufficient to know the normal stress forces on the surfaces along each axis.

If we make the sum of the moments of forces with respect to the centers of gravity for each axis of symmetry of the parallelepiped (XX',YY',ZZ'), it is evident that of the 12 tangential components 6 are sufficient to describe the whole of system.

Therefore for the $X\mathrm{O}Y$ plane passing through the center of gravity we have:

$$\begin{aligned}&(\vec{\tau}_{zy}\mathrm{d}x\mathrm{d}x)\frac{\mathrm{d}y}{2}+(\vec{\tau}_{zx}\mathrm{d}y\mathrm{d}z)\frac{\mathrm{d}x}{2}+(\vec{\tau}\mathrm{d}x\mathrm{d}z)\frac{\mathrm{d}y}{2}+(\vec{\tau}_{xz}\mathrm{d}z\mathrm{d}y)\frac{\mathrm{d}x}{2}\\ &=\frac{1}{2}\mathrm{d}V\left[(\vec{\tau}_{zy}+\vec{\tau}_{yz})+(\vec{\tau}_{zx}+\vec{\tau}_{xz})\right]=\frac{1}{2}\mathrm{d}V\left[\vec{\tau}_{ZY}+\vec{\tau}_{ZX}\right]=\frac{1}{2}\mathrm{d}V\vec{\tau}_{X\mathrm{O}Y}\end{aligned}\tag{9.7.224}$$

For the $X\mathrm{O}Z$ plane:

$$\begin{aligned}&(\vec{\tau}'_{yx}\mathrm{d}y\mathrm{d}z)\frac{\mathrm{d}x}{2}+(\vec{\tau}'_{yz}\mathrm{d}x\mathrm{d}y)\frac{\mathrm{d}z}{2}+(\vec{\tau}'_{xy}\mathrm{d}z\mathrm{d}y)\frac{\mathrm{d}x}{2}+(\vec{\tau}'_{zy}\mathrm{d}y\mathrm{d}x)\frac{\mathrm{d}z}{2}\\ &=\frac{1}{2}\mathrm{d}V\left[(\vec{\tau}'_{yx}+\vec{\tau}'_{xy})+(\vec{\tau}''_{yz}+\vec{\tau}'_{zy})\right]=\frac{1}{2}\mathrm{d}V\left[\vec{\tau}_{YX}+\vec{\tau}_{YZ}\right]=\frac{1}{2}\mathrm{d}V\vec{\tau}_{X\mathrm{O}Z}\end{aligned}\tag{9.7.225}$$

For the $Z\mathrm{O}Y$ plane:

$$\begin{aligned}&(\vec{\tau}''_{xz}\mathrm{d}x\mathrm{d}y)\frac{\mathrm{d}z}{2}+(\vec{\tau}''_{yx}\mathrm{d}x\mathrm{d}z)\frac{\mathrm{d}y}{2}+(\vec{\tau}''_{zx}\mathrm{d}y\mathrm{d}x)\frac{\mathrm{d}z}{2}+(\vec{\tau}''_{xy}\mathrm{d}z\mathrm{d}x)\frac{\mathrm{d}y}{2}\\ &=\frac{1}{2}\mathrm{d}V\left[(\vec{\tau}''_{xz}+\vec{\tau}''_{zx})+(\vec{\tau}''_{yx}+\vec{\tau}''_{xy})\right]=\frac{1}{2}\mathrm{d}V\left[\vec{\tau}_{ZX}+\vec{\tau}_{XY}\right]=\frac{1}{2}\mathrm{d}V\vec{\tau}_{Z\mathrm{O}Y}\end{aligned}\tag{9.7.226}$$

We can obtain the same components of equilibrium by considering this time a static regular elementary tetrahedron (extracted from the cube). The aim is to demonstrate that we find the 6 components determined previously.

Figure 9.241: Regular elemental tetrahedron extracted from a fluid at equilibrium

Remark

It is important to notice again that the components of all the vectors visible in the figure above are expressed in newtons per unit area or in other words per unit of pressure (which is the unit of constraints for recall...).

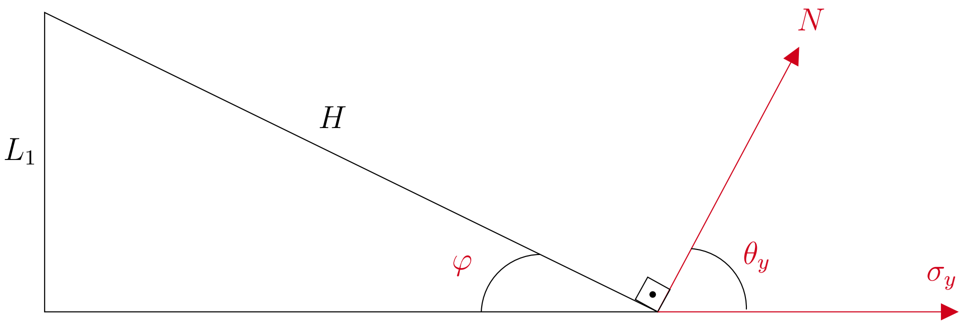
To know the surface of the faces OAC, OBC, OAB, we multiply the surface ABC (denoted hereafter: S) by the cosine of the angle that form the vectors $\vec{\sigma}_i$ and $\vec{N}$.

Indeed, given the surfaces:

$$S_y=\frac{L_1\cdot L_1}{2} \qquad \text{and} \qquad S=\frac{H\cdot\overline{AC}}{2}=\frac{H\cdot 2L_1\cos\left(\dfrac{\pi}{4}\right)}{2}=HL_1\frac{\sqrt{2}}{2} \tag{9.7.227}$$

However, let us try to express the S_i according to S. The schema below (slice of the tetrahedron) should help to understand the reasoning:

$$\varphi=\pi-\frac{\pi}{2}-\theta_y=\frac{\pi}{2}-\theta_y \tag{9.7.228}$$



N
H
L_1
φ
θ_y
σ_y

and therefore:

$$\sin(\varphi)=\frac{L_1}{H}=\sin\left(\frac{\pi}{2}-\theta_y\right)=\cos(\theta_y) \tag{9.7.229}$$

Finally:

$$S_y=\frac{H\cos(\theta_y)L_1}{2} \tag{9.7.230}$$

The ratio:

$$\frac{S_y}{S}=\frac{\dfrac{H\cos(\theta_y)L_1}{2}}{HL_1\dfrac{\sqrt{2}}{2}}=\frac{\cos(\theta_y)}{\sqrt{2}} \tag{9.7.231}$$

hence:

$$S_y=\frac{S}{\sqrt{2}}\cos(\theta_y) \tag{9.7.232}$$

The principle of analysis being the same for all other surfaces such as:

$$S_x=\frac{S}{\sqrt{2}}\cos(\theta_x)\qquad S_y=\frac{S}{\sqrt{2}}\cos(\theta_y)\qquad S_z=\frac{S}{\sqrt{2}}\cos(\theta_z) \tag{9.7.233}$$

We will write:

$$\frac{\cos(\theta_x)}{\sqrt{2}}=l\qquad\frac{\cos(\theta_y)}{\sqrt{2}}=m\qquad\frac{\cos(\theta_z)}{\sqrt{2}}=n \tag{9.7.234}$$

such that:

$$S_x=Sl\qquad S_y=Sm\qquad S_z=Sn \tag{9.7.235}$$

Remark

We can easily know the values of the θ_i using vector analysis. Indeed, the plane ABC being of equation (see section Analytical Geometry page 2800):

$$ax+by+cz+d=0\qquad a=b=c=L_1 \tag{9.7.236}$$

by simplifying by L_1:

$$1\cdot x+1\cdot y+1\cdot z+d'=0 \tag{9.7.237}$$

The vector normal to the plane being indeed:

$$\vec{N}=(1,1,1) \tag{9.7.238}$$

To know the cosines of the angle of the normal vector with the $\vec{\sigma}_i$, it is enough to assimilate these to the basis vectors $(\vec{i},\vec{j},\vec{k})$ such that (elementary trigonometry):

$$\cos(\theta_i)=\frac{\|\vec{i}\|}{\|\vec{N}\|}=\frac{||(1,0,0)||}{||(1,1,1)||}=\frac{1}{\sqrt{3}} \tag{9.7.239}$$

and proceeding in the same way for all the other θ.

The equilibrium of forces gives us:

$$N_xS-\sigma_xSl-\tau_{xy}Sm-\tau_{xz}Sn=0 \tag{9.7.240}$$

After simplification:

$$N_x=\sigma_xl+\tau_{xy}m+\tau_{xz}n \tag{9.7.241}$$

Following to the other axes:

$$\begin{aligned}N_y&=\tau_{yx}l+\sigma_ym+\tau_{yz}n\\N_z&=\tau_{zx}l+\tau_{zy}m+\sigma_zn\end{aligned} \tag{9.7.242}$$

In summary:

$$\begin{aligned}N_x&=\sigma_xl+\tau_{xy}m+\tau_{xz}nN_y&&=\tau_{yx}l+\sigma_ym+\tau_{yz}n\\N_z&=\tau_{zx}l+\tau_{zy}m+\sigma_zn\end{aligned} \tag{9.7.243}$$

Using the matrix representation, we get:

$$\boxed{\begin{bmatrix}N_x\\N_y\\N_z\end{bmatrix}=\begin{bmatrix}\sigma_{xx}&\tau_{xy}&\tau_{xz}\\\tau_{yx}&\sigma_{yy}&\tau_{yz}\\\tau_{zx}&\tau_{zy}&\sigma_{zz}\end{bmatrix}\begin{bmatrix}l\\m\\n\end{bmatrix}} \tag{9.7.244}$$

Either in index notation the normal and tangential constraints are given by the following traditional relation (where we do not distinguish what is tangential from what is normal so there is a loss of clarity that is typical habit of solid states physicists...):

$$\boxed{N_i=\sigma_{ij}n_j=\sum_j\sigma_{ij}n_j} \tag{9.7.245}$$

We see appear a mathematical quantity σ_{ij} having 9 components (corresponding for recall to the vector of the stress-forces projected into the nine 2×2 combinations of axis xx, zz, yy and planes $xy=yx$, $yz=zy$, $zx=xz$), whereas a vector in the same space $\mathbb{R}^3$ possesses 3 components. We know this kind of mathematical being that we have already studied in the in the section of Tensor Calculus. The quantity σ_{ij} is named "second order stress tensor" or "Cauchy stress tensor". Moreover, some components can be equal ($\sigma_{ij}=\sigma_{ji}$, if $i\neq j$), which would make it symmetrical. It then has only the 6 distinct components, relative to the numbers of components sufficient to completely describe a system at equilibrium.

To study the deformations of a continuous medium such as a fluid, we will first consider the case of very small deformations. The small displacements $\vec{D}$ of a point will be represented by (u,v,w) parallel to the axes of a referential OXYZ. We assume that these components are very small quantities continuously varying in the volume of the considerated body.

Let us consider a linear segment $\overline{\text{O}P}$ located in a solid before deformation. In an OXYZ repository, we will denote by (x_0,y_0,z_0) and (x_p,y_p,z_p) the coordinates of O and P.

During the deformation, the line $\overline{\text{O}P}$ becomes $\overline{\text{O}'P'}$ as shown below:

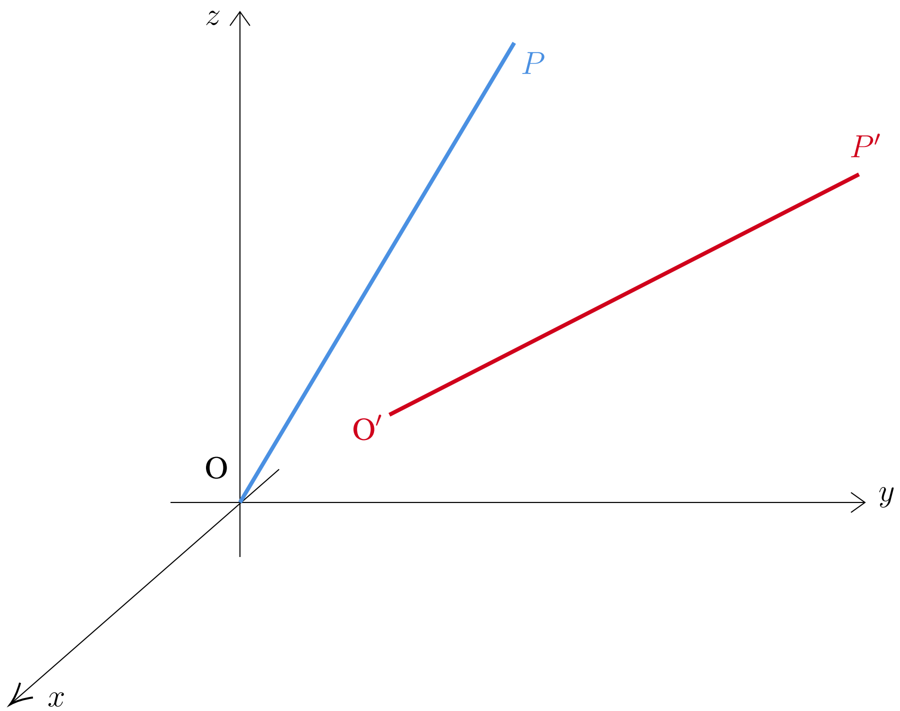


Figure 9.242: **Linear segment in a solid of fluid before and after deformation**

Given u_0, v_0, w_0 the displacements of the point O parallel to the axes OX, OY, OZ and u_p, v_p, w_p the displacements of the point P parallel to the same axes.

The coordinates of the points O′ and P' are then:

$$(x_0+u_0,y_0+v_0,z_0+w_0) \qquad \text{and} \qquad (x_p+u_p,y_p+v_p,z_p+w_p) \tag{9.7.246}$$

Before deformation, given L the length $\overline{\mathrm{O}P}$:

$$L^2=(x_p-x_0)^2+(y_p-y_0)^2+(z_p-z_0)^2 \tag{9.7.247}$$

After deformation, we have a length L' being equal to:

$$L'^2=[(x_p+u_p)-(x_0+u_0)]^2+[(y_p+v_p)-(y_0+v_0)]^2+[(z_p+w_p)-(z_0+w_0)]^2 \tag{9.7.248}$$

If ΔL is the elongation of the element $\overline{\mathrm{O}P}$ during the deformation, we have:

$$L'^2=(L+\Delta L)^2=L^2+2L\Delta L+\Delta L^2 \tag{9.7.249}$$

By carrying out the following transformations:

$$\begin{aligned}L'^2=L^2+2L\Delta L+\Delta L^2=&\\ &\left[(x_p+u_p)^2+(x_0+u_0)^2-2(x_p+u_p)(x_0+u_0)\right]+\\ &\left[(y_p+v_p)^2+(y_0+v_0)^2-2(y_p+v_p)(y_0+v_0)\right]+\\ &\left[(z_p+w_p)^2+(z_0+w_0)^2-2(z_p+w_p)(z_0+w_0)\right]\end{aligned} \tag{9.7.250}$$

By developing:

$$\begin{aligned}&[x_p^2+u_p^2+2x_pu_p+x_0^2+u_0^2+2x_0u_0-2x_px_0-2x_pu_0-2x_0u_p-2u_pu_0]+\\ &[y_p^2+v_p^2+2y_pv_p+y_0^2+v_0^2+2y_0v_0-2y_py_0-2y_pv_0-2y_0v_p-2v_pv_0]+\\ &[z_p^2+w_p^2+2z_pw_p+z_0^2+w_0^2+2z_0w_0-2z_pz_0-2z_pw_0-2z_0w_p-2w_pw_0]\end{aligned} \tag{9.7.251}$$

Therefore:

$$\begin{aligned}&L^2+2L\Delta L+\Delta L^2=\\&\left[(x_p-x_0)^2+(y_p-y_0)^2+(z_p-z_0)^2\right]+\\&2\left[(x_p-x_0)(u_p-u_0)+(y_p-y_0)(v_p-v_0)+(z_p-z_0)(w_p-w_0)\right]+\\&\left[(u_p-u_0)^2+(v_p-v_0)^2+(w_p-w_0)^2\right]\end{aligned} \tag{9.7.252}$$

By neglecting the terms of displacement of higher order and taking into account the relation:

$$L^2=(x_p-x_0)^2+(y_p-y_0)^2+(z_p-z_0)^2 \tag{9.7.253}$$

It comes that L^2 disappears with $(x_p-x_0)^2+(y_p-y_0)^2+(z_p-z_0)^2$ as well as the terms squared, we have then:

$$\frac{\Delta L}{L}=\frac{1}{L^2}\left[(x_p-x_0)(u_p-u_0)+(y_p-y_0)(v_p-v_0)+(z_p-z_0)(w_p-w_0)\right] \tag{9.7.254}$$

But the Analytical Geometry (elementary trigonometry: ratio of the sides opposite and adjacent to the hypotenuse) gives the following relations:

$$\frac{x_p-x_0}{L}=l \qquad \frac{y_p-y_0}{L}=m \qquad \frac{z_p-z_0}{L}=n \tag{9.7.255}$$

which are the direction cosines of line L.

We can then write:

$$\varepsilon=\frac{\Delta L}{L}=\frac{l}{L}(u_p-u_0)+\frac{m}{L}(v_p-v_0)+\frac{n}{L}(w_p-w_0) \tag{9.7.256}$$

The variation u_p being a small displacement, we use a Taylor series development (see section Sequences and Series page 1714) whose upper order terms are neglected (linearisation of equations):

$$u_p=u+x_p\partial_x u+y_p\partial_y u+z_p\partial_z u \tag{9.7.257}$$

We also have:

$$u_0=u+x_0\partial_x u+y_0\partial_y u+z_0\partial_z u \tag{9.7.258}$$

The difference gives:

$$u_p-u_0=(x_p-x_0)\partial_x u+(y_p-y_0)\partial_y u+(z_p-z_0)\partial_z u \tag{9.7.259}$$

So we can now write:

$$\begin{aligned}u_p-u_0&=lL\partial_x u+mL\partial_y u+nL\partial_z u\\v_p-v_0&=lL\partial_x v+mL\partial_y v+nL\partial_z v\\w_p-w_0&=lL\partial_x w+mL\partial_y w+nL\partial_z w\end{aligned} \tag{9.7.260}$$

Finally:

$$\begin{aligned}\varepsilon&=\frac{l}{L}(lL\partial_x u+mL\partial_y u+nL\partial_z u)+\frac{m}{L}(lL\partial_x v+mL\partial_y v+nL\partial_z v)+\frac{n}{L}(lL\partial_x w+mL\partial_y w+nL\partial_z w)\\&=l^2\partial_x u+ml\partial_y u+nl\partial_z u+ml\partial_x v+m^2\partial_y v+mn\partial_z v+nl\partial_x w+mn\partial_y w+n^2\partial_z w\end{aligned} \tag{9.7.261}$$

By grouping, we have:

$$\varepsilon = l^2\partial_x u + m^2\partial_y v + n^2\partial_z w + mn(\partial_z v + \partial_y w) + nl(\partial_z u + \partial_x w) + ml(\partial_y u + \partial_x v) \quad (9.7.262)$$

This expression allows, at any point, the computation of the deformation ε in a direction having as cosine direction l, m, n as a function of the displacements u, v, w at this point.

Let us consider the case where the line L coincides with the axis OX, we have $l=1$, $m=n=0$ the preceding equation then becomes:

$$\varepsilon_x = \partial_x u \quad (9.7.263)$$

We have, if L coincides with the OY axis ($m=1$, $l=n=0$) or with the OZ axis ($n=1$, $l=m=0$):

$$\varepsilon_y = \partial_y v \qquad \text{and} \qquad \varepsilon_z = \partial_z w \quad (9.7.264)$$

The quantities ε_x, ε_y, ε_z are named "normal deformations" and have no dimensional units.

For the interpretation of the terms $(\partial_z v + \partial_y w)$, $(\partial_z u + \partial_x w)$, $(\partial_y u + \partial_x v)$, we refer to the following figure:

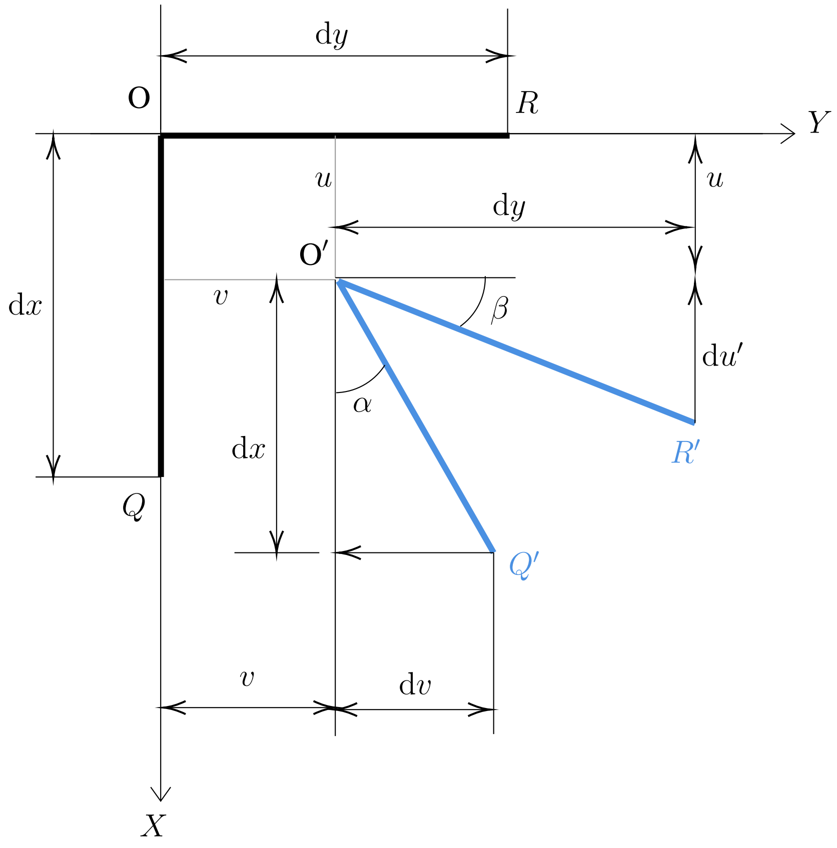

Figure 9.243: Situation that allows to make emerge shear stresses

Given two line segments $\overline{\text{O}R}$ and $\overline{\text{O}Q}$ located in the plane XOY. Before deformation $\overline{\text{O}R}$ and $\overline{\text{O}Q}$ coincided with the orthonormal referential YOX. After deformation, they can take the position $\overline{\text{O}'R'}$ and $\overline{\text{O}'Q'}$. The components of the displacement of O are u and v.

- The displacement component of R' is calculated as follows:

$$\mathrm{d}u = \mathrm{d}y\tan(\beta) \tag{9.7.265}$$

  with:

$$\beta \cong \tan(\beta) = \frac{\mathrm{d}u}{\mathrm{d}y} \tag{9.7.266}$$

  as the angle is small.

  In general, as $u = f(x,y,z)$, we will write:

$$\beta = \partial_y u \tag{9.7.267}$$

- The component of the displacement of Q' is it:

$$\alpha = \partial_x v \tag{9.7.268}$$

As before deformation, the angle $\widehat{Q\mathrm{O}R}$ is of $\pi/2$, after deformation, the right angle is reduced of a quantity $\alpha+\beta$. This reduction equation is named the "shear deformation" or "tangential deformation" and is denoted by γ_{xy}.

We will proceed in the same way for the other terms, hence:

$$\begin{aligned}\gamma_{xy} &= \partial_y u + \partial_x v\\ \gamma_{xz} &= \partial_z u + \partial_x w\\ \gamma_{yz} &= \partial_z v + \partial_y w\end{aligned} \tag{9.7.269}$$

Seeing what precedes, it is customary to define the "matrix of differential operators":

$$\boxed{\begin{bmatrix}\varepsilon_x\\ \varepsilon_y\\ \varepsilon_z\end{bmatrix} = D_{ij}\begin{bmatrix}u\\ v\\ w\end{bmatrix} = \begin{bmatrix}\partial_x & 0 & 0\\ 0 & \partial_y & 0\\ 0 & 0 & \partial_z\\ \partial_y & \partial_x & 0\\ 0 & \partial_z & \partial_y\\ \partial_z & 0 & \partial_x\end{bmatrix}\begin{bmatrix}u\\ v\\ w\end{bmatrix}} \tag{9.7.270}$$

Given the quadruplet of groups of equations previously demonstrated in this section (see deformations of solids):

$$\begin{aligned}
\sigma_x &= \frac{E}{1+\eta}\left[\varepsilon_x+\frac{\eta}{1-2\eta}(\varepsilon_x+\varepsilon_y+\varepsilon_z)\right]\\
\sigma_y &= \frac{E}{1+\eta}\left[\varepsilon_y+\frac{\eta}{1-2\eta}(\varepsilon_x+\varepsilon_y+\varepsilon_z)\right]\\
\sigma_x &= \frac{E}{1+\eta}\left[\varepsilon_x+\frac{\eta}{1-2\eta}(\varepsilon_x+\varepsilon_y+\varepsilon_z)\right]
\end{aligned}$$

$$\gamma_{xy}=\partial_y u+\partial_x v \qquad \gamma_{xz}=\partial_z u+\partial_x w \qquad \gamma_{yz}=\partial_z v+\partial_y w \tag{9.7.271}$$

$$\begin{bmatrix} N_x\\ N_y\\ N_z\end{bmatrix}=\begin{bmatrix}\sigma_{xx} & \tau_{xy} & \tau_{xz}\\ \tau_{yx} & \sigma_{yy} & \tau_{yz}\\ \tau_{zx} & \tau_{zy} & \sigma_{zz}\end{bmatrix}\begin{bmatrix} l\\ m\\ n\end{bmatrix}$$

$$\tau=\frac{E}{2(1+\eta)}\gamma$$

We can summarize:

$$\begin{aligned}
\sigma_{xx} &= \frac{E}{1+\eta}\left[\varepsilon_{xx}+\frac{\eta}{1-2\eta}(\varepsilon_{xx}+\varepsilon_{yy}+\varepsilon_{zz})\right]\\
\sigma_{yy} &= \frac{E}{1+\eta}\left[\varepsilon_{yy}+\frac{\eta}{1-2\eta}(\varepsilon_{xx}+\varepsilon_{yy}+\varepsilon_{zz})\right]\\
\sigma_{zz} &= \frac{E}{1+\eta}\left[\varepsilon_{zz}+\frac{\eta}{1-2\eta}(\varepsilon_{xx}+\varepsilon_{yy}+\varepsilon_{zz})\right]
\end{aligned}$$

$$\begin{aligned}
\tau_{xy}=\tau_{yx} &= \frac{E}{2(1+\eta)}\gamma_{xy}=\frac{E}{2(1+\eta)}(\partial_y u+\partial_x v)\\
\tau_{yz}=\tau_{zy} &= \frac{E}{2(1+\eta)}\gamma_{yz}=\frac{E}{2(1+\eta)}(\partial_z v+\partial_y w)\\
\tau_{xz}=\tau_{zy} &= \frac{E}{2(1+\eta)}\gamma_{zx}=\frac{E}{2(1+\eta)}(\partial_z u+\partial_x w)
\end{aligned}\tag{9.7.272}$$

At the view of the previous relations, it is customary to define the "matrix of transformation of deformation stresses":

$$\begin{bmatrix}\sigma_x\\ \sigma_y\\ \sigma_z\\ \tau_{xy}\\ \tau_{yz}\\ \tau_{zx}\end{bmatrix}=C_{ij}\begin{bmatrix}\varepsilon_x\\ \varepsilon_y\\ \varepsilon_z\\ \gamma_{xy}\\ \gamma_{yz}\\ \gamma_{yz}\\ \gamma_{zx}\end{bmatrix}=\frac{E}{(1+\eta)(1-2\eta)}\begin{bmatrix}1-\eta & \eta & \eta & 0 & 0 & 0\\ \eta & 1-\eta & \eta & 0 & 0 & 0\\ \eta & \eta & & 1-\eta & 0 & 0\\ 0 & 0 & 0 & \dfrac{1-2\eta}{2} & 0 & 0\\ 0 & 0 & 0 & 0 & \dfrac{1-2\eta}{2} & 0\\ 0 & 0 & 0 & 0 & 0 & \dfrac{1-2\eta}{2}\end{bmatrix}\begin{bmatrix}\varepsilon_x\\ \varepsilon_y\\ \varepsilon_z\\ \gamma_{xy}\\ \gamma_{yz}\\ \gamma_{zx}\end{bmatrix}\tag{9.7.273}$$

where it is possible to invert the matrix to thus obtain the "matrix of transformation of the stresses strains".

Generally, we put to simplify the notations (the reader must however not think that the shear deformation becomes a normal deformation!!!! it is only a convention of writing that must be remembered!):

$$\gamma_{xy}=2\varepsilon_{xy} \qquad \gamma_{xz}=2\varepsilon_{xz} \qquad \gamma_{yz}=2\varepsilon_{yz} \tag{9.7.274}$$

Similarly, we put:

$$\varepsilon=\varepsilon_{xx}+\varepsilon_{yy}+\varepsilon_{zz} \tag{9.7.275}$$

Thus finally:

$$\begin{aligned}\sigma_{xx}&=\frac{E}{1+\eta}\left(\varepsilon_{xx}+\frac{\eta}{1-2\eta}\varepsilon\right)\\ \sigma_{yy}&=\frac{E}{1+\eta}\left(\varepsilon_{yy}+\frac{\eta}{1-2\eta}\varepsilon\right)\\ \sigma_{zz}&=\frac{E}{1+\eta}\left(\varepsilon_{zz}+\frac{\eta}{1-2\eta}\varepsilon\right)\end{aligned} \tag{9.7.276}$$

$$\begin{aligned}\tau_{xy}=\tau_{yx}&=\frac{E}{2(1+\eta)}2\varepsilon_{xy}\\ \tau_{yz}=\tau_{zy}&=\frac{E}{2(1+\eta)}2\varepsilon_{yz}\\ \tau_{xz}=\tau_{zx}&=\frac{E}{2(1+\eta)}2\varepsilon_{zy}\end{aligned}$$

Taking into account that:

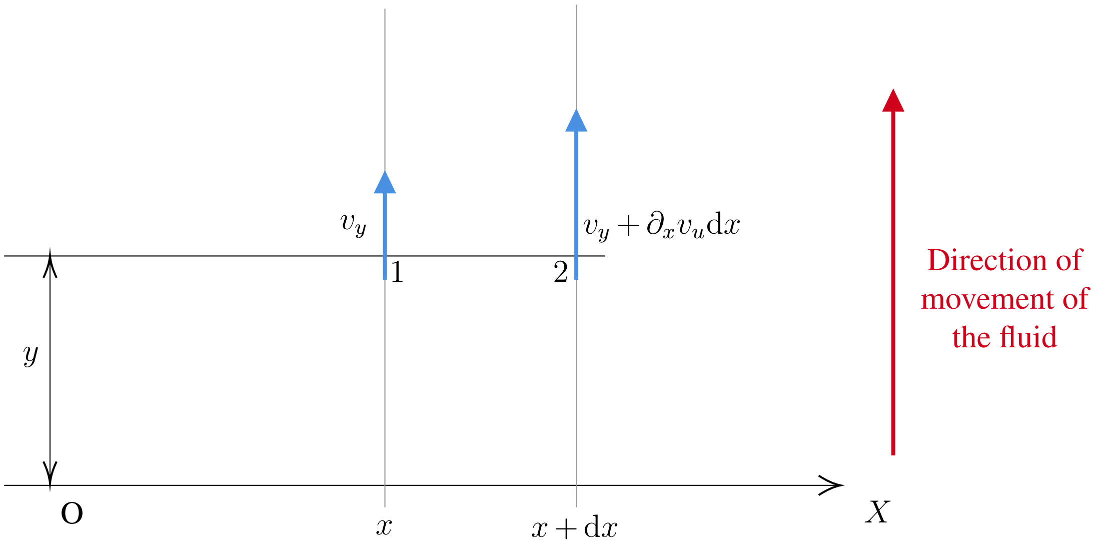
$$G=\frac{E}{2(1+\eta)} \tag{9.7.277}$$

We get the shear tensions as follows:

$$\begin{aligned}\sigma_{xx}&=2G\left(\varepsilon_{xx}+\frac{\eta}{1-2\eta}\varepsilon\right)\\ \sigma_{yy}&=2G\left(\varepsilon_{yy}+\frac{\eta}{1-2\eta}\varepsilon\right)\\ \sigma_{zz}&=2G\left(\varepsilon_{zz}+\frac{\eta}{1-2\eta}\varepsilon\right)\end{aligned} \tag{9.7.278}$$

$$\begin{aligned}\tau_{xy}=\tau_{xy}&=2G\varepsilon_{xy}\\ \tau_{yz}=\tau_{zy}&=2G\varepsilon_{yz}\\ \tau_{xz}=\tau_{zx}&=2G\varepsilon_{zy}\end{aligned}$$

Consider now, for example, a fluid flowing in the direction of OY with a velocity gradient in the direction of x:



v_y
$v_y+\partial_x v_u \mathrm{d}x$
1
2
y
O
x
$x+\mathrm{d}x$
X
Direction of movement of the fluid

Figure 9.244: **Situation that allows the emergence of normal constraints**

By placing ourselves at the level of y and at point 1 of the abscissa x, we have a velocity v_y and at point 2 of abscissa $x+\mathrm{d}x$, a speed:

$$v_y+\partial_y \mathrm{d}x \tag{9.7.279}$$

with $\partial_x v_y \neq 0$.

In the direction of x, there is no velocity component therefore:

$$v_x=0 \tag{9.7.280}$$

with $\partial_y v_x=0$.

We now assume that the shear tensions are proportional to $\partial_x v_y$ to a given factor such that:

$$\tau_{xy}=\mu_d \partial_x v_y \tag{9.7.281}$$

with for recall:

$$\mu_d=\frac{\mathrm{d}F}{\partial_z v \mathrm{d}S} \tag{9.7.282}$$

It is therefore possible to consider displacements per unit of time by putting:

$$u \rightarrow v_x \qquad v \rightarrow v_y \qquad w \rightarrow v_z \tag{9.7.283}$$

By relating the previous relation of μ_d of:

$$\begin{aligned}\tau_{xy}&=G(\partial_y u+\partial_y v)=\mu_d(\partial_y v_x+\partial_x v_y)\\ \tau_{yz}&=G(\partial_z v+\partial_y w)=\mu_d(\partial_z v_y+\partial_y v_z)\\ \tau_{zx}&=G(\partial_x w+\partial_z u)=\mu_d(\partial_x v_z+\partial_z v_x)\end{aligned} \tag{9.7.284}$$

we can say that G initially valid in a solid elastic medium considered by its displacements is the analogue of μ_d in the case of a viscous fluid considered by its displacements per unit of time. So we see that the units are conserved.

Considering also the deformations per unit of time for the normal stresses (we will return to this in detail later), we then have the system of equations:

$$\begin{aligned}
\sigma_{xx}&=2\mu_d\left(\dot{\varepsilon}_{xx}+\frac{\eta}{1-2\eta}\dot{\varepsilon}\right)=2\mu_d\theta_{xx}+2\mu_d\frac{\eta}{1-2\eta}\dot{\varepsilon}=2\mu_d\theta_{xx}+\alpha(\theta_{xx}+\theta_{yy}+\theta_{zz})\\
\sigma_{yy}&=2\mu_d\left(\dot{\varepsilon}_{yy}+\frac{\eta}{1-2\eta}\dot{\varepsilon}\right)=2\mu_d\theta_{yy}+2\mu_d\frac{\eta}{1-2\eta}\dot{\varepsilon}=2\mu_d\theta_{yy}+\alpha(\theta_{xx}+\theta_{yy}+\theta_{zz})\\
\sigma_{zz}&=2\mu_d\left(\dot{\varepsilon}_{zz}+\frac{\eta}{1-2\eta}\dot{\varepsilon}\right)=2\mu_d\theta_{zz}+2\mu_d\frac{\eta}{1-2\eta}\dot{\varepsilon}=2\mu_d\theta_{zz}+\alpha(\theta_{xx}+\theta_{yy}+\theta_{zz})
\end{aligned}\tag{9.7.285}$$

$$\begin{aligned}
\tau_{xy}&=\tau_{xy}=2\mu_d\dot{\varepsilon}_{xy}=2\mu_d\theta_{xy}\\
\tau_{yz}&=\tau_{zy}=2\mu_d\dot{\varepsilon}_{yz}=2\mu_d\theta_{yz}\\
\tau_{xz}&=\tau_{xz}=2\mu_d\dot{\varepsilon}_{zy}=2\mu_d\theta_{xz}
\end{aligned}$$

Thus, we get a condensed notation:

$$P_{ij}=2\mu_d\theta_{ij}+\alpha(\theta_{11}+\theta_{22}+\theta_{33})\delta_{ij}\tag{9.7.286}$$

where δ_{ij} is the Kronecker's symbol:

$$\delta_{ij}=\begin{cases}\delta_{ij}=1 & i=j\\ \delta_{ij}=0 & i\neq j\end{cases}\tag{9.7.287}$$

The tensor P_{ij} thus describes in part the set of stresses of a viscous fluid in which we assumed, within the framework of the Newtonian fluid hypothesis, that there are linear relations between the tensions and the normal deformations!!!!

We now put the sum of dynamic constraints in a general form that we will justify:

$$P_{ij}=2\mu_d\theta_{ij}+\alpha(\theta_{11}+\theta_{22}+\theta_{33})\delta_{ij}-p\delta_{ij}\tag{9.7.288}$$

where the term $p\delta_{ij}$ is justified by the fact that in the static case a constant dynamic pressure p always exists at a point of a fluid, situation that we do not have in the case of a solid. To justify the negative sign, we observe that in the expression of P_{ij}, the first two terms of the right-hand side correspond, in the previous study, to extension constraints while the pressure p corresponds to a compression of the fluid.

We now have to determine the coefficient α. Given $i=j$, then we have $\delta_{ij}=1$. It comes successively and by addition:

$$\begin{array}{lr}
 & P_{11}=2\mu_d\theta_{11}+\alpha(\theta_{11}+\theta_{22}+\theta_{33})-p\\
 & P_{22}=2\mu_d\theta_{22}+\alpha(\theta_{11}+\theta_{22}+\theta_{33})-p\\
+ & P_{33}=2\mu_d\theta_{33}+\alpha(\theta_{11}+\theta_{22}+\theta_{33})-p\\
\hline
\multicolumn{2}{r}{P_{11}+P_{22}+P_{33}=2\mu_d(\theta_{11}+\theta_{22}+\theta_{33})+3\alpha(\theta_{11}+\theta_{22}+\theta_{33})-3p}
\end{array}\tag{9.7.289}$$

This expression must satisfy also a fluid which is also in a static (at rest) situation such that:

$$P_{11}+P_{22}+P_{33}=-3p \tag{9.7.290}$$

It comes then that in the static case:

$$2\mu_d(\theta_{11}+\theta_{22}+\theta_{33})+3\alpha(\theta_{11}+\theta_{22}+\theta_{33})=0 \tag{9.7.291}$$

Since:

$$\theta_{11}+\theta_{22}+\theta_{33}\neq 0 \tag{9.7.292}$$

We have then:

$$2\mu_d+3\alpha=0\Rightarrow\alpha=-\frac{2}{3}\mu_d \tag{9.7.293}$$

The general expression of the constraints is then written:

$$P_{ij}=2\mu_d\theta_{ij}-\frac{2}{3}\mu_d(\theta_{11}+\theta_{22}+\theta_{33})\delta_{ij}-p\delta_{ij} \tag{9.7.294}$$

Presently, we will introduce the operators of the vector analysis in order to have a more general expression. In this way, we can adapt the formulation to any coordinate system (Cartesian, cylindrical, spherical, etc.) which will facilitate the solving of practical problems.

We have seen that for a solid we had:

$$\begin{aligned}\gamma_{xy}&=2\varepsilon_{xy}=\partial_y u+\partial_x v\\ \gamma_{xz}&=2\varepsilon_{xz}=\partial_z u+\partial_x w\\ \gamma_{yz}&=2\varepsilon_{yz}=\partial_z v+\partial_y w\end{aligned} \tag{9.7.295}$$

We will determine these equations in an index form by always considering displacements per unit of time (velocities).

$$\dot{\varepsilon}_{ij}=\frac{1}{2}(\partial_{x^j}v_i+\partial_{x^i}v_j) \tag{9.7.296}$$

such that $i,j=\{1,2,3\}$ and that:

$$1\rightarrow x\qquad x^1=x\qquad 2\rightarrow y\qquad x^2=y\qquad 3\rightarrow z\qquad x^3=z \tag{9.7.297}$$

For $i=j=1$, we have therefore:

$$\dot{\varepsilon}_{11}=\frac{1}{2}(\partial_{x^1}v_1+\partial_{x^1}v_1) \tag{9.7.298}$$

or:

$$\dot{\varepsilon}_{xx}=\partial_x v_x \tag{9.7.299}$$

$$\begin{gathered}\dot{\varepsilon}_{xx}=\partial_x v_x\qquad\dot{\varepsilon}_{yy}=\partial_y v_y\qquad\dot{\varepsilon}_{zz}=\partial_z v_z\\ \dot{\varepsilon}_{xy}=\frac{1}{2}(\partial_y v_x+\partial_x v_y)\qquad\dot{\varepsilon}_{xz}=\frac{1}{2}(\partial_z v_x+\partial_x v_z)\qquad\dot{\varepsilon}_{yz}=\frac{1}{2}(\partial_z v_y+\partial_y v_z)\end{gathered} \tag{9.7.300}$$

By doing the sum of the terms of the normal deformations rate we get:

$$\dot{\varepsilon}_{xx}+\dot{\varepsilon}_{yy}+\dot{\varepsilon}_{zz}=\partial_x v_x+\partial_y v_y+\partial_z v_z \tag{9.7.301}$$

But, the tools of Vector Calculus allow us to write:

$$\dot{\varepsilon}_{xx}+\dot{\varepsilon}_{yy}+\dot{\varepsilon}_{zz}=\partial_x v_x+\partial_y v_y+\partial_z v_z=\vec{\nabla}\circ\vec{v} \tag{9.7.302}$$

For a fluid, we will then have by analogy:

$$\theta_{11}+\theta_{22}+\theta_{33}=\vec{\nabla}\circ\vec{v} \tag{9.7.303}$$

The general dynamic equation of stresses will then be written in the following form of a Newtonian fluid (under small deformations):

$$\boxed{P_{ij}=2\mu_d\theta_{ij}-\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})\delta_{ij}-p\delta_{ij}} \tag{9.7.304}$$

This stress tensors is written by some teachers and textbooks authors as following (this notion is a little bit dangerous but it can be justified in the context of an in-deep study of fluids dynamics):

$$\sigma=-pI+\lambda(\vec{\nabla}\circ\vec{v})I+2\mu D \tag{9.7.305}$$

or also to differentiate vector and tensor:

$$\underline{\underline{\sigma}}=-p\underline{\underline{I}}+\lambda(\underline{\nabla}\circ\underline{v})\underline{\underline{I}}+2\mu\underline{\underline{D}} \tag{9.7.306}$$

If the normal constraints are negligible (incompressible fluid) the second term simplifies and we have then (relation that we will use in the section of Marine & Weather Engineering):

$$\underline{\underline{\sigma}}=-p\underline{\underline{I}}+2\mu\underline{\underline{D}} \tag{9.7.307}$$

It is now useful to go back in a developed form for the preceding equation, remembering that (see above):

$$\begin{aligned}P_{xx}&=-p-\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})+2\mu_d\partial_x v_x\\P_{yy}&=-p-\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})+2\mu_d\partial_y v_y\\P_{zz}&=-p-\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})+2\mu_d\partial_z v_z\end{aligned} \tag{9.7.308}$$

$$\begin{aligned}P_{xy}&=\mu_d(\partial_x v_x+\partial_x v_y)\\P_{xz}&=\mu_d(\partial_z v_x+\partial_x v_z)\\P_{yz}&=\mu_d(\partial_z y+\partial_y v_z)\end{aligned}$$

Let us now write the system of Newton equations (sums of dynamic internal and external constraints to a volume element of a fluid) which is:

$$\frac{F_T}{V}=\frac{F_{\text{int}}}{V}+\frac{F_{\text{ext}}}{V}=\rho f_i+\frac{\partial}{\partial x_i}\sum_{j=1}^{3}P_{ij} \tag{9.7.309}$$

where:

- $\dfrac{\partial}{\partial x_i}\sum_{j=1}^{3}P_{ij}$ is the sum of external forces by unit volume
- f_i is the traditional (unfortunate ...) notation of the mass acceleration in $[\mathrm{m}\cdot\mathrm{s}^{-2}]$
- ρ is the fluid density

The previous relation can be rewritten in vector form:

$$\rho \mathrm{d}_t\vec{v}=\vec{\nabla}(\vec{\sigma})+\rho\vec{f} \tag{9.7.310}$$

with obviously using tensor summation convention:

$$\vec{\nabla}(\vec{\sigma})_i=(\mathrm{div}\vec{\sigma})_i=\frac{\partial\sigma_{ij}}{\partial x_j}=\frac{\partial P_{ij}}{\partial x_j} \tag{9.7.311}$$

Then we have:

$$\begin{aligned}\rho\mathrm{d}_t v_x&=\partial_x P_{xx}+\partial_y P_{xy}+\partial_z P_{xz}+\rho f_x\\ \rho\mathrm{d}_t v_y&=\partial_x P_{yx}+\partial_y P_{yy}+\partial_z P_{yz}+\rho f_y\\ \rho\mathrm{d}_t v_z&=\partial_x P_{zx}+\partial_z P_{zz}+\partial_z P_{zz}+\rho f_z\end{aligned} \tag{9.7.312}$$

By introducing the expressions of P_{ij} obtained in the above relation, we arrive at the equations:

$$\begin{aligned}\rho\mathrm{d}_t v_x&=-\partial_x p-\partial_x\left(\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})-2\mu_d\partial_x v_x\right)+\partial_y\left[\mu_d\left(\partial_y v_x+\partial_x v_y\right)\right]+\partial_z\left[\mu_d\left(\partial_z v_x+\partial_x v_z\right)\right]+\rho f_x\\ \rho\mathrm{d}_t v_y&=\partial_x\left[\mu_d\left(\partial_y v_x+\partial_x v_y\right)\right]-\partial_y p-\partial_y\left(\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})-2\mu_d\partial_y v_y\right)+\partial_z\left[\mu_d\left(\partial_z v_y+\partial_y v_z\right)\right]+\rho f_y\\ \rho\mathrm{d}_t v_z&=\partial_x\left[\mu_d\left(\partial_z v_x+\partial_x v_z\right)\right]+\partial_y\left[\mu_d(\partial_z v_y+\partial_y v_z))\right]-\partial_z p-\partial_z\left(\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})-2\mu_d\partial_d\partial_z v_z\right)+\rho f_z\end{aligned} \tag{9.7.313}$$

These are the "Navier-Stokes equations of the dynamics of Newtonian fluids" for small deformations. There opne condensed forms which we shall now proceed to determine!

By taking Navier-Stokes's first equation and expanding it, it comes:

$$\begin{aligned}\rho\mathrm{d}_t v_x&=-\partial_x p-\partial_x\left(\frac{2}{3}\mu_d(\vec{\nabla}\circ\vec{v})-2\mu_d\partial_x v_x\right)+\partial_y\left[\mu_d\left(\partial_y v_x+\partial_x v_y\right)\right]+\partial_z\left[\mu_d\left(\partial_z v_x+\partial_x v_z\right)\right]+\rho f_x\\ &=-\partial_x p-\frac{2}{3}\mu_d\partial_x(\vec{\nabla}\circ\vec{v})+2\mu_d\partial_x^2 v_x+\mu_d\partial_y^2 v_x+\mu_d\partial_{yx}^2 v_y+\mu_d\partial_z^2 v_x+\mu_d\partial_{zx}^2 v_z+\rho f_x\\ &=-\partial_x p-\frac{2}{3}\mu\partial_x(\vec{\nabla}\circ\vec{v})+\underbrace{\underline{\mu_d\partial_x^2 v_x}+\underline{\underline{\mu_d\partial_y^2 v_x}}}_{2\mu_d\partial_x^2 v_x}+\underline{\underline{\mu_d\partial_y^2 v_x}}+\underline{\mu_d\partial_y^2 v_x}+\underline{\mu_d\partial_{yx}^2 v_y}+\underline{\underline{\mu_d\partial_z^2 v_x}}+\rho f_x\\ &=-\partial_x p-\frac{2}{3}\mu_d\partial_x(\vec{\nabla}\circ\vec{v})+\mu_d(\partial_x^2 v_x+\partial_{yx}^2 v_y+\partial_{zx}^2 v_z)+\mu_d(\partial_x^2 v_x+\partial_y^2 v_x+\partial_z^2 v_x)+\rho f_x\end{aligned} \tag{9.7.314}$$

As:

$$\partial_x^2 v_x+\partial_{yx}^2 v_y+\partial_{zx}^2 v_z=\partial(\partial_x v_x+\partial_y v_y+\partial_z v_z)=\partial_x(\vec{\nabla}\circ\vec{v}) \tag{9.7.315}$$

and that:

$$\partial_x^2 v_x + \partial_y^2 v_x + \partial_z^2 v_x = \vec{\nabla} \circ (\vec{\nabla}(v_x)) \tag{9.7.316}$$

We get:

$$\rho \mathrm{d}_t v_x = -\partial_x p - \frac{2}{3}\mu_d \partial_x (\vec{\nabla} \circ \vec{v}) + \mu_d \partial_x (\vec{\nabla} \circ \vec{v}) + \mu_d \vec{\nabla} \circ (\vec{\nabla}(v_x)) + \rho f_x \tag{9.7.317}$$

Simplifying, it comes therefore:

$$\rho \mathrm{d}_t v_x = -\partial_x p + \frac{1}{3}\mu_d \partial_x (\vec{\nabla} \circ \vec{v}) + \mu_d \vec{\nabla} \circ (\vec{\nabla}(v_x)) + \rho f_x \tag{9.7.318}$$

By operating in the same way for the other two components, we can reduce the system of Navier-Stokes equations to a single vector equation:

$$\rho \mathrm{d}_t \vec{v} = -\vec{\nabla} p + \frac{1}{3}\mu_d \vec{\nabla}(\vec{\nabla} \circ \vec{v}) + \mu_d \vec{\nabla} \circ (\vec{\nabla} \vec{v}) + \rho \vec{f} \tag{9.7.319}$$

As (see section Vector Calculus page 1903 and page 1911) the vector Laplacian is given by (recalling the different existing notations):

$$\Delta \vec{v} = \vec{\nabla}^2 \vec{v} = \vec{\nabla} \circ (\vec{\nabla} \vec{v}) = \vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \vec{\nabla} \times (\vec{\nabla} \times \vec{v}) \tag{9.7.320}$$

We have:

$$\rho \mathrm{d}_t \vec{v} = -\vec{\nabla} p + \frac{1}{3}\mu_d \vec{\nabla}(\vec{\nabla} \circ \vec{v}) + \mu_d \left[\vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \vec{\nabla} \times (\vec{\nabla} \times \vec{v})\right] + \rho \vec{f} \tag{9.7.321}$$

Thus finally:

$$\rho_{\mathrm{d}} \vec{v} = -\vec{\nabla} p + \frac{4}{3}\vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \mu_d \vec{\nabla} \times (\vec{\nabla} \times \vec{v}) + \rho \vec{f} \tag{9.7.322}$$

Remark

We can also sometimes find in the literature an equation containing a second viscosity ${\mu'}_d$, whereas μ_d only manifests itself rigorously during pure shearing according to our hypotheses, ${\mu'}_d$ appears during an omnidirectional compression accompanied by a variation of density.

The preceding equation is then written:

$$\boxed{\rho_{\mathrm{d}} \vec{v} = -\vec{\nabla} p + \frac{4}{3}(\mu_d + {\mu'}_d)\vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \mu_d \vec{\nabla} \times (\vec{\nabla} \times \vec{v}) + \rho \vec{f}} \tag{9.7.323}$$

This is the "Navier-Stokes equation" (still for Newtonian fluids in small deformations) or also named "equation of motion for a Newtonian fluid".

9.7.2.4.1 Incompressible flow

In fluid mechanics or more generally Continuum Mechanics, an "incompressible flow" or "isochoric flow" refers to a flow in which the material density is constant within a fluid parcel an infinitesimal volume that moves with the flow velocity. An equivalent statement that implies incompressibility is that the divergence of the flow velocity is zero (see the derivation below, which illustrates why these conditions are equivalent).

Incompressible flow does not imply that the fluid itself is incompressible. It is shown in the derivation below that (under the right conditions) even compressible fluids can – to a good approximation – be modelled as an incompressible flow. Incompressible flow implies that the density remains constant within a parcel of fluid that moves with the flow velocity.

In an incompressible fluid, we have by definition $\rho=c^{te}$. The conservation equation which is (see section Thermodynamics page 3683):

$$\partial_t\rho+\vec{\nabla}\circ(\rho\vec{v})=0 \tag{9.7.324}$$

is then written:

$$\rho\vec{\nabla}\circ\vec{v}=0 \tag{9.7.325}$$

Therefore the divergence of the velocity field is zero:

$$\vec{\nabla}\circ\vec{v}=0 \tag{9.7.326}$$

The Navier-Stokes equation in the form:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\frac{1}{3}\mu_d\vec{\nabla}(\vec{\nabla}\circ\vec{v})+\mu_d\vec{\nabla}\circ(\vec{\nabla}\vec{v})+\rho\vec{f} \tag{9.7.327}$$

is then written:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\mu_d\vec{\nabla}\circ(\vec{\nabla}\vec{v})+\rho\vec{f} \tag{9.7.328}$$

or differently using the traditional notation of the Laplacian of a vector field:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\mu_d\vec{\nabla}^2\vec{v}+\rho\vec{f} \tag{9.7.329}$$

If, moreover the viscosity μ_d is negligible, we have for a perfect fluid:

$$\boxed{\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\rho\vec{f}} \tag{9.7.330}$$

This equation is named the "Euler equation of the 1st form" or "local equation of the balance conservation of the momentum". We will reuse this relation as part of our study of gravity waves in the section of Weather & Marine Engineering and also in the section of Cosmology to study the Einstein Universe models! When $\vec{v}=\vec{0}$ we have what is commonly named an "hydrostatic balance".

Remark

It was proved in 11996 (holocene calendar) by Vladimir Scheffer (but the demonstration is horribly complex and comprehensible only by some people on the planet) that the Euler equation in the plan allows a spontaneous creation of energy! So an energy creation from nothing! A year later another mathematician presents a new proof of the same result. A few years later, two young mathematicians proved that it was useless to impose a criterion to the solutions to avoid this paradox ...

There exists a second form of the Euler equation in the framework of an incompressible fluid and of negligible viscosity which we will immediately determine (often used in industry):

If $\vec{v}=f(x,y,z,t)$ we can write:

$$\mathrm{d}_t\vec{v}=\frac{\partial\vec{v}}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial t} \tag{9.7.331}$$

This can also be written:

$$\begin{aligned}\mathrm{d}_t\vec{v}&=(\partial_x\vec{v})v_x+(\partial_y\vec{v})v_y+(\partial_z\vec{v})v_z+\partial_t\vec{v}\\&=\left[\partial_x(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})\right]v_x+\left[\partial_y(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})\right]v_y+\left[\partial_z(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})\right]v_z+\partial_t\vec{v}\\&=[v_x\partial_x v_x]\vec{i}+[v_x\partial_x v_y]\vec{j}+[v_x\partial_x v_z]\vec{k}+[v_y\partial_y v_x]\vec{i}+[v_y\partial_y v_y]\vec{j}+[v_y\partial_y v_z]\vec{k}+[v_z\partial_z v_x]\vec{i}\\&\quad+[v_z\partial_z v_y]\vec{j}+[v_z\partial_z v_z]\vec{k}+\partial_t\vec{v}\end{aligned} \tag{9.7.332}$$

What is also written:

$$(v_x\partial_x+v_y\partial_y+v_z\partial_z)(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})+\partial_t\vec{v} \tag{9.7.333}$$

The first factor can be considered as the following scalar product:

$$(v_x\partial_x+v_y\partial_y+v_z\partial_z)=\left[\underbrace{(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})}_{=\vec{v}}\underbrace{(\partial_x\vec{i}+\partial_y\vec{j}+\partial_z\vec{k})}_{\vec{\nabla}}\right]=\vec{v}\circ\vec{\nabla} \tag{9.7.334}$$

Thus:

$$\mathrm{d}_t\vec{v}=(v_x\partial_x+v_y\partial_y+v_z\partial_z)(v_x\vec{i}+v_y\vec{j}+v_z\vec{k})+\partial_t\vec{v}=(\vec{v}\circ\vec{\nabla})\vec{v}+\partial_t\vec{v} \tag{9.7.335}$$

The "material derivative" (there are many other names for the material derivative[33]) can then take the following condensed form (we thus find the same result as in our study of the second generalized Newton force proved in the section of Classical Mechanics!!!):

$$\mathrm{d}_t\vec{v}=\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v} \tag{9.7.336}$$

That is often written in text books:

$$\boxed{\frac{D\vec{v}}{Dt}=\frac{\partial\vec{v}}{\partial t}+\vec{v}\vec{\nabla}\circ\vec{v}} \tag{9.7.337}$$

where:

---

[33] advective derivative, convective derivative, derivative following the motion, hydrodynamic derivative, Lagrangian derivative, Lagrangian acceleration, particle derivative, substantial derivative, substantive derivative, Stokes derivative, total derivative, ...

- $\partial\vec{v}/\partial t$ is the "Eulerian derivative". That is the rate of change at a fixed point.
- $\vec{\nabla}\circ\vec{v}$ is the "advection term". Advection is the transport of a scalar or vectorial quantity preserved by a vector field. An example is the transport of polluting matter by the flow of a river. In meteorology and oceanography, advection refers mainly to the horizontal transport of certain properties by the fluids considered, including transport by wind or currents: advection of water vapor, heat, salinity, etc.
- $\vec{v}\vec{\nabla}\circ\vec{v}$ is the "convective acceleration". Convective is the acceleration defined as the rate of change of velocity due to the change of position of fluid particles in a fluid flow.

If the material derivative is zero then the field is conserved following the motion and the local rate of change is entirely due to advection.

Remark

The x component of the material derivative is therefore (we will use this again in the section of Marine & Weather Engineering):

$$\mathrm{d}_t v_x=\partial_t v_x+v_x\partial_x v_x+v_y\partial_y v_x+v_z\partial_z v_x \tag{9.7.338}$$

what some experts in the field generally note for any component:

$$\frac{D}{Dt}=\partial_t+v_x\partial_x+v_y\partial_y+v_z\partial_z=\partial_t+\vec{v}\circ\vec{\nabla} \tag{9.7.339}$$

The Euler equation of the first form:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\rho\vec{f} \tag{9.7.340}$$

becomes taking into account the material derivative:

$$\rho\left[\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}\right]=\rho\vec{f}-\vec{\nabla}p \tag{9.7.341}$$

Remark

Notice that if we didn't neglect the viscosity μ_d we would simply have:

$$\rho\left[\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}\right]=\rho\vec{f}+\mu_d\vec{\nabla}^2\vec{v}-\vec{\nabla}p \tag{9.7.342}$$

This is a very common form of the Navier-Stokes equation that we can also found in plenty of textbooks!

Or (common form in the literature):

$$\partial_t\vec{v}+(\vec{v}\circ\vec{\Delta})\vec{v}=-\frac{1}{\rho}\vec{\nabla}p+\vec{f} \tag{9.7.343}$$

We have proved in the section of Vector Calculus (see 1911) that:

$$\vec{\nabla}(\vec{u}\circ\vec{v})=\vec{u}\times(\vec{\nabla}\times\vec{v})+\vec{v}\times(\vec{\nabla}\times\vec{u})+(\vec{u}\circ\vec{\nabla})\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{u} \tag{9.7.344}$$

If we put $\vec{u}=\vec{v}$, we have:

$$\vec{\nabla}\|\vec{v}\|^2=\vec{\nabla}v^2=2\vec{v}\times(\vec{\nabla}\times\vec{v})+2(\vec{v}\circ\nabla)\vec{v} \tag{9.7.345}$$

Therefore:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2-\vec{v}\times(\vec{\nabla}\times\vec{v}) \tag{9.7.346}$$

Notice that we can therefore rewrite the acceleration (material derivative):

$$\frac{D\vec{v}}{Dt}=\frac{\partial\vec{v}}{\partial t}+\vec{v}\vec{\nabla}\circ\vec{v} \tag{9.7.347}$$

as:

$$\frac{D\vec{v}}{Dt}=\frac{\partial\vec{v}}{\partial t}+\frac{1}{2}\vec{\nabla}v^2-\vec{v}\times(\vec{\nabla}\times\vec{v}) \tag{9.7.348}$$

as we will see and explain later the rotational of the vector speed is related to the concept of "vorticity".

Finally, we get a new equation named the "Euler equation of the 2nd form" which is written:

$$\boxed{\rho\partial_t\vec{v}=\rho\vec{f}-\vec{\nabla}p-\frac{\rho}{2}\vec{\nabla}v^2+\rho\vec{v}\times(\vec{\nabla}\times\vec{v})} \tag{9.7.349}$$

Also sometimes rearranged as:

$$\rho\partial_t\vec{v}+\rho\left(\frac{1}{2}\vec{\nabla}v^2-\vec{v}\times(\vec{\nabla}\times\vec{v})\right)-\rho\vec{f}=\vec{0} \tag{9.7.350}$$

Although the two Euler equations of are very important, there exists a variation form very useful in meteorology which we will now determine.

We always rely on the flow of an incompressible and non-viscous fluid, but whose volumic forces are derived this time from a potential $\vec{f}=-\vec{\nabla}U$ where U is typicall the gravitional potentiel for example.

In this case, we use the Euler equation in its first form:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\rho\vec{f} \tag{9.7.351}$$

Since the volumic forces $\vec{f}$ derive from a potential U, we have:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}(p+\rho U) \tag{9.7.352}$$

Let us recall the relation (see section Vector Calculus page 1911):

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2-\vec{v}\times(\vec{\nabla}\times\vec{v}) \tag{9.7.353}$$

Given $\vec{\nabla}\times\vec{v}$ be a vector $\vec{A}$, it comes:

$$-\vec{v}\times\vec{A}=\vec{A}\times\vec{v} \tag{9.7.354}$$

Therefore:

$$-\vec{v}\times(\vec{\nabla}\times\vec{v})=(\vec{\nabla}\times\vec{v})\times\vec{v} \tag{9.7.355}$$

so we can also write:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2+(\vec{\nabla}\times\vec{v})\times\vec{v} \tag{9.7.356}$$

By taking up the material derivative[34]:

$$\mathrm{d}_t\vec{v}=\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v} \tag{9.7.357}$$

the equation:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}(p+\rho U) \tag{9.7.358}$$

then becomes:

$$\rho\mathrm{d}_t\vec{v}=\rho\left[\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}\right]=-\vec{\nabla}(p+\rho U) \tag{9.7.359}$$

and using:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2+(\vec{\nabla}\times\vec{v})\times\vec{v} \tag{9.7.360}$$

the latter becomes:

$$\rho\partial_t\vec{v}+\rho\left[\frac{1}{2}v^2+(\vec{\nabla}\times\vec{v})\times\vec{v}\right]=-\vec{\nabla}(p+\rho U) \tag{9.7.361}$$

and since:

$$\frac{1}{2}\vec{\nabla}v^2=\vec{\nabla}\left(\frac{v^2}{2}\right) \tag{9.7.362}$$

we can finally write:

$$\rho\partial_t\vec{v}+\rho\left[\frac{1}{2}\vec{\nabla}v^2+(\vec{\nabla}\times\vec{v})\times\vec{v}\right]+\vec{\nabla}(p+\rho U)=\vec{0} \tag{9.7.363}$$

Rearranging and simplifying, we get:

$$\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+(\vec{\nabla}\times\vec{v})\times\vec{v}=\vec{0} \tag{9.7.364}$$

✍**Example:**

E1. Let us consider a bucket filled with a Newtonian fluid rotating at an angular velocity ω.

---

[34] Also sometimes, for recall, denoted $\frac{\mathrm{D}\vec{v}}{\mathrm{D}t}=\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}$

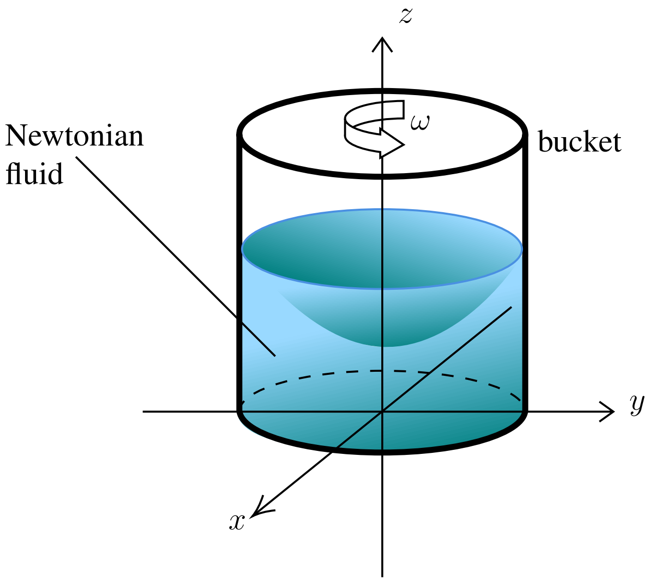


Figure 9.245: Rotating bucket

Given incompressibility assumption and steady flow !

Consider Euler's equation in a uniform constant gravitational field (see page 3830):

$$\frac{\partial \vec{v}}{\partial t}+(\vec{v}\circ\vec{\nabla})\vec{v}=-\vec{\nabla}\frac{p}{\rho}+\vec{g} \tag{9.7.365}$$

As the flow is steady (i.e. $\partial\vec{v}/\partial t=\vec{0}$), the latter reduces to:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=-\vec{\nabla}\frac{p}{\rho}+\vec{g} \tag{9.7.366}$$

As the fluid is rotating circularly following the axis of symmetry z of the configuration we have:

$$\begin{aligned} v_x&=y\omega\\ v_y&=x\omega\\ v_z&=0 \end{aligned} \tag{9.7.367}$$

Where we are assuming obvioulsy the z-axis to be the axis of rotation. Hence:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\left(\begin{pmatrix} x\omega\\ y\omega\\ 0\end{pmatrix}\circ\begin{pmatrix}\partial_x\\ \partial_y\\ \partial_z\end{pmatrix}\right)\begin{pmatrix} x\omega\\ y\omega\\ 0\end{pmatrix}=\begin{pmatrix} x\omega^2\\ y\omega^2\\ 0\end{pmatrix} \tag{9.7.368}$$

Upon substitution of each component individually into Euler's equation above, we arrive at the centripetal acceleration in terms of surface pressure (assuming an inertial frame):

$$\begin{aligned} x\omega^2&=-\frac{1}{\rho}\frac{\partial p}{\partial x}\\ y\omega^2&=-\frac{1}{\rho}\frac{\partial p}{\partial y}\\ 0&=-\frac{1}{\rho}\frac{\partial p}{\partial z}+g \end{aligned} \tag{9.7.369}$$

Now, we evaluate the integral of these expressions:

$$\begin{aligned}\frac{x^2\omega^2}{2}&=\frac{p}{\rho}\\ \frac{y^2\omega^2}{2}&=\frac{p}{\rho}\\ \frac{p}{\rho}&=-gz\end{aligned} \tag{9.7.370}$$

We know that the general solution is the sum of all particular solution. We then have:

$$\frac{p}{\rho}=\frac{\omega^2\left(x^2+y^2\right)}{2}-gz+c^{te} \tag{9.7.371}$$

Indeed we can check that's correct:

$$\begin{aligned}x\omega^2&=-\frac{1}{\rho}\frac{\partial p}{\partial x}=-\frac{1}{\rho}\frac{\partial\left(\rho\frac{\omega^2\left(x^2+y^2\right)}{2}-\rho gz+c^{te}\right)}{\partial x}\\ y\omega^2&=-\frac{1}{\rho}\frac{\partial\left(\rho\frac{\omega^2\left(x^2+y^2\right)}{2}-\rho gz+c^{te}\right)}{\partial y}\\ 0&=-\frac{1}{\rho}\frac{\partial\left(\rho\frac{\omega^2\left(x^2+y^2\right)}{2}-\rho gz+c^{te}\right)}{\partial z}+g\end{aligned} \tag{9.7.372}$$

Given $p=$ constant at a free surface (we can then choose $c^{te}=p/\rho$ so that they cancel), i.e. at the interface between the liquid and the gas, and solving for z:

$$\boxed{z=\frac{\omega^2\left(x^2+y^2\right)}{2g}} \tag{9.7.373}$$

The surface adopts the shape of a paraboloid! This is the proof water can be curved by a force like the centripetal acceleration (like the water/seas/ocean can be curved by gravity)!

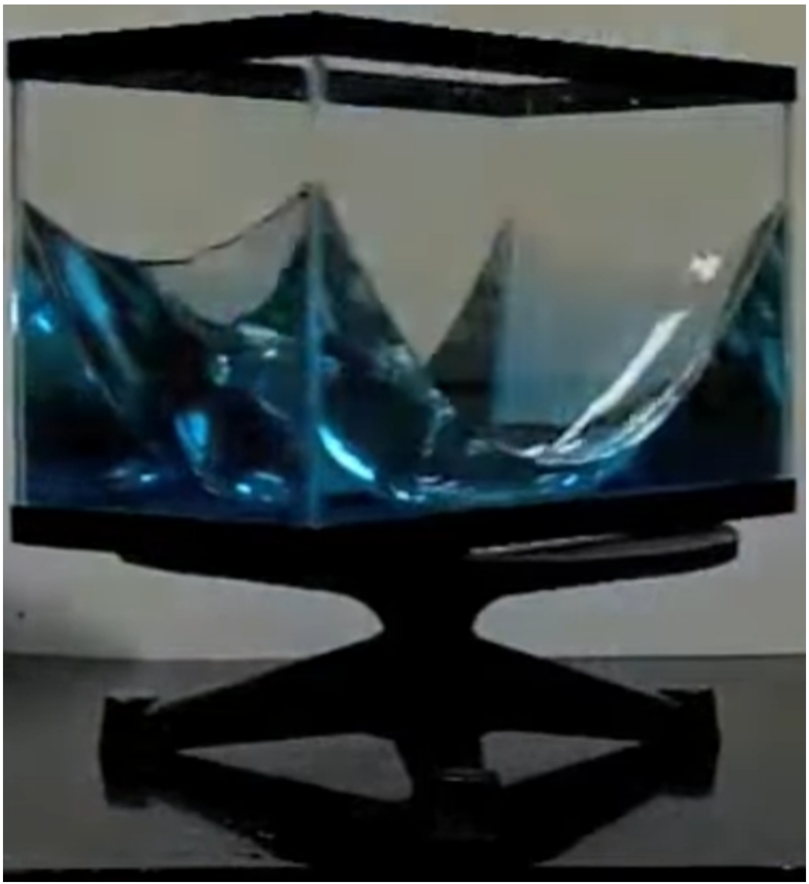

Figure 9.246: **Rotating bucket experiment (source: YouTube, author: Dan Russell)**

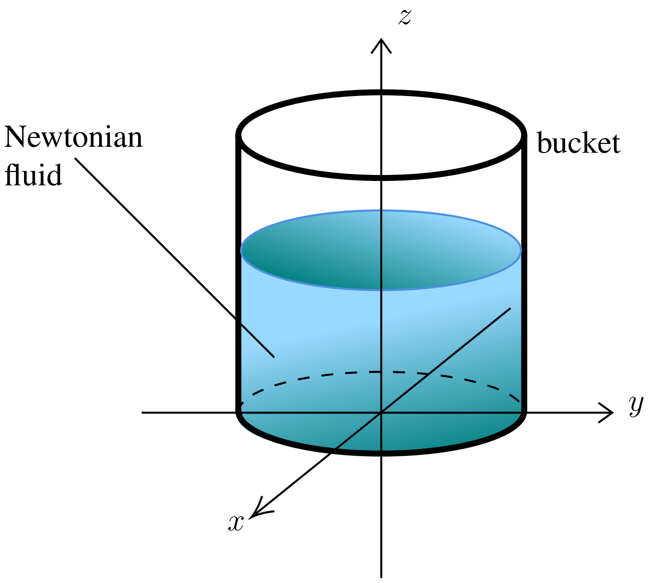
Notice that if $\omega=0$ we have $z=0$ for all (x,y), that means the liquid is obviously at the same level and therefore flat:



Let us now denote z_0 the height between the bottom of the parabola and the bottom of the bucket and let us denote $x^2+y^2=r^2$ the radius distance from the vertical axis of rotation of the bucket.

Therefore:

$$z=z_0+\frac{\omega^2r^2}{2g} \tag{9.7.374}$$

Now let us denote H the height of the fluid at rest (when $\omega=0$). Therefore obviously the total mass of the fluid in the cylinder is simply given by:

$$m=\rho\pi R^2H \tag{9.7.375}$$

where R is the radius of the bucket. When $\omega\neq 0$ we have using the shell method:

$$\begin{aligned}m&=\rho\int\limits_0^R(2\pi r)z\mathrm{d}r=\rho\int\limits_0^R(2\pi r)\left[z_0+\frac{\omega^2r^2}{2g}\right]\mathrm{d}r\\&=\rho(2\pi)\int\limits_0^R\left(z_0r+\frac{\omega^2r^3}{2g}\right)\mathrm{d}r=2\pi\rho\left(\frac{z_0R^2}{2}+\frac{\omega^2R^4}{8g}\right)\end{aligned} \tag{9.7.376}$$

Equating the two masses (the non-spinning case and the spinning case), we get:

$$m=\rho\pi R^2H=2\pi\rho\left(\frac{z_0R^2}{2}+\frac{\omega^2R^4}{8g}\right) \tag{9.7.377}$$

Hence after simplification and rearrangement:

$$H=z_0+\frac{\omega^2R^2}{4g} \tag{9.7.378}$$

So finally at the center of the container:

$$z_0=H-\frac{\omega^2R^2}{4g} \tag{9.7.379}$$

We can seek for the maximum ω such that $z_0=0$. Therefore we get immediately:

$$\omega_{\text{max}}=\frac{2}{R}\sqrt{gH} \tag{9.7.380}$$

9.7.2.4.1.1 Vorticity and vorticity equation

Let us generalize this last relation by making emerge possible rotations. For this we know that (see section Classical Mechancis page 3280):

$$\vec{v}=\vec{\omega}\times\vec{r} \tag{9.7.381}$$

therefore:

$$\vec{\nabla}\times\vec{v}=\vec{\nabla}\times(\vec{\omega}\times\vec{r}) \tag{9.7.382}$$

By writing the vector product $\vec{\omega}\times\vec{r}$ in developed form, we have:

$$\vec{\nabla}\times\left[(\omega_y z-\omega_z y)\vec{i}+(\omega_z x-\omega_x z)\vec{j}+(\omega_x y-\omega_y k)\vec{k}\right] \tag{9.7.383}$$

Which gives:

$$\begin{aligned}\vec{\nabla}\times\vec{v}=&\,\partial_y(\omega_x y-\omega_y x)\vec{i}+\partial_x(\omega_z x-\omega_x z)\vec{k}+\partial_z(\omega_y z-\omega_z y)\vec{j}\\&-\partial_y(\omega_y z-\omega_z y)\vec{k}-\partial_z(\omega_z x-\omega_x z)\vec{i}-\partial_x(\omega_x y-\omega_y x)\vec{j}\end{aligned} \tag{9.7.384}$$

Let us suppose that $\vec{\omega}$ is a constant angular velocity vector, we then have:

$$\vec{\nabla}\times\vec{v}=\omega_x\vec{i}+\omega_z\vec{k}+\omega_y\vec{j}+\omega_z\vec{k}+\omega_x\vec{i}+\omega_y\vec{j}=2(\omega_x\vec{i}+\omega_y\vec{j}+\omega_z\vec{k})=2\vec{\omega} \tag{9.7.385}$$

Definition (#9.7.474): We say that we have a "vortex flow" if the rotation of the velocity field is non-zero:

$$\vec{\nabla}\times\vec{v}\neq\vec{0} \tag{9.7.386}$$

everywhere or at certain points. We also define from the prior-previous relationship the "vorticity" by:

$$\boxed{\vec{\omega}=\frac{1}{2}\vec{\nabla}\times\vec{v}} \tag{9.7.387}$$

Notice that in the special case of a 2-D flow:

$$\vec{u}(x,y,t)=\begin{pmatrix}u(x,y,t)\\v(x,y,t)\\0\end{pmatrix} \tag{9.7.388}$$

the vorticity:

$$\vec{\omega}=\vec{\nabla}\times\vec{u}=\begin{pmatrix}0\\0\\\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\end{pmatrix} \tag{9.7.389}$$

is perpendicular to the plane of motion, its magnitude is:

$$\omega=\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y} \tag{9.7.390}$$

Caution! At this point, we have a small problem with conventions... In a huge majority of textbooks (and even Wikipedia) the vorticity is not derived as we did just above but rather just defined! And the most common definition of vorticity is sadly then given by $\vec{\omega}=\vec{\nabla}\times\vec{v}$. So therefore the consequence is that obviously the vorticity is equal twice the value of angular velocity and many textbooks authors have problems explaining this difference of a factor 2. Even worst... all related relation that we will derived later below will always have multiple times a factor 2 that differs with the huge majority of textbooks. That's the problem when there are no ISO standards for everything in physics...

Notice that we have therefore:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2+(\vec{\nabla}\times\vec{v})\times\vec{v}\Leftrightarrow(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2+2\vec{\omega}\times\vec{v} \qquad (9.7.391)$$

Example of partially vortex flow simulation (at some points):

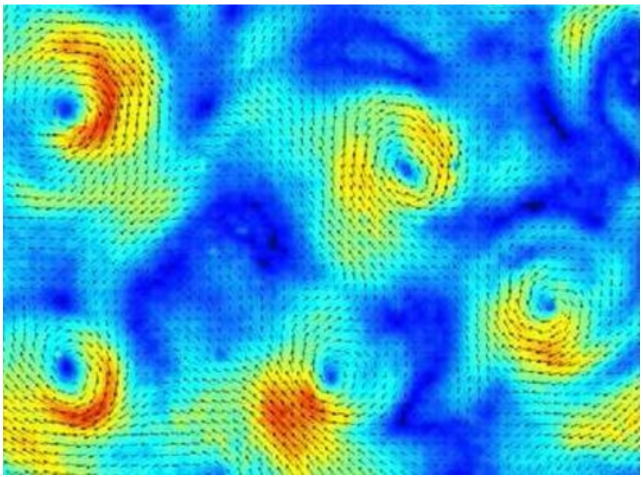


Figure 9.247: Example of a simulated vortex flow

and in real life at large scale levels[35] (Jupiter has also a famous one...):

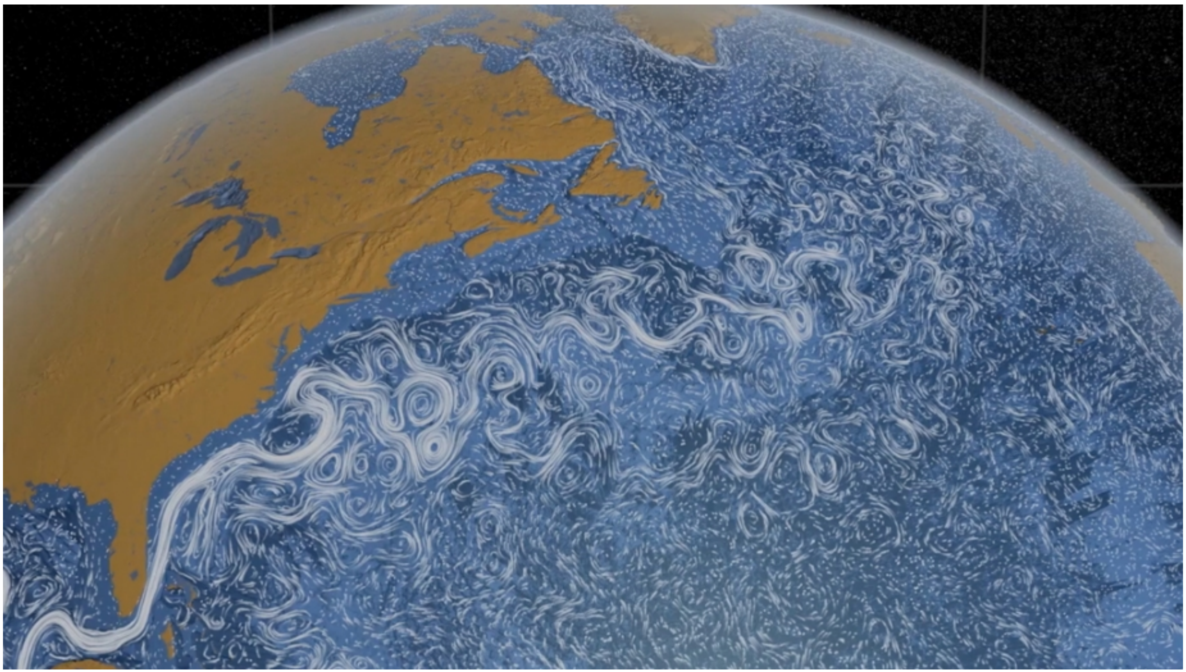

Figure 9.248: Earth currents and vortex between June 12005 to December 12007 (source: NASA/SVS)

---

[35] This a rebuild pic of ocean surface currents between June 12005 (holocene calendar) to December 12007 (holocene calendar) from NASA satellites on our planet. The Pacific carry warm waters across thousands of kilometers at speeds greater than six kilometers per hour; coastal currents like the Agulhas in the Southern Hemisphere move equatorial waters toward Earth's poles; and how thousands of other ocean currents are confined to particular regions and form slow-moving, circular pools.

✍**Examples:**

E1. Free vortex flow is one in which the fluid mass rotates without any external impressed contact force. The whole fluid mass rotates either due to fluid pressure itself or the gravity or due to rotation previously imparted. The free vortex motion is also named "potential vortex" or "irrotational vortex".

Typical well known practical cases are: flow around a circular bend, a whirlpool in a river, flow of liquid in a centrifugal pump casing after it has left the impeller, flow of water in a turbine casing before it enters the guide vanes, flow of liquid through a hole/outlet provided at the bottom of a shallow vessel (e.g., wash basin, bath tub, etc.).

In free vortex the relation between velocity and radius is obtained by putting the value of external torque equal to zero, or, the time rate change of angular momentum (i.e., moment of momentum) must be zero! That is:

$$\frac{\partial}{\partial t}(mvr)=0$$

Integrating, we get:

$$mvr=c^{te}$$

Since m is constant:

$$mvr=C^{te}$$

where C^{te} is a constant and is known as "strength of vortex". Therefore:

$$v=\frac{C^{te}}{r}\propto\frac{1}{r}$$

ie tangential velocity is inversely proportional to distance r.

Now, if we look at a rotating flow in cylindrical coordinates we know from our study of Differential Operators that:

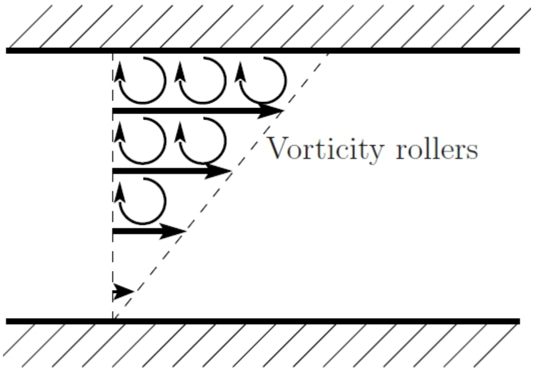
$$\vec{\nabla}\times\vec{v}=\frac{1}{r}\frac{\partial(rv_\theta)}{\partial r}$$

in case of a free vortex we have just seen that $v_\theta\propto 1/r$ and therefore the derivative in the above equation vanishes for a vortex centered at $r=0$. In other words, the vorticity is zero everywhere, i.e. $\vec{\omega}=\vec{0}$.

Although the flow is rotating globally, there is no local rotation. Crossed vanes placed in the flow would move in a circle, but without spinning.

E2. Let us consider again a 2-D flow in a pipe where the flow speed decrease from top to down in proportion to a given constant k:

$$\vec{u}(x,y,t)=\begin{pmatrix}u(x,y,t)\\v(x,y,t)\\0\end{pmatrix}=\begin{pmatrix}ky\\0\\0\end{pmatrix}$$



Therefore we have $\vec{\omega}=(0,0,-k)$. So in this case the vorticity is not a measure of global rotation: a shear flow has no global rotation but a non-zero vorticity!!!

The equation:

$$\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+(\vec{\nabla}\times\vec{v})\times\vec{v}=\vec{0} \tag{9.7.392}$$

is then written:

$$\boxed{\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+2\vec{\omega}\times\vec{v}=\vec{0}} \tag{9.7.393}$$

and sometimes named the "momentum balance equation". We find in this equation, used in meteorology, the Coriolis acceleration that we had determined in the section of Classical Mechanics page 3388!

If the flow is at constant velocity then:

$$\mathrm{d}_t\vec{v}=\vec{0} \tag{9.7.394}$$

and the fluid is then not rotational (non-turbulent):

$$\vec{\omega}\times\vec{v}=\vec{0} \tag{9.7.395}$$

then the above equation reduces to:

$$\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]=\vec{0} \tag{9.7.396}$$

In classical dynamics of the rigid material point (see section Classical Mechanics page 3351), we have shown that in the case of a terrestrial gravitational potential the "geopotential" was given by:

$$U=g(z-z_0)\;[\mathrm{J}\cdot\mathrm{kg}^{-1}] \tag{9.7.397}$$

z being the altitude of a point of the fluid with respect to an reference level z_0. If we take z_0 for the ground level, the prior-previous relation becomes then in the case of a flow then say to be "potential flow":

$$\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+gz\right]=\vec{0} \tag{9.7.398}$$

The term in brackets to satisfy this relationship must be such that:

$$\frac{1}{2}\rho v^2+\rho gz+p=c^{te} \quad (9.7.399)$$

We thus fall back well on Bernoulli's theorem, which confirms our model of Newtonian fluids according to the Navier-Stokes model.

If the flow is inversely a vortex flow, such that:

$$\vec{\nabla}\times\vec{v}=\vec{0} \quad (9.7.400)$$

Now, as we have proved in the section of Vector Calculus, if the rotational of a vector variable is zero, the variable can be expressed as the gradient of a scalar potential! Consequently, in the case of the vortex, the velocity field then derives from a velocity potential:

$$\vec{v}=\vec{\nabla}\varphi \quad (9.7.401)$$

And if in addition the fluid is incompressible, as we saw above:

$$\vec{\nabla}\circ\vec{v}=0 \quad (9.7.402)$$

Then by combining the last two relations it comes (divergence of the gradient):

$$\vec{\nabla}\circ(\vec{\nabla}\circ\vec{v})=0 \quad (9.7.403)$$

Thus explicitly:

$$\frac{\partial^2\varphi}{\partial x^2}+\frac{\partial^2\varphi}{\partial y^2}+\frac{\partial^2\varphi}{\partial z^2}=0 \quad (9.7.404)$$

The potential of the velocities in the case of an uncompressible and non-vortex liquid thus verifies the Laplace's equation:

$$\nabla^2\varphi=0 \qquad \text{or} \qquad \Delta\varphi=0 \quad (9.7.405)$$

Remember that if we didn't neglect the viscosity μ_d we would simply have:

$$\rho\left[\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}\right]=\rho\vec{f}+\mu_d\vec{\nabla}^2\vec{v}-\vec{\nabla}p \quad (9.7.406)$$

and using:

$$(\vec{v}\circ\vec{\nabla})\vec{v}=\frac{1}{2}\vec{\nabla}v^2+2\vec{\omega}\times\vec{v} \quad (9.7.407)$$

This lead us then obviously to:

$$\rho\left[\partial_t\vec{v}+\frac{1}{2}\vec{\nabla}v^2+2\vec{\omega}\times\vec{v}\right]=\rho\vec{f}+\mu_d\vec{\nabla}^2\vec{v}-\vec{\nabla}p \quad (9.7.408)$$

Often rearranged as following:

$$\partial_t\vec{v}-2\vec{v}\times\vec{\omega}=-\vec{\nabla}\left(\frac{1}{2}v^2+\frac{p}{\rho}+\vec{f}\right)+\mu_d\vec{\nabla}^2\vec{v} \quad (9.7.409)$$

and considering a gravitational potential:

$$\partial_t \vec{v} - 2\vec{v} \times \vec{\omega} = -\vec{\nabla}\left(\frac{1}{2}v^2 + \frac{p}{\rho} + g\vec{z}\right) + \mu_d \vec{\nabla}^2 \vec{v} \tag{9.7.410}$$

In the relation above, between the parenthesis, we see the Bernoulli terms. We can now also use this equation to derive Bernoulli's equation and to state the conditions under which it applies!

Suppose then the following conditions:

$$\begin{aligned} \rho &= c^{te} && \text{incompressible fluid} \\ \partial_t \vec{v} &= \vec{0} && \text{steady flow} \\ \mu_d \vec{\nabla}^2 v &= \vec{0} && \text{neglect viscosity} \end{aligned} \tag{9.7.411}$$

Under these conditions the equation above simplifies to:

$$2\vec{v} \times \vec{\omega} = \vec{\nabla}\left(\frac{1}{2}v^2 + \frac{p}{\rho} + g\vec{z}\right) \tag{9.7.412}$$

In the special case where $\vec{\omega} = \frac{1}{2}\vec{\nabla} \times \vec{v}$ is zero everywhere, that is the fluid is not rotating, we have:

$$\vec{0} = \vec{\nabla}\left(\frac{1}{2}v^2 + \frac{p}{\rho} + gz\right) \tag{9.7.413}$$

Therefore:

$$\frac{1}{2}v^2 + \frac{p}{\rho} + gz = c^{te} \tag{9.7.414}$$

and we fall back on Bernoulli's equation!

Notice that $\vec{v} \times \vec{\omega}$, being a cross product, it is always perpendicular to $\vec{v}$, i.e., always zero in the direction of $\vec{v}$. That means we can use Bernoulli's equation only along a streamline!

Now let's go back to (remember $\vec{f} = -\vec{\nabla}U$):

$$\partial_t \vec{v} - 2\vec{v} \times \vec{\omega} = -\vec{\nabla}\left(\frac{1}{2}v^2 + \frac{p}{\rho} + U\right) + \mu_d \vec{\nabla}^2 \vec{v} \tag{9.7.415}$$

to see how the viscosity term may be influenced by $\vec{\omega}$.

For that purpose, remember that we have proved in the section of Vector Calculus at page 1914, that:

$$\vec{\nabla} \times (\vec{\nabla} \times \vec{v}) = \vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \Delta \vec{v} = \vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \vec{\nabla}^2 \vec{v} \tag{9.7.416}$$

Hence:

$$\vec{\nabla}^2 \vec{v} = \vec{\nabla}(\vec{\nabla} \circ \vec{v}) - \vec{\nabla} \times (\vec{\nabla} \times \vec{v}) \tag{9.7.417}$$

If we assume the fluid velocity non divergent (i.e. $\vec{\nabla}\circ\vec{v}=0$), then we get obviously:

$$\vec{\nabla}^2\vec{v}=-\vec{\nabla}\times(\vec{\nabla}\times\vec{v}) \qquad (9.7.418)$$

Using the vorticity relation proven earlier above:

$$\vec{\omega}=\frac{1}{2}\vec{\nabla}\times\vec{v} \qquad (9.7.419)$$

Therefore:

$$\vec{\nabla}^2\vec{v}=-2\vec{\nabla}\times\vec{\omega} \qquad (9.7.420)$$

Hence:

$$\mu_d\vec{\nabla}^2\vec{v}=-2\mu_d\vec{\nabla}\times\vec{\omega} \qquad (9.7.421)$$

From this relation we see that there are no viscous forces where the vorticity $\vec{\omega}$ is zero, or even when $\vec{\omega}$ is constant as in solid body rotation!

With these assumptions and relations we can rewrite:

$$\partial_t\vec{v}-2\vec{v}\times\vec{\omega}=-\vec{\nabla}\left(\frac{1}{2}v^2+\frac{p}{\rho}+U\right)+\mu_d\vec{\nabla}^2\vec{v} \qquad (9.7.422)$$

as following:

$$\partial_t\vec{v}-2\vec{v}\times\vec{\omega}=-\vec{\nabla}\left(\frac{1}{2}v^2+\frac{p}{\rho}+U\right)-2\mu_d\vec{\nabla}\times\vec{\omega} \qquad (9.7.423)$$

Now let us take the curl of both sides of the relation above:

$$\vec{\nabla}\times[\partial_t\vec{v}-2\vec{v}\times\vec{\omega}]=\vec{\nabla}\times\left[-\vec{\nabla}\left(\frac{1}{2}v^2+\frac{p}{\rho}+U\right)-2\mu_d\vec{\nabla}\times\vec{\omega}\right] \qquad (9.7.424)$$

Let us recall that the curl of a gradient is identically zero (vector identity: $\vec{\nabla}\times\vec{\nabla}\cdot U=0$ as proved in the section of Vector Calculus page 1912). Thus the Bernoulli terms all gout out in the above relation:

$$\vec{\nabla}\times\vec{\nabla}\left(\frac{1}{2}v^2+\frac{p}{\rho}+U\right)=0 \qquad (9.7.425)$$

Therefore it reduces to:

$$\vec{\nabla}\times[\partial_t\vec{v}-2\vec{v}\times\vec{\omega}]=-2\mu_d\vec{\nabla}\times\vec{\nabla}\times\vec{\omega} \qquad (9.7.426)$$

Next, we note that because we can interchange the order of partial differentiation, we get:

$$\vec{\nabla}\times\frac{\partial\vec{v}}{\partial t}=\frac{\partial}{\partial t}\left(\vec{\nabla}\times\vec{v}\right)=2\frac{\partial\vec{\omega}}{\partial t} \qquad (9.7.427)$$

Putting it back in the prior-previous relation and simplifying in both sides by the factor 2 we get the "vorticity equation":

$$\boxed{\partial_t\vec{\omega}+\vec{\nabla}\times(\vec{\omega}\times\vec{v})=-\mu_d\vec{\nabla}\times(\vec{\nabla}\times\vec{\omega})} \qquad (9.7.428)$$

This equation is the differential equation for the dynamical behaviour of the vorticity field $\vec{\omega}$. The only restriction is that it applies to constant density fluids. If we wish to work with non constant density fluids we have to go back and work and use a more general formula for the viscous force.

We notice that if $\vec{\omega}=\vec{0}$ everywhere initially, then $\vec{\omega}$ remains zero. Thus, flows that start off irrotational remain so.

Remark

An important simplification we obtained in going to an equation for the vorticity field $\vec{\omega}$ was the elimination of the Bernoulli terms. This removes the pressure and gravitational forces from the equation for $\vec{\omega}$, implying that pressure and gravity have no direct effect on the behaviour of vorticity. We see this result in the case of the motion of a smoke ring. The ring moves in a straight line across a room completely unaffected by gravity (pressure and gravity can have an indirect effect in that they affect the velocity field $\vec{v}$ which appears in the $\vec{\nabla}\times\vec{\omega}\times\vec{v}$ term).

The latter relation can be found in another very common shape if we know the identity:

$$\vec{\nabla}\times\left(\vec{f}\times\vec{g}\right)=\left(\vec{g}\circ\vec{\nabla}\right)\vec{f}-\vec{g}\left(\vec{\nabla}\circ\vec{f}\right)-\left(\vec{f}\circ\vec{\nabla}\right)\vec{g}+\vec{f}\left(\vec{\nabla}\circ\vec{g}\right) \tag{9.7.429}$$

already proved in the section of Vector Calculus page 1912 and we neglect μ_d. Therefore:

$$\partial_t\vec{\omega}+\vec{\nabla}\times(\vec{\omega}\times\vec{v})=\vec{0} \tag{9.7.430}$$

Becomes:

$$\partial_t\vec{\omega}+\left(\vec{v}\circ\vec{\nabla}\right)\vec{\omega}-\vec{v}\left(\vec{\nabla}\circ\vec{\omega}\right)-\left(\vec{\omega}\circ\vec{\nabla}\right)\vec{v}+\vec{\omega}\left(\vec{\nabla}\circ\vec{v}\right)=\vec{0} \tag{9.7.431}$$

For incompressible flows $\vec{\nabla}\circ\vec{v}=0$ and, in addition, $\vec{\nabla}\circ\vec{\omega}=0$ as $\vec{\omega}=\frac{1}{2}\vec{\nabla}\times\vec{v}$. Hence:

$$\partial_t\vec{\omega}+\left(\vec{v}\circ\vec{\nabla}\right)\vec{\omega}-\left(\vec{\omega}\circ\vec{\nabla}\right)\vec{v}=\vec{0} \tag{9.7.432}$$

Rearranging we get the other famous shape of a special case of the vorticity equation:

$$\partial_t\vec{\omega}+\left(\vec{v}\circ\vec{\nabla}\right)\vec{\omega}=\left(\vec{\omega}\circ\vec{\nabla}\right)\vec{v} \tag{9.7.433}$$

And some specialists the introduce the "material derivative of the rotational" as:

$$\boxed{\frac{\mathrm{D}\tilde{\omega}}{\mathrm{D}t}=\partial_t\vec{\omega}+\left(\vec{v}\circ\vec{\nabla}\right)\vec{\omega}=\left(\vec{\omega}\circ\vec{\nabla}\right)\vec{v}} \tag{9.7.434}$$

In a two-dimensional planar flow, $\vec{v}=(u(x,y),v(x,y),0)$, the vector vorticity has only one non-zero component, $\vec{\omega}=(\partial v/\partial x-\partial u/\partial y)\hat{\vec{e}}_z$, so that:

$$(\vec{\omega}\circ\vec{\nabla})\vec{u}=\omega\frac{\mathrm{d}}{\mathrm{d}z}\vec{v}(x,y)=0 \tag{9.7.435}$$

Hence, the vorticity equation, reduces to:

$$\frac{\mathrm{D}\omega_z}{\mathrm{D}t}=\frac{\partial\omega_z}{\partial t}+(\vec{u}\circ\vec{\nabla})\omega_z=0 \tag{9.7.436}$$

shows that the vorticity of a fluid particle remains constant. If, in addition the flow is steady, $\partial\omega_z/\partial t=0$ then the vorticity is constant along streamlines.

9.7.2.4.1.2 Circulation

Consider a closed curve $\mathcal{C}$ in the flow. The circulation around $\mathcal{C}$ is the line integral of the tangential velocity around $\mathcal{C}$:

$$\Gamma=\oint_{\mathcal{C}}\vec{v}\circ\mathrm{d}\vec{l} \qquad (9.7.437)$$

By Stokes theorem, for any surface $\mathcal{S}$ spanning the curve $\mathcal{C}$:

$$\Gamma=\oint_{\mathcal{C}}\vec{v}\circ\mathrm{d}\vec{l}=\int_{\mathcal{S}}(\vec{\nabla}\times\vec{v})\circ\vec{n}\mathrm{d}S=\int_{\mathcal{S}}\omega\cdot\vec{n}\mathrm{d}S \qquad (9.7.438)$$

So, the circulation around $\mathcal{C}$ is equal to the vorticity flux through the surface $\mathcal{S}$: it is the strength of the vortex tube.

9.7.2.4.2 Compressible flow

In this case ρ_0 is a function of the pressure p (case of the "barotropic fluids"). We also consider that the viscosity is negligible. He then comes:

$$\frac{\vec{\nabla}p}{\rho}=\vec{\nabla}\int\frac{\mathrm{d}p}{\rho} \tag{9.7.439}$$

The equation:

$$\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+2\vec{\omega}\times\vec{v}=\vec{0} \tag{9.7.440}$$

is then written:

$$\boxed{\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\int\frac{\mathrm{d}p}{\rho}+U\right]+2\vec{\omega}\times\vec{v}=\vec{0}} \tag{9.7.441}$$

9.7.2.4.3 Static flow

The fluid on which the net force is zero is considered as a "static flow". Means the bulk of fluid moving with constant velocity would be a static fluid. This also includes the stationary fluid. i.e. zero velocity. Non ideal fluids (with viscocity and turbulence present) would never have a flow with constant bulk velocity due to presence of non zero shear forces. But in some cases, like the fluid in a tank moving with constant acceleration is considered as static case with the assumption that the internal motion within the fluid is negligible.

In the static case:

$$\vec{v}=\vec{0}\qquad\text{and}\qquad\mu_D=0 \tag{9.7.442}$$

and the equation:

$$\rho\mathrm{d}_t\vec{v}=-\vec{\nabla}p+\frac{4}{3}(\mu_d+\mu'_d)\vec{\nabla}(\vec{\nabla}\circ\vec{v})-\mu_d\vec{\nabla}\times(\vec{\nabla}\times\vec{v})+\rho\vec{f} \tag{9.7.443}$$

becomes simply:

$$\boxed{\vec{\nabla}p-\rho\vec{f}=\vec{0}} \tag{9.7.444}$$

which is the "equation of the static fluid" or the "fundamental law of the hydrostatic". In discrete and more classical (rearranged) form, we fall back on the relation that must textbooks provides and that we have also proved earlier above using another approach (gradient theorem):

$$p_2-p_1=\rho g(h_2-h_1) \tag{9.7.445}$$

or by taking the initial height as being equal to zero:

$$p_2=p_1+\rho g h_2 \tag{9.7.446}$$

Remark

As the viscosities disappear, the static fluids are the same for viscous or non-viscous fluids.

9.7.2.4.4 Reynolds number

The "Reynolds number (Re)" is an important dimensionless quantity in fluid mechanics that is used to help predict flow patterns in different fluid flow situations. It is widely used in many applications ranging from liquid flow in a pipe to the passage of air over an aircraft wing. The Reynolds Number is valuable as a guide to the transition point from laminar to turbulent flow in a particular flow situation, and for the scaling of similar but different-sized flow situations, such as between an aircraft model in a wind tunnel and the full size version.

Let us consider first, for simplicity, the incompressible case.

The equation of continuity, or conservation of mass, (see section Thermodynamics page 3683) that is for recall:

$$\rho\frac{\partial\rho}{\partial t}-\vec{\nabla}\circ(\rho\vec{v}_a)=0 \tag{9.7.447}$$

is then written in this particular case:

$$\rho\vec{\nabla}\circ\vec{v}_a=0\Rightarrow\vec{\nabla}\circ\vec{v}_a=\frac{\partial v_x}{\partial_x}+\frac{\partial v_y}{\partial_y}+\frac{\partial v_z}{\partial_z}=0 \tag{9.7.448}$$

We now choose several quantities of dimensionless references denoted by an index r such that:

$$\begin{gathered}
x'=\frac{x}{L_r},y'=\frac{y}{L_r},z'=\frac{z}{L_r} \qquad\qquad \rho'=\frac{\rho}{\rho_r},t'=\frac{t}{t_r}\\
\text{and}\\
v'_x=\frac{v_x}{v_r},v'_y=\frac{v_y}{v_r},v'_z=\frac{v_z}{v_r} \qquad\qquad f'_i=\frac{f_i}{f_r},p'=\frac{p}{p_r},\mu'_d=\frac{\mu_d}{\mu_r}
\end{gathered} \tag{9.7.449}$$

By these definitions, we have for example:

$$\frac{\partial v_x}{\partial x}=\frac{\partial(v_r v'_x)}{\partial(L_r x')}=\frac{v_r}{L_r}\frac{\partial v'_x}{\partial x'} \tag{9.7.450}$$

Therefore the equation of the deformations per unit of time becomes:

$$\rho\vec{\nabla}\circ\vec{v}=\frac{v_r}{L_r}\left(\frac{\partial v'_x}{\partial x'}+\frac{\partial v'_y}{\partial y'}+\frac{\partial v'_z}{\partial z'}\right)=0 \tag{9.7.451}$$

But we also have:

$$\rho\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=\frac{\partial\vec{v}}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial\vec{v}}{\partial t} \tag{9.7.452}$$

Let us restrict ourselves to the study of only one component:

$$\rho\frac{\mathrm{d}v_x}{\mathrm{d}t}=\frac{\partial v_x}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial v_x}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial v_x}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial v_x}{\partial t} \tag{9.7.453}$$

By multiplying this last relation by the density ρ and by definition of the speed we get:

$$\rho\frac{\mathrm{d}v_x}{\mathrm{d}t}=\rho\left[\frac{\partial v_x}{\partial_x}\frac{\mathrm{d}x}{\mathrm{d}t}+\frac{\partial v_x}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t}+\frac{\partial v_x}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}+\frac{\partial v_x}{\partial t}\right]=\rho\left[\frac{\partial v_x}{\partial x}v_x+\frac{\partial v_x}{\partial y}v_y+\frac{\partial v_x}{\partial z}v_z+\frac{\partial v_x}{\partial t}\right] \tag{9.7.454}$$

Let us now take one of the possible formulations of the Navier-Stokes equation proved earlier above:

$$\rho\mathrm{d}_t v_x=-\partial_x p+\frac{1}{3}\mu_d\partial_x\partial_x(\vec{\nabla}\circ\vec{v})+\mu_d\vec{\nabla}\circ(\vec{\nabla}(v_x))+\rho f_x \tag{9.7.455}$$

By not forgetting that for an incompressible fluid we have:

$$\vec{\nabla}\circ\vec{v}=0 \tag{9.7.456}$$

the previous Navier-Stokes equation, reduces then to:

$$\rho\frac{\mathrm{d}v_x}{\mathrm{d}t}=-\frac{\partial p}{\partial x}+\mu_d\left(\frac{\partial}{\partial x}\frac{\partial}{\partial x}v_x+\frac{\partial}{\partial y}\frac{\partial}{\partial y}v_y+\frac{\partial}{\partial z}\frac{\partial}{\partial z}v_x\right)+\rho f_x \tag{9.7.457}$$

But, for a fluid we had assumed above that the shear tensions were given by:

$$\tau_{xy}=\mu_d\partial_x v_y \tag{9.7.458}$$

The terms where the viscosity coefficients appear can be rewritten such that:

$$\rho\frac{\mathrm{d}v_x}{\mathrm{d}t}=-\frac{\partial p}{\partial x}+\left(\frac{\partial\tau_{xx}}{\partial x}+\frac{\partial\tau_{yx}}{\partial y}+\frac{\partial\tau_{zx}}{\partial z}\right)+\rho f_x \tag{9.7.459}$$

Thus by correspondence:

$$\rho\left[\frac{\partial v_x}{\partial x}v_x+\frac{\partial v_x}{\partial y}v_y+\frac{\partial v_x}{\partial z}v_z+\frac{\partial v_x}{\partial t}\right]=-\frac{\partial p}{\partial x}+\left(\frac{\partial\tau_{xx}}{\partial x}+\frac{\partial\tau_{yx}}{\partial y}+\frac{\partial\tau_{zx}}{\partial z}\right)+\rho f_x \tag{9.7.460}$$

that we can write in even more condensed form by using a rather abusive tensor notation:

$$\rho\frac{\mathrm{d}v_x}{\mathrm{d}t}=-\frac{\partial p}{\partial x}+\frac{\partial\tau_{ij}}{\partial x_i}+\rho f_x \tag{9.7.461}$$

By introducing the dimensionless variables:

$$\rho'\rho_r\left[\frac{v_r^2}{L_r}\left(\frac{\partial v'_x}{\partial x'}v'_x+\frac{\partial v'_y}{\partial y'}v'_y+\frac{\partial v'_z}{\partial z'}v'_z\right)+\frac{v_r}{t_r}\frac{\partial v'_x}{\partial t'}\right]=-\frac{p_r}{L_r}\frac{\partial p'}{\partial x'}+\frac{v_r\mu_r}{L_r}\frac{1}{L_r}\frac{\tau'_{ij}}{\partial x'_i}+\rho_r\rho' f_r f'_x \tag{9.7.462}$$

Let us now multiply this last relation by $\dfrac{L_r}{v^2}$ and let us divide it by ρ_r on both sides of equality such that it becomes:

$$\rho'\left[\left(\frac{\partial v'_x}{\partial x'}v'_x+\frac{\partial v'_y}{\partial y'}v'_y+\frac{\partial v'_z}{\partial z'}v'_z\right)+\frac{L_r}{t_r v_r}\frac{\partial v'_x}{\partial t'}\right]=-\frac{p_r}{\rho_r v_r^2}\frac{\partial p'}{\partial x'}+\frac{\mu_r}{\rho_r L_r v_r}\frac{1}{L_r}\frac{\tau'_{ij}}{\partial x'_i}+\rho'\frac{L_r}{v_r^2}f_r f'_x \tag{9.7.463}$$

At the dimensional level, let us notice that we have:

$$t_r=\frac{L_r}{v_r}\qquad \frac{p_r}{\rho_r v_r^2}=1\qquad \frac{L_r}{v_r^2}f_r=1 \tag{9.7.464}$$

Finally:

$$\boxed{\rho'\left[\left(\frac{\partial v'_x}{\partial x'}v'_x+\frac{\partial v'_y}{\partial y'}v'_y+\frac{\partial v'_z}{\partial z'}v'_z\right)+\frac{\partial v'_x}{\partial t'}\right]=-\frac{\partial p'}{\partial x'}+\frac{1}{\text{Re}}\frac{\tau'_{ij}}{\partial x'_i}+\rho' f'_x} \tag{9.7.465}$$

This differential equation expressed in relative and dimensionless variables is named the "dimensionless Navier-Stokes-Reynolds equation".

The term Re, as we know is the Reynolds number, symbolically represented the ratio of the inertial forces to the viscous forces:

$$\boxed{\text{Re}=\frac{\rho_r L_r v_r}{\mu_r}=\frac{L_r v_r}{\mu_{rc}}} \tag{9.7.466}$$

where μ_{rc} is the "relative kinematic viscosity". The dynamic viscosity is therefore a term inversely proportional to the value of the Reynolds number.

We also often find this last relation in the following form (term-to-term identification with the first equation of the previous expression where $2R$ is the diameter of the circular section of the tube that transports the fluid):

$$N_{\text{Re}}=\frac{\rho 2R\bar{u}}{\mu} \tag{9.7.467}$$

If instead of the velocity it is the mass flow which is measured through a circular section, we then have using the following relation between the mass flow rate and fluid velocity in a cylindrical tube:

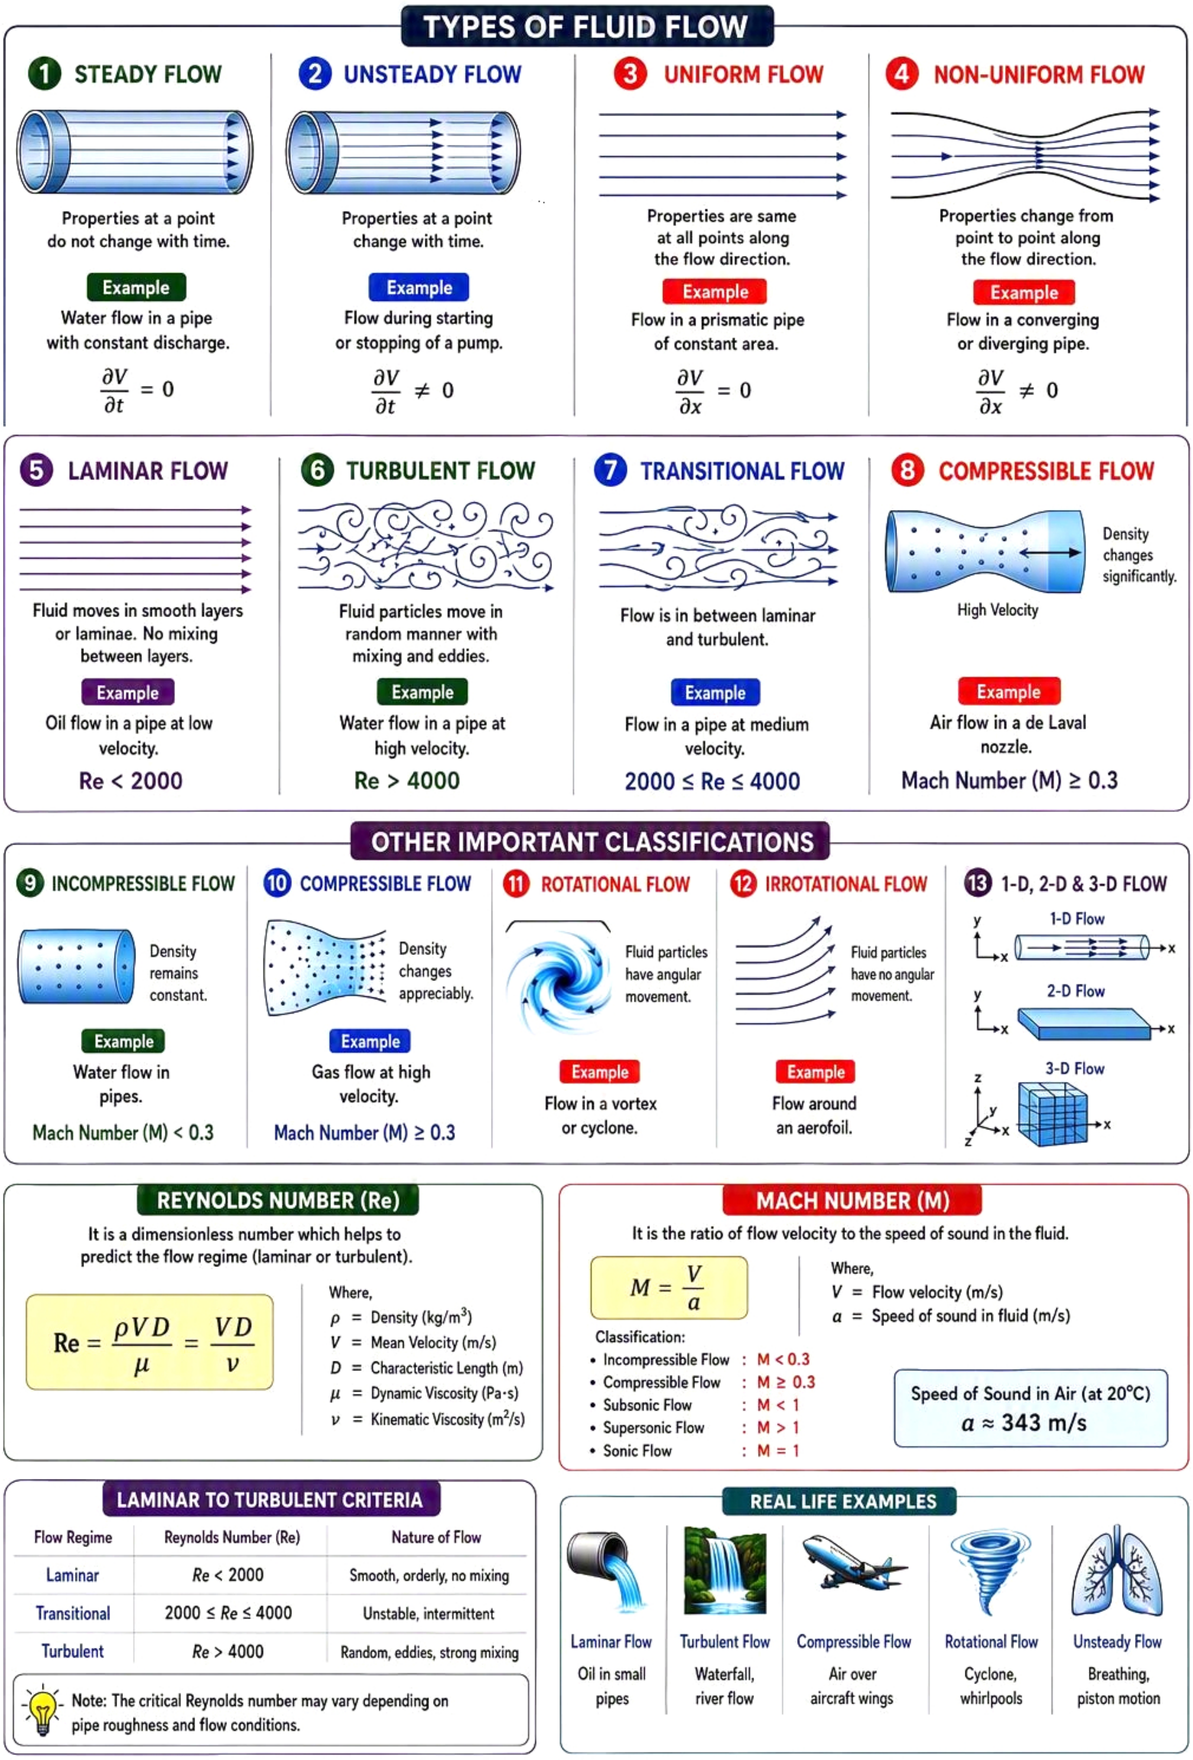
$$J=\frac{\Delta V}{\Delta t}=\frac{S\Delta d}{\Delta t}=Sv=\pi R^2 v\Rightarrow \dot{m}=J\rho=\pi R^2 v\rho\Rightarrow v=\frac{\dot{m}}{\pi R^2\rho} \tag{9.7.468}$$

Another writing for the prior-previous relation that we will often using in industrial practice:

$$N_{\text{Re}}=\frac{\rho 2R\left(\dfrac{\dot{m}}{\pi R^2\rho}\right)}{\mu}=\frac{2\dot{m}}{\mu\pi R}=\frac{2\dot{m}}{\mu\pi\dfrac{\varnothing}{2}}=\frac{4\dot{m}}{\mu\pi\varnothing} \tag{9.7.469}$$

In practice we regularly calculate the time it would take to fill a given volume tank with a fluid having a known mass flow rate, a known density, a known viscosity and a known number of Reynolds in a cylindrical pipe whose radii are also known. Therefore it comes:

$$t=\frac{V}{J}=\frac{V}{\dfrac{\Delta V}{\Delta t}}=\frac{V}{Sv}=\frac{V}{S\dfrac{\dot{m}}{\pi R^2\rho}}=\frac{V\rho}{\dot{m}}=\frac{4V\rho}{N_{\text{Re}}\mu\pi\varnothing} \tag{9.7.470}$$



TYPES OF FLUID FLOW

① STEADY FLOW

Properties at a point do not change with time.

Example

Water flow in a pipe with constant discharge.

$$\frac{\partial V}{\partial t} = 0$$

② UNSTEADY FLOW

Properties at a point change with time.

Example

Flow during starting or stopping of a pump.

$$\frac{\partial V}{\partial t} \neq 0$$

③ UNIFORM FLOW

Properties are same at all points along the flow direction.

Example

Flow in a prismatic pipe of constant area.

$$\frac{\partial V}{\partial x} = 0$$

④ NON-UNIFORM FLOW

Properties change from point to point along the flow direction.

Example

Flow in a converging or diverging pipe.

$$\frac{\partial V}{\partial x} \neq 0$$

⑤ LAMINAR FLOW

Fluid moves in smooth layers or laminae. No mixing between layers.

Example

Oil flow in a pipe at low velocity.

Re < 2000

⑥ TURBULENT FLOW

Fluid particles move in random manner with mixing and eddies.

Example

Water flow in a pipe at high velocity.

Re > 4000

⑦ TRANSITIONAL FLOW

Flow is in between laminar and turbulent.

Example

Flow in a pipe at medium velocity.

2000 ≤ Re ≤ 4000

⑧ COMPRESSIBLE FLOW

Density changes significantly.

Example

Air flow in a de Laval nozzle.

Mach Number (M) ≥ 0.3

OTHER IMPORTANT CLASSIFICATIONS

⑨ INCOMPRESSIBLE FLOW

Density remains constant.

Example

Water flow in pipes.

Mach Number (M) < 0.3

⑩ COMPRESSIBLE FLOW

Density changes appreciably.

Example

Gas flow at high velocity.

Mach Number (M) ≥ 0.3

⑪ ROTATIONAL FLOW

Fluid particles have angular movement.

Example

Flow in a vortex or cyclone.

⑫ IRROTATIONAL FLOW

Fluid particles have no angular movement.

Example

Flow around an aerofoil.

⑬ 1-D, 2-D & 3-D FLOW

REYNOLDS NUMBER (Re)

It is a dimensionless number which helps to predict the flow regime (laminar or turbulent).

$$\mathrm{Re} = \frac{\rho V D}{\mu} = \frac{V D}{\nu}$$

Where,

ρ = Density (kg/m^3)

V = Mean Velocity (m/s)

D = Characteristic Length (m)

μ = Dynamic Viscosity (Pa·s)

ν = Kinematic Viscosity (m^2/s)

MACH NUMBER (M)

It is the ratio of flow velocity to the speed of sound in the fluid.

$$M = \frac{V}{a}$$

Where,

V = Flow velocity (m/s)

a = Speed of sound in fluid (m/s)

Classification:

- Incompressible Flow : M < 0.3
- Compressible Flow : M ≥ 0.3
- Subsonic Flow : M < 1
- Supersonic Flow : M > 1
- Sonic Flow : M = 1

Speed of Sound in Air (at 20°C)

$a \approx 343$ m/s

LAMINAR TO TURBULENT CRITERIA

Flow Regime	Reynolds Number (Re)	Nature of Flow
Laminar	$Re < 2000$	Smooth, orderly, no mixing
Transitional	$2000 \le Re \le 4000$	Unstable, intermittent
Turbulent	$Re > 4000$	Random, eddies, strong mixing

Note: The critical Reynolds number may vary depending on pipe roughness and flow conditions.

REAL LIFE EXAMPLES

Laminar Flow	Turbulent Flow	Compressible Flow	Rotational Flow	Unsteady Flow
Oil in small pipes	Waterfall, river flow	Air over aircraft wings	Cyclone, whirlpools	Breathing, piston motion

9.7.2.4.5 Boussinesq approximation (buoyancy)

In fluid dynamics, the Boussinesq approximation is used in the field of buoyancy-driven flow (also known as natural convection). It ignores density differences except where they appear in terms multiplied by g, the acceleration due to gravity. The essence of the Boussinesq approximation is that the difference in inertia is negligible but gravity is sufficiently strong to make the specific weight appreciably different between the two fluids. Sound waves are impossible/neglected when the Boussinesq approximation is used since sound waves move via density variations.

Boussinesq flows are common in nature (such as atmospheric fronts, oceanic circulation, katabatic winds), industry (dense gas dispersion, fume cupboard ventilation), and the built environment (natural ventilation, central heating). The approximation is extremely accurate for many such flows, and makes the mathematics and physics simpler.

Given the relation already proved previously:

$$\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+2\vec{\omega}\times\vec{v}=\vec{0} \tag{9.7.471}$$

Putting in it again the term containing the viscosity:

$$\partial_t\vec{v}+\vec{\nabla}\left[\frac{v^2}{2}+\frac{p}{\rho}+U\right]+2\vec{\omega}\times\vec{v}-\mu_d\vec{\nabla}^2 v=\vec{0} \tag{9.7.472}$$

without forgetting that at the notation level (we know ... it's a bit annoying):

$$\Delta\cdot v=\vec{\nabla}^2 v=\vec{\nabla}\circ(\vec{\nabla}\cdot\vec{v})=\vec{\nabla}(\vec{\nabla}\circ\vec{v})-\vec{\nabla}\times(\vec{\nabla}\times\vec{v}) \tag{9.7.473}$$

If the potential is a gravitational one, it goes without saying that:

$$\vec{\nabla}\cdot U=\vec{\nabla}\cdot(gz)=\vec{g} \tag{9.7.474}$$

Therefore:

$$\partial_t\vec{v}+\vec{\nabla}\frac{v^2}{2}+\frac{1}{\rho}\vec{\nabla}p+\vec{g}+2\vec{\omega}\times\vec{v}-\mu_d\vec{\nabla}^2 v=\vec{0} \tag{9.7.475}$$

$$\partial_t\vec{v}+\vec{\nabla}\frac{v^2}{2}+\frac{1}{\rho}\vec{\nabla}p+\vec{g}+2\vec{\omega}\times\vec{v}-\mu_d\vec{\nabla}v=\vec{0} \tag{9.7.476}$$

If we can consider the context of the experiment such that the volume density is less than or equal to that of the water and the velocities are small, then we can eliminate the second degree terms such that the previous relation will be written:

$$\partial_t\vec{v}+2\vec{\omega}\times\vec{v}+\frac{1}{\rho}\vec{\nabla}p+\vec{g}-\mu_d\vec{\nabla}^2 v=\vec{0} \tag{9.7.477}$$

We place ourselves within the framework of a weakly turbulent fluid, in which the pressure and the density are written:

$$p=p_0+p' \qquad \rho=\rho_0+\rho' \qquad \frac{\rho'}{\rho_0}\ll 1 \tag{9.7.478}$$

where p', ρ' represents the turbulent increasing terms with respect to the static values of the fluid.

We also neglect the friction on the bounds and therefore the viscosity, assuming that the effect of the turbulence quickly becomes preponderant on the value of the friction.

So we have the system of equations:

$$\partial_t\vec{v}+2\vec{\omega}\times\vec{v}+\frac{1}{\rho}\vec{\nabla}p+\vec{g}=\vec{0} \tag{9.7.479}$$

that can be written:

$$\rho\partial_t\vec{v}+\rho 2\vec{\omega}\times\vec{v}+\vec{\nabla}p+\rho\vec{g}=\vec{0} \tag{9.7.480}$$

and even:

$$\rho\partial_t\vec{v}+\rho 2\vec{\omega}\times\vec{v}+\vec{\nabla}(p_0+p')+(\rho_0+\rho')\vec{g}=\vec{0} \tag{9.7.481}$$

which can also written:

$$\rho\partial_t\vec{v}+\rho 2\vec{\omega}\times\vec{v}+(\vec{\nabla}p'+\rho'\vec{g})+(\vec{\nabla}p_0+\rho_0\vec{g})=\vec{0} \tag{9.7.482}$$

But in the static case we know (we proved it many times) that we have:

$$\vec{\nabla}p_0+\rho\vec{g}=\vec{0} \tag{9.7.483}$$

It then remains to us:

$$\rho\partial_t\vec{v}+\rho 2\vec{\omega}\times\vec{v}+\vec{\nabla}p'+\rho'\vec{g}=\vec{0} \tag{9.7.484}$$

Therefore it remains:

$$\rho\partial_t\vec{v}+\rho 2\vec{\omega}\times\vec{v}+\vec{\nabla}p'+\rho'\vec{g}=\vec{0} \tag{9.7.485}$$

By dividing the whole by ρ:

$$\partial_t\vec{v}+2\vec{\omega}\times\vec{v}+\frac{1}{\rho}\vec{\nabla}p'+\frac{\rho'}{\rho}\vec{g}=\vec{0} \tag{9.7.486}$$

but again we can write this:

$$\partial_t\vec{v}+2\vec{\omega}\times\vec{v}+\frac{1}{\rho'+\rho_0}\vec{\nabla}p'+\frac{\rho'}{\rho+\rho_0}\vec{g}=\vec{0} \tag{9.7.487}$$

The Boussinesq approximation consisting of supposing that the fluid is incompressible and that the system is at constant temperature and not very turbulent, we have:

$$\rho_0\gg\rho' \tag{9.7.488}$$

Which gives us:

$$\boxed{\partial_t\vec{v}+2\vec{\omega}\times\vec{v}+\frac{1}{\rho_0}\vec{\nabla}p'+\frac{\rho'}{\rho_0}\vec{g}=\vec{0}} \tag{9.7.489}$$

This equation is named the "Boussinesq equation" and will allow us to introduce the theory of chaos in the field of meteorology and fluids in the particular case of convection cells (see section Weather & Marine Engineering page 8328).

9.7.2.4.6 Stokes' law

In 11851 (holocene calendar), George Gabriel Stokes derived an expression, now known as Stokes' law, for the frictional force - also named drag force - exerted on spherical objects with very small Reynolds numbers (i.e. very small particles) in a viscous fluid. Stokes' law is derived by solving the Stokes flow limit for small Reynolds numbers of the Navier–Stokes equations.

The complexity of hydrodynamics is a suitable framework for the application of dimensional analysis which we introduced at the very beginning of our study of Mechanics (see section Principia page 3080). The example analyzed here clearly shows the possibilities, but also the limitations of this method.

We consider a solid of any form immersed in an incompressible fluid with a uniform velocity at great distance (the problem is equivalent to that of a solid which moves at a constant velocity in a fluid at rest). We try to express the force F that the fluid exerts on the obstacle, supposed to be immobile (and in particular devoid of any rotational motion).

The analytical solution is too complex to waste time solving this kind of practical problem. Dimensional analysis should be used.

The relevant parameters are in our study:

- L the linear dimension of the obstacle
- v the fluid velocity at far distances
- ρ the fluid density
- μ the viscosity coefficient of the fluid

As a matter of fact, all these parameters are constants, even if the velocity varies in direction and norm in the vicinity of the obstacle: at long distances, it is uniform and its value v is indeed a relevant parameter.

We might ask ourselves if pressure should not be one of those parameters. This is not the case. The pressure is conditioned by the value of the velocity and by those of the constant parameters as we saw in Bernoulli's theorem. There is no need to add a redundant term.

Without seeking the unique combination without dimension of the first four, we apply the systematic approach. We want to determine A, B, C, D such that:

$$F = L^A v^B \rho^C \mu^D \tag{9.7.490}$$

As:

$$F:[\mathrm{kg}\cdot\mathrm{m}\cdot\mathrm{s}^{-2}] \qquad \rho:[\mathrm{kg}\cdot\mathrm{m}^{-3}] \qquad v:[\mathrm{m}\cdot\mathrm{s}^{-1}] \qquad \mu:[\mathrm{kg}\cdot\mathrm{m}^{-1}\cdot\mathrm{s}^{-1}] \tag{9.7.491}$$

It comes:

$$\mathrm{kg}\cdot\mathrm{m}\cdot\mathrm{s}^{-2} = \mathrm{kg}^{C+D}\cdot\mathrm{m}^{A+B-3C-D}\cdot\mathrm{s}^{-B-D} \tag{9.7.492}$$

The dimensionality system is then written:

$$\begin{aligned}&C+D=1\rightarrow C=1-D\\&A+B-3C-D=1\\&B+D=2\Rightarrow B=2-D\end{aligned}\tag{9.7.493}$$

Therefore:

$$A=1-B+3C+D=2-D\tag{9.7.494}$$

Hence:

$$F=\rho v^2L^2\left(\frac{Lv\rho}{\mu}\right)^{-D}\tag{9.7.495}$$

and curiously we fall back here in the parenthesis on what we had seen in our development of the Reynolds number:

$$\text{Re}=\frac{\rho_r L_r v_r}{\mu_{rd}}=\frac{L_r v_r}{\mu_{rc}}\tag{9.7.496}$$

Thus the force exerted by the fluid is then written:

$$F=\rho v^2L^2\text{Re}^{-D}\tag{9.7.497}$$

In the literature, we find the notation for the drag force:

$$\boxed{F=\rho v^2L^2C(\text{Re})}\tag{9.7.498}$$

Where C depends obviously on Re. We also find this relation in some textbooks in the following form:

$$F_D=\frac{1}{2}\rho V^2C_DA\tag{9.7.499}$$

Or in even more condensed form:

$$F_D=C_Dv^2\tag{9.7.500}$$

where appears the "drag coefficient C_D" which is determined in wind tunnels or experimentally based on the fact that an object in free fall in a perfect liquid or gas will follow the differential equation:

$$m\frac{\mathrm{d}v}{\mathrm{d}t}=mg-C_Dv^2\tag{9.7.501}$$

Differential equation that we can solve ingeniously by writing:

$$m\frac{\mathrm{d}x}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}t}=mv\frac{\mathrm{d}v}{\mathrm{d}x}=mg-C_Dv^2\tag{9.7.502}$$

It then comes after rearrangement of the terms:

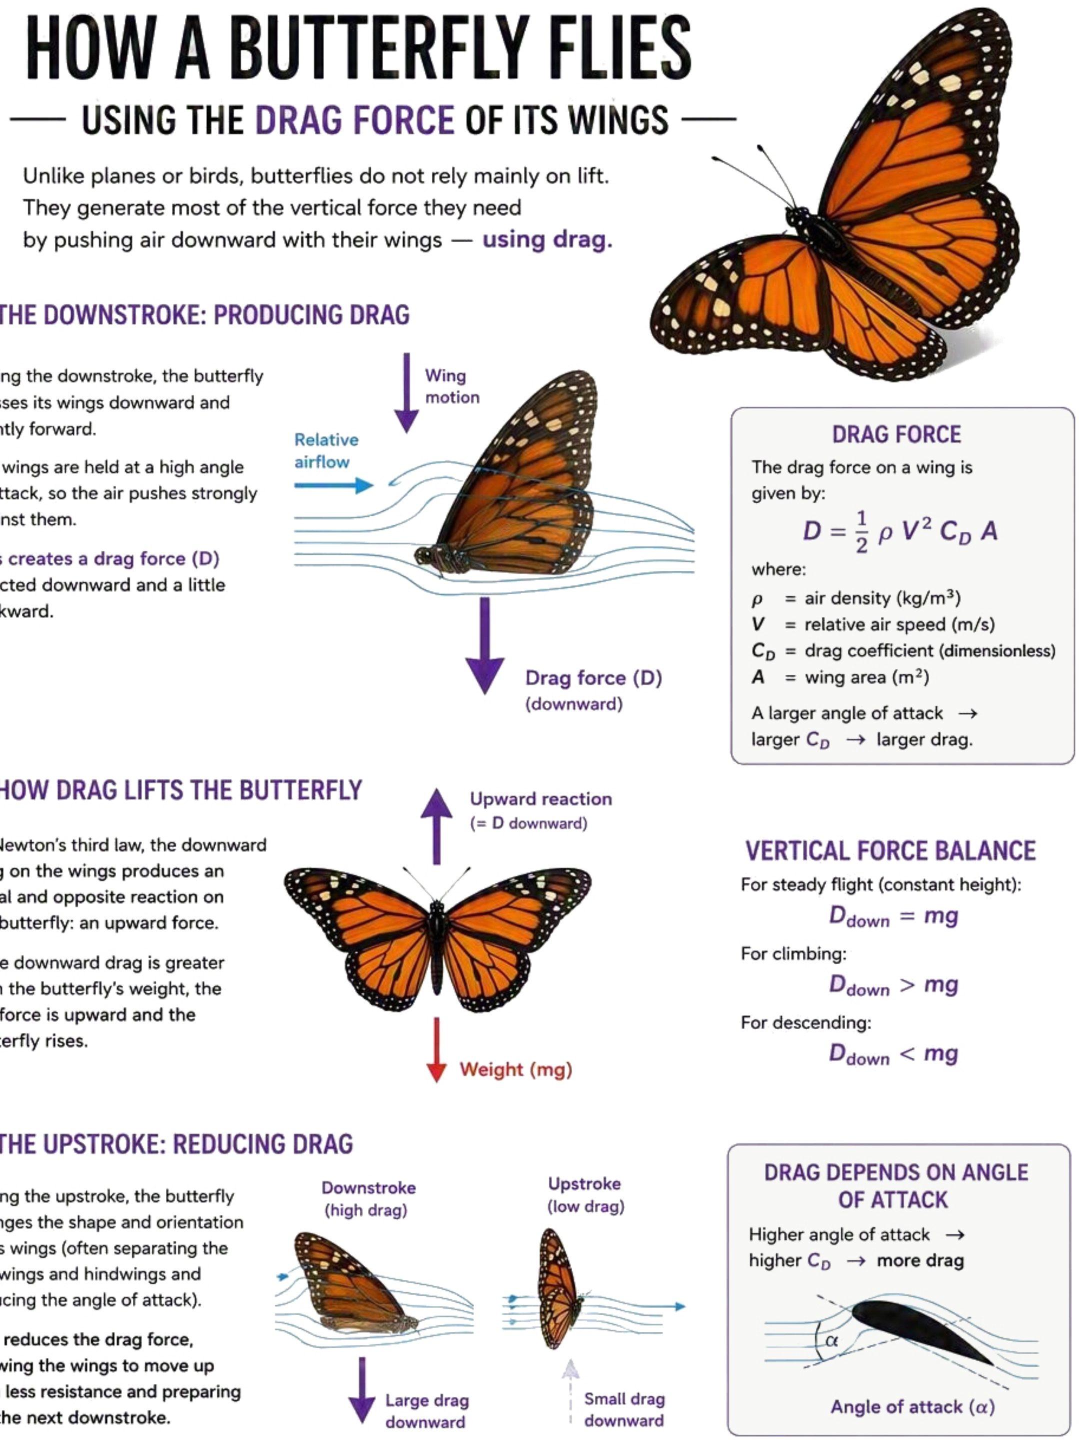
$$\frac{v\mathrm{d}v}{1-\dfrac{C_D}{mg}v^2}=g\mathrm{d}x\tag{9.7.503}$$

Either after integration:

$$\ln\left(1-\frac{C_D}{mg}v^2\right)=-2\frac{C_D}{m}x \tag{9.7.504}$$

Then it comes a relation which makes it possible to determine experimentally the drag coefficient for an object in free fall without too many difficulties:

$$v^2=\frac{mg}{C_D}\left(1+e^{-2\frac{C_D}{m}x}\right) \tag{9.7.505}$$



HOW A BUTTERFLY FLIES

— USING THE DRAG FORCE OF ITS WINGS —

Unlike planes or birds, butterflies do not rely mainly on lift. They generate most of the vertical force they need by pushing air downward with their wings — **using drag.**

1 THE DOWNSTROKE: PRODUCING DRAG

During the downstroke, the butterfly presses its wings downward and slightly forward.

The wings are held at a high angle of attack, so the air pushes strongly against them.

This creates a drag force (D) directed downward and a little backward.

DRAG FORCE

The drag force on a wing is given by:

$$D=\frac{1}{2}\rho V^2 C_D A$$

where:

ρ = air density (kg/m³)
V = relative air speed (m/s)
C_D = drag coefficient (dimensionless)
A = wing area (m²)

A larger angle of attack → larger C_D → larger drag.

2 HOW DRAG LIFTS THE BUTTERFLY

By Newton's third law, the downward drag on the wings produces an equal and opposite reaction on the butterfly: an upward force.

If the downward drag is greater than the butterfly's weight, the net force is upward and the butterfly rises.

VERTICAL FORCE BALANCE

For steady flight (constant height):

$$D_{\text{down}}=mg$$

For climbing:

$$D_{\text{down}}>mg$$

For descending:

$$D_{\text{down}}<mg$$

3 THE UPSTROKE: REDUCING DRAG

During the upstroke, the butterfly changes the shape and orientation of its wings (often separating the forewings and hindwings and reducing the angle of attack).

This reduces the drag force, allowing the wings to move up with less resistance and preparing for the next downstroke.

DRAG DEPENDS ON ANGLE OF ATTACK

Higher angle of attack → higher C_D → more drag

So if we want to check for a butterfly like the Gliding Swallowtail Butterfly that (we replace the drag coefficient C_D by the lift coefficient C_L):

$$\frac{1}{2}\rho V^2 C_L A \overset{?}{>} mg \tag{9.7.506}$$

we just have to replace the experimental numerical values taken from [431] (lift coeficient measured by fixing a real gliding swallowtail butterfly in a small wind tunnel), [598] and [98] to get:

$$\frac{1}{2}\cdot 1.225\cdot 1.4^2\cdot 0.65\cdot(7.011\cdot 10^{-3})\overset{?}{>}(4\cdot 10^{-5})\cdot 9.81 \tag{9.7.507}$$

That indeed satisfies observed reality (i.e. the Gliding Swallowtail Butterfly can fly...):

$$0.005471 > 0.000392 \tag{9.7.508}$$

So the lift force of this butterfly if approximately 13 times greater than the force of gravity!

Remark

Obviously C_D contains a mass unit, so nothing prevents us to extract a mass term and also a factor $1/2$, and also the surface of the object S (obviously we can guess that the surface has an incidence on the drag force..) to introduce a new drag coefficient denoted C such that we define the "drag force" as:

$$F_D = \frac{1}{2}Cmv^2 = \frac{1}{2}C\rho S v^2 \tag{9.7.509}$$

Then the "terminal velocity" (equilibrium between the gravitational force and drag force of a falling object in gas or liquid) is simply given by:

$$mg = F_D \Leftrightarrow mg = \frac{1}{2}C\rho S v^2 \tag{9.7.510}$$

Hence:

$$\boxed{v = \sqrt{\frac{2mg}{\rho C S}}} \tag{9.7.511}$$

✍**Example:**

To keep an object in motion in the presence of drag (aerodynamic or otherwise) requires an ongoing input of energy. Work must be done over some time. Power must be used. Recall the following chain of reasoning that starts from the definition of power as the rate at which work is done:

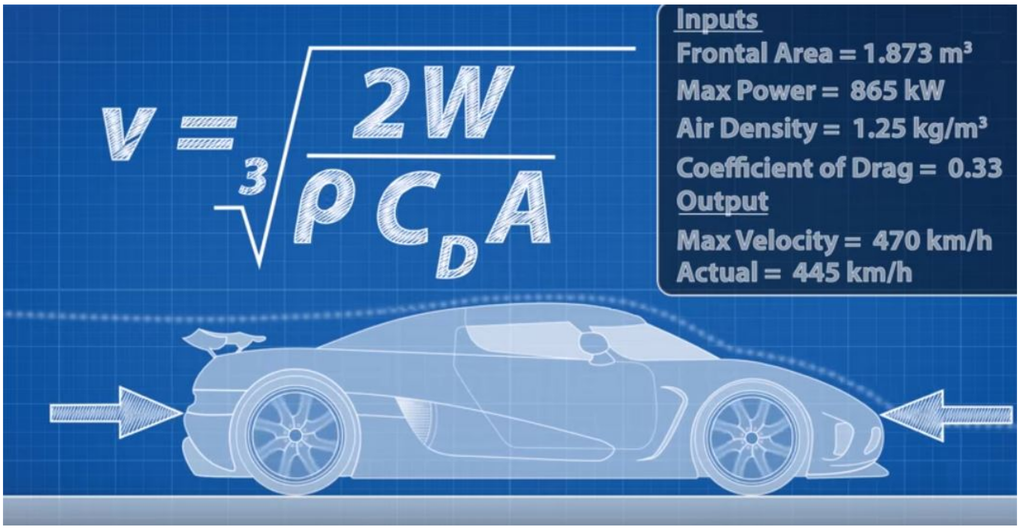
$$P = \frac{W}{t} = \frac{F\cdot x}{t} = F\cdot v \tag{9.7.512}$$

or more specifically, in the case of pressure drag:

$$P = F_D\cdot v = \left(\frac{1}{2}C\rho S v^2\right)v = \frac{1}{2}C\rho S v^3 \tag{9.7.513}$$

Therefore we have for maximum speed:

$$v=\sqrt[3]{\frac{2P}{\rho CS}} \tag{9.7.514}$$



$V=\sqrt[3]{\frac{2W}{\rho C_D A}}$
Inputs
Frontal Area = 1.873 m³
Max Power = 865 kW
Air Density = 1.25 kg/m³
Coefficient of Drag = 0.33
Output
Max Velocity = 470 km/h
Actual = 445 km/h

Figure 9.249: **Koenigsegg Agera RS theoretical maximum speed (source: Real Engineering/YouTube)**

The limits of the dimensional analytical method (and just analytic one...) appear when we confront this model with the experiment (obviously we could make numerical models of the Navier-Stokes-Reynolds equation for the computer and thus the honor would be safe):

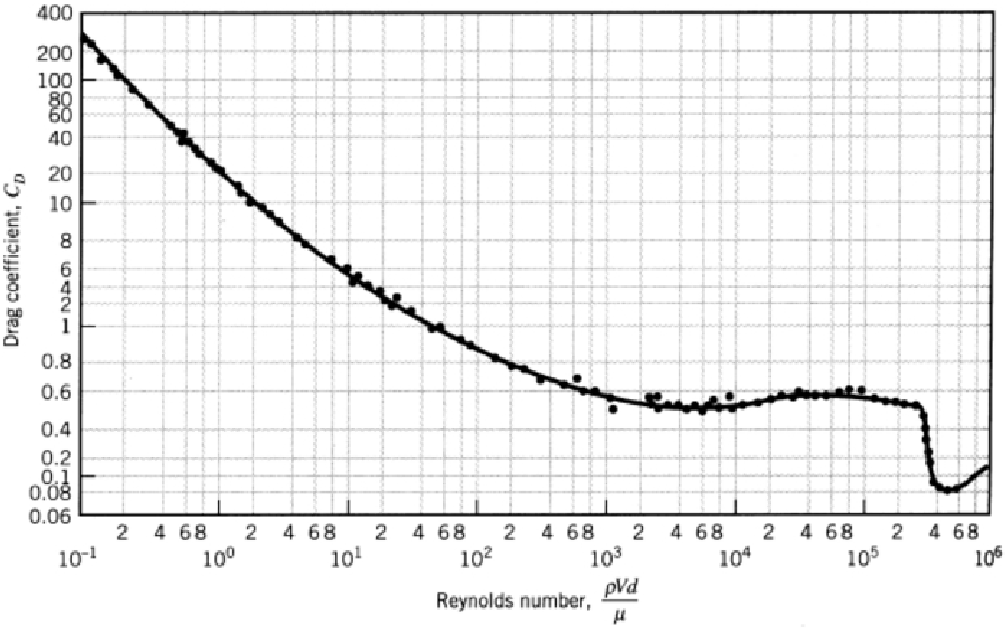


Figure 9.250: **Effect of Reynolds number on the drag coefficient C_D of a smooth sphere of diameter d**

or more explicitly:

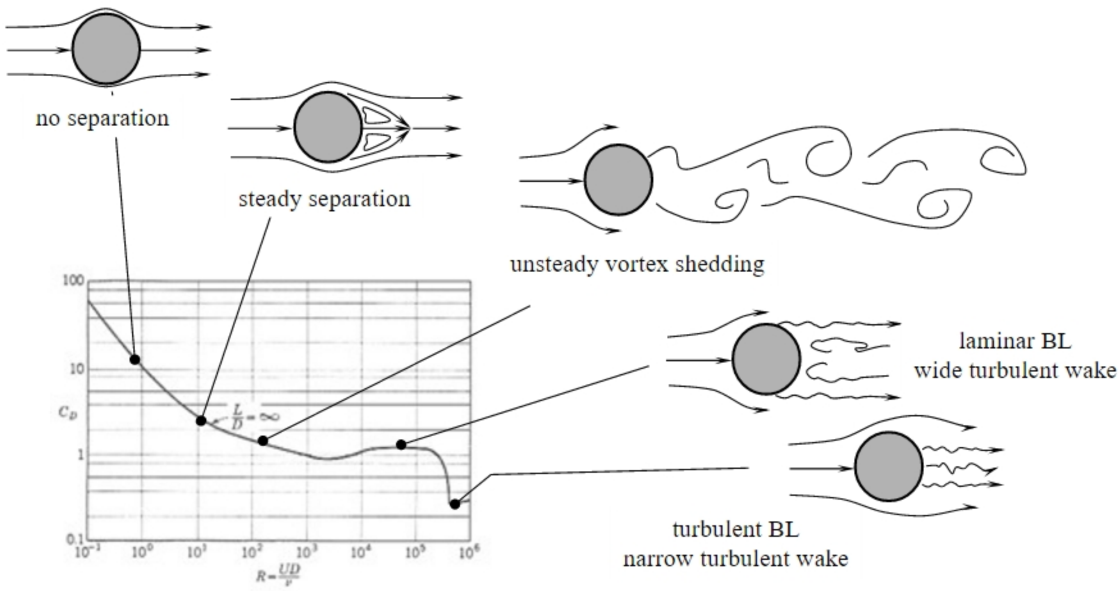

Figure 9.251: Effect of Reynolds number on the drag coefficient C_D of a smooth sphere with regime

Or comparing the drag coefficient of a sphere and a cylinder:

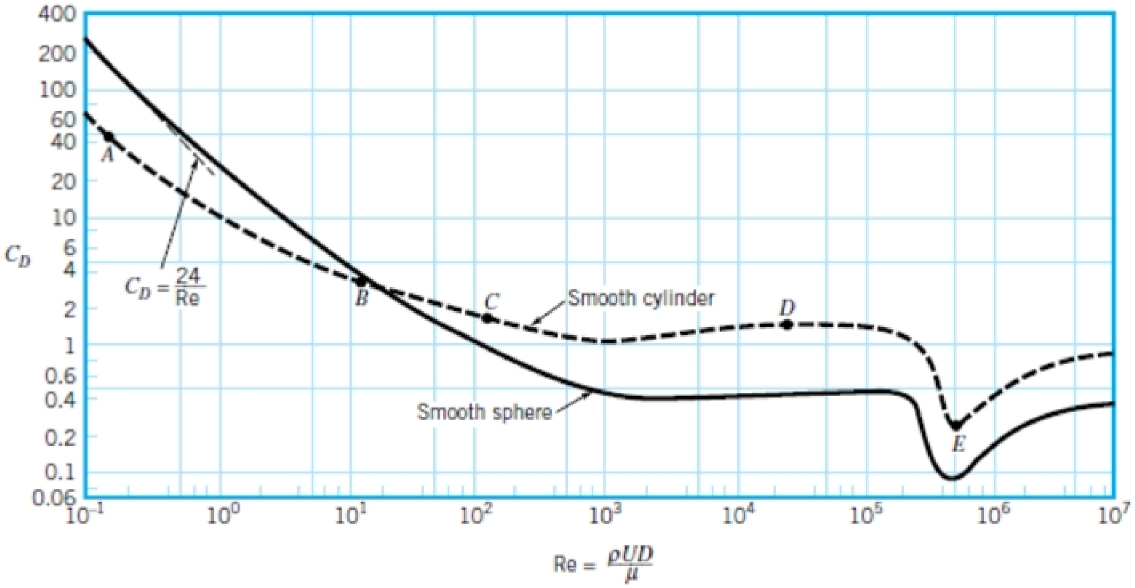

Figure 9.252: Drag coefficient comparison of a sphere and cylinder

The curves above have two remarkable characteristics:

1. It was obtained by independently modifying the values of the four parameters. We find that C_D depends only on the Reynolds number Re: it is a success of the dimensional analysis!
2. It seems useless to hope to find a simple analytic function which reproduces the experimental curve. We must therefore take a closer look at the various regimes corresponding to this complex curve.

The figure below schematizes the flow of a viscous fluid around a cylinder for different values of the Reynolds number:

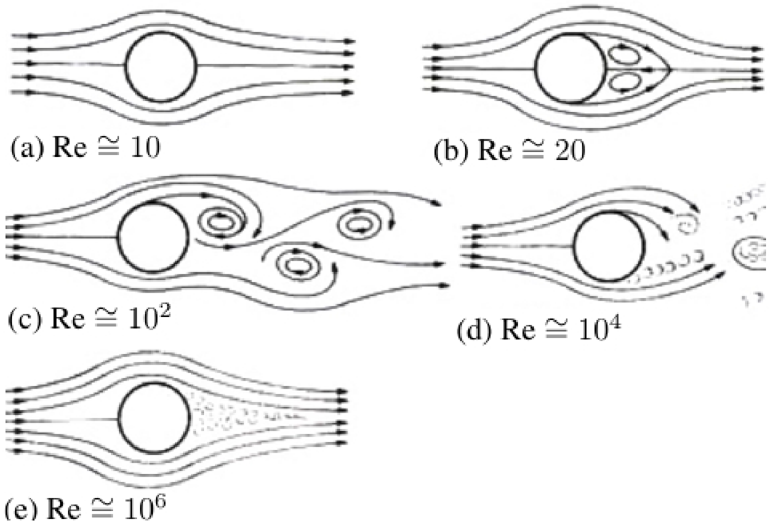

Figure 9.253: **Various fluid regimes for cylinder with corresponding Reynolds number**

The regime corresponding to figure (a) is name "steady state" or "steady regime". We can speak of a "quasi-static" movement on each point of the fluid where the acceleration is negligible. We must therefore expect that the inertia of the fluid does not intervene in the expression of force. For this, it is necessary and sufficient that:

$$\lim_{\text{Re}\to 0} C(\text{Re}) \to C'\frac{1}{\text{Re}} = C'\frac{\mu}{Lv\rho} \tag{9.7.515}$$

where C is independent of Re.

Therefore we have:

$$F = \rho v^2 L^2 C' \frac{\mu}{Lv\rho} = C'vL\mu \tag{9.7.516}$$

The parameter C' without dimensions can depend only on the geometry of the obstacle. In the case where the obstacle is spherical (very important case in physics with $L = R$), C' has been determined experimentally as being equall to 6π such that:

$$\boxed{F = 6\pi\mu R v} \tag{9.7.517}$$

known as the "Stokes' law" or "Stokes formula". Attention ... this law only applies well for small speeds and small spheres.

In the regime described by (b), two vortices takes place symmetrically behind the cylinder. When Re increases beyond 40, we distinguish the alley of "Kármán vortex street".

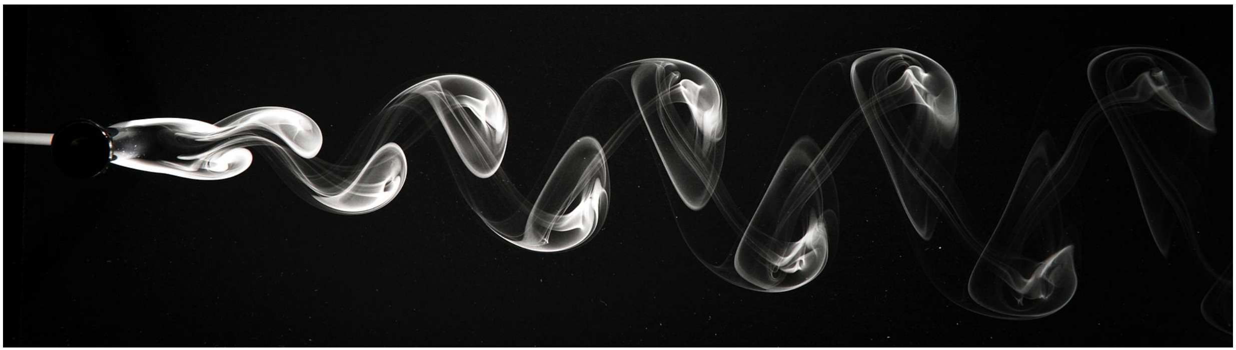

Figure 9.254: Visualisation of the vortex street behind a circular cylinder in air; the flow is made visible through release of oil vapour in the air near the cylinder (source: Wikipedia, author: Jürgen Wagner)

And at the macroscopic level on Earth typically (there is quantity of such photos on the Internet):

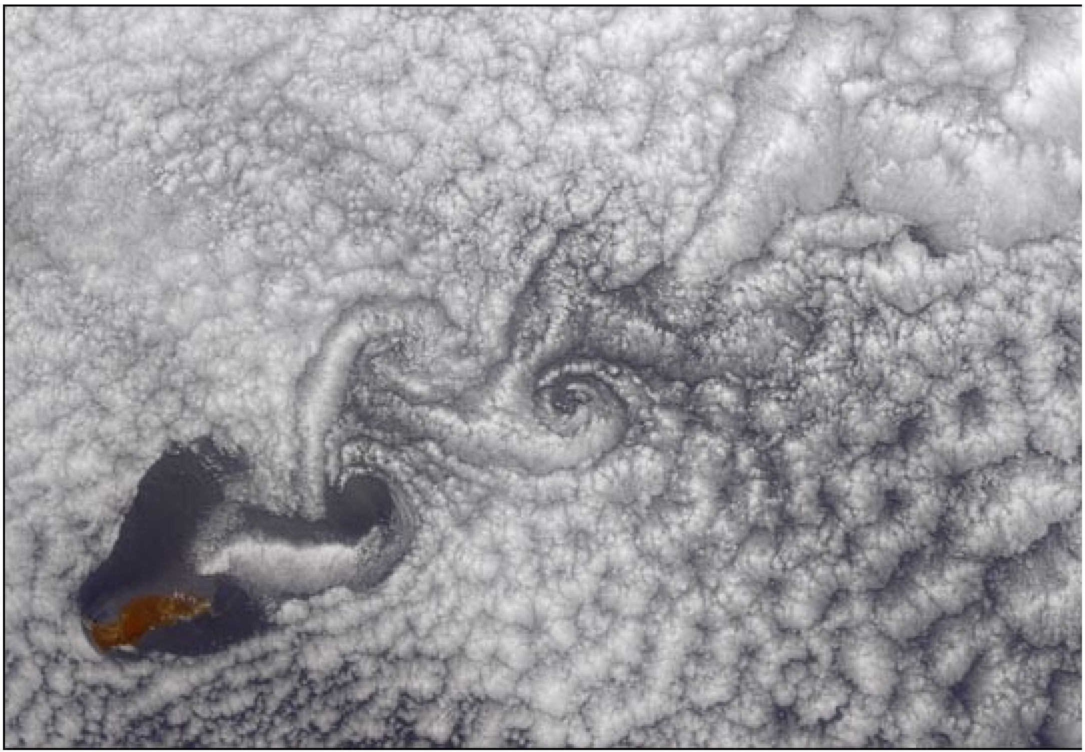

Figure 9.255: Visualization of the vortex street around Guadalupe island (source: NASA/GSFC/JPL, MISR Team)

And at a planetary level:

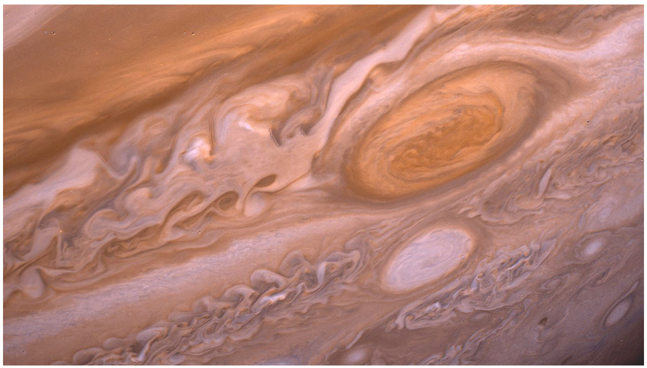

Figure 9.256: Visualisation of the vortex street around Jupiter red spot

9.7.2.4.6.1 Why don't clouds fall?

Clouds can hold an enormous amount of water. When this water falls as rain it clearly has a significant mass so why don't clouds fall? In fact, the small water droplets that make up clouds do fall slowly. However, the drag force of the air dominates over the gravitational force for small particles. The drag force increases as the size of an object decreases. The force needed to move a sphere through a viscous medium is given by Stokes's law:

$$F = 6\pi\mu R v \tag{9.7.518}$$

Here, R is the radius of the sphere, v is the velocity, and μ is the viscosity. The viscosity of air is about $0.018 \cdot 10^{-3}$ [Pa · s] and the viscosity of water is about $1.8 \cdot 10^{-3}$ [Pa · s]. Stokes's law is valid if the Reynolds number $N_{\text{Reynolds}} = 2R\rho v/\mu$ is less than about 2000. Here ρ is the mass density.

A spherical particle falling under the force of gravity will reach terminal velocity when the gravitational force matches the drag force:

$$mg = 6\pi\mu R v \tag{9.7.519}$$

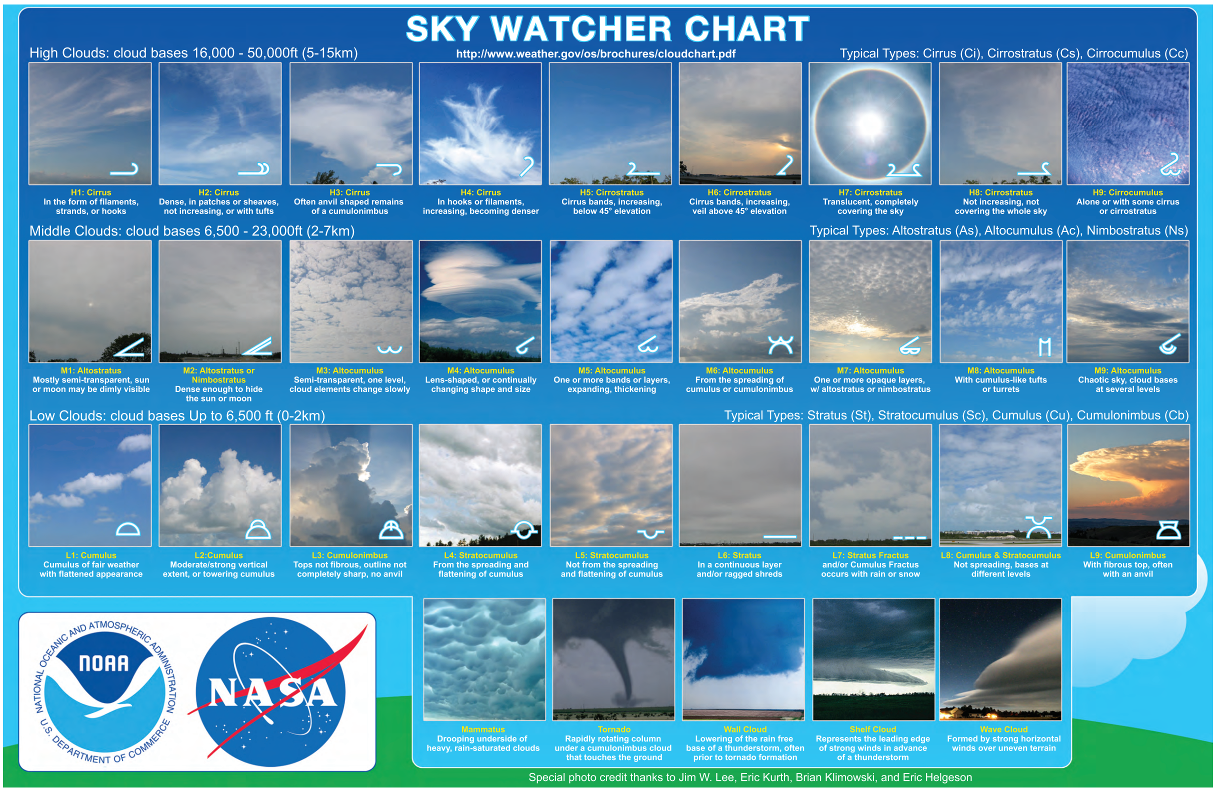
Solving this for the terminal velocity yields:

$$v_{\text{terminal}} = \frac{mg}{6\pi\mu v} = \frac{\left(\rho\frac{4}{3}\pi R^3\right) g}{6\pi\mu R} = \frac{2g\rho R^2}{9\eta} \tag{9.7.520}$$

A water droplet with a 10 [nm] radius falls at $12\,[\text{nm} \cdot \text{s}^{-1}]$ in air. It would take 2.6 years for this droplet to fall one meter. It is only when the small droplets begin to coalesce into larger droplets that they fall with significant speed.

In some sense, the inverse effect to rain is the rising of bubbles in beer. Bubbles are lighter than the surrounding liquid so gravity pushes them up. They rise with a constant velocity which is described by Stokes law. If you are the type that carefully observes your beer, you will have noticed that sometimes the bubbles move down. This is because of the circulation of liquid in the beer glass. The rising bubbles in the center of the glass drag some liquid along with them. After this liquid reaches the top of the glass, it returns to the bottom along the sides of the glass. This downward flow can drag bubbles, especially small bubbles, downwards against the force of gravity.

In a similar manner, small rain drops can be pull up by air currents against the force of gravity.



SKY WATCHER CHART
High Clouds: cloud bases 16,000 - 50,000ft (5-15km)
http://www.weather.gov/os/brochures/cloudchart.pdf
Typical Types: Cirrus (Ci), Cirrostratus (Cs), Cirrocumulus (Cc)
H1: Cirrus
In the form of filaments, strands, or hooks
H2: Cirrus
Dense, in patches or sheaves, not increasing, or with tufts
H3: Cirrus
Often anvil shaped remains of a cumulonimbus
H4: Cirrus
In hooks or filaments, increasing, becoming denser
H5: Cirrostratus
Cirrus bands, increasing, below 45° elevation
H6: Cirrostratus
Cirrus bands, increasing, veil above 45° elevation
H7: Cirrostratus
Translucent, completely covering the sky
H8: Cirrostratus
Not increasing, not covering the whole sky
H9: Cirrocumulus
Alone or with some cirrus or cirrostratus
Middle Clouds: cloud bases 6,500 - 23,000ft (2-7km)
Typical Types: Altostratus (As), Altocumulus (Ac), Nimbostratus (Ns)
M1: Altostratus
Mostly semi-transparent, sun or moon may be dimly visible
M2: Altostratus or Nimbostratus
Dense enough to hide the sun or moon
M3: Altocumulus
Semi-transparent, one level, cloud elements change slowly
M4: Altocumulus
Lens-shaped, or continually changing shape and size
M5: Altocumulus
One or more bands or layers, expanding, thickening
M6: Altocumulus
From the spreading of cumulus or cumulonimbus
M7: Altocumulus
One or more opaque layers, w/ altostratus or nimbostratus
M8: Altocumulus
With cumulus-like tufts or turrets
M9: Altocumulus
Chaotic sky, cloud bases at several levels
Low Clouds: cloud bases Up to 6,500 ft (0-2km)
Typical Types: Stratus (St), Stratocumulus (Sc), Cumulus (Cu), Cumulonimbus (Cb)
L1: Cumulus
Cumulus of fair weather with flattened appearance
L2:Cumulus
Moderate/strong vertical extent, or towering cumulus
L3: Cumulonimbus
Tops not fibrous, outline not completely sharp, no anvil
L4: Stratocumulus
From the spreading and flattening of cumulus
L5: Stratocumulus
Not from the spreading and flattening of cumulus
L6: Stratus
In a continuous layer and/or ragged shreds
L7: Stratus Fractus
and/or Cumulus Fractus occurs with rain or snow
L8: Cumulus & Stratocumulus
Not spreading, bases at different levels
L9: Cumulonimbus
With fibrous top, often with an anvil
NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION
NOAA
U.S. DEPARTMENT OF COMMERCE
NASA
Mammatus
Drooping underside of heavy, rain-saturated clouds
Tornado
Rapidly rotating column under a cumulonimbus cloud that touches the ground
Wall Cloud
Lowering of the rain free base of a thunderstorm, often prior to tornado formation
Shelf Cloud
Represents the leading edge of strong winds in advance of a thunderstorm
Wave Cloud
Formed by strong horizontal winds over uneven terrain

9.7.2.4.7 Betz's law

"Betz's law" indicates the maximum power that can be extracted from the wind, independent of the design of a wind turbine in open flow. It was published in 1919 by the German physicist Albert Betz[36]. The law is derived from the principles of conservation of mass and momentum of the air stream flowing through an idealized "actuator disk" that extracts energy from the wind stream. According to Betz's law, no turbine can capture more than $16/27$ (59.3%) of the kinetic energy in wind. The factor $16/27$ (0.593) is known as "Betz's coefficient". Practical utility-scale wind turbines achieve at peak 75 to 80% of the Betz limit.

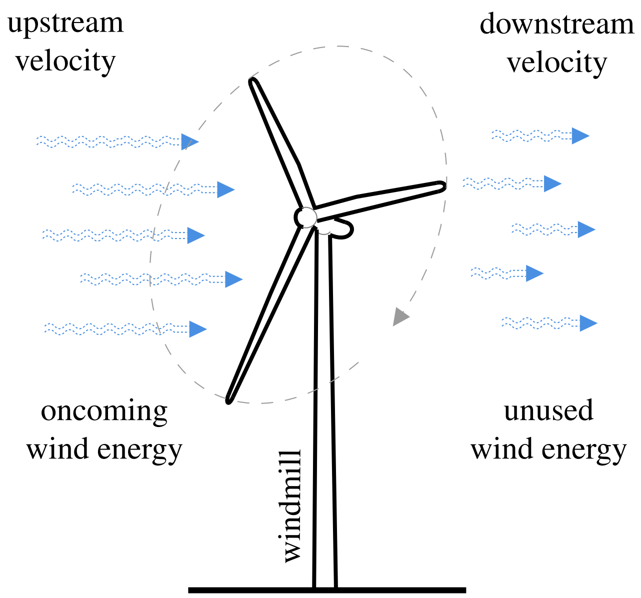
Betz's law applies to all Newtonian fluids, including wind. If all of the energy coming from wind movement through a turbine were extracted as useful energy, the wind speed afterwards would drop to zero. If the wind stopped moving at the exit of the turbine, then no more fresh wind could get in; it would be blocked. In order to keep the wind moving through the turbine, there has to be some wind movement, however small, on the other side with some wind speed greater than zero. Betz's law shows that as air flows through a certain area, and as wind speed slows from losing energy to extraction from a turbine, the airflow must distribute to a wider area. As a result, geometry limits any turbine efficiency to a maximum of 59.3%.

The Betz Limit is the maximum possible energy that may be derived by means of an infinitely thin rotor from a fluid flowing at a certain speed.

---

[36] British scientist Frederick W. Lanchester derived the same maximum in 1915. The leader of the Russian aerodynamic school, Nikolay Zhukowsky, also published the same result for an ideal wind turbine in 1920, the same year as Betz did. It is thus an example of Stigler's law, which posits that no scientific discovery is named after its actual discoverer.

In order to calculate the maximum theoretical efficiency of a thin rotor (of, for example, a windmill) one imagines it to be replaced by a disc that withdraws energy from the fluid passing through it. At a certain distance behind this disc the fluid that has passed through flows with a reduced velocity.



The assumptions are:

- The rotor does not possess a hub and is ideal, with an infinite number of blades, which have no drag. Any resulting drag would only lower this idealized value.
- The flow into and out of the rotor is axial. This is a control-volume analysis, and to construct a solution, the control volume must contain all flow going in and out, failure to account for that flow would violate the conservation equations.
- The flow is non-compressible. Density remains constant, and there is no heat transfer.
- Uniform thrust is exerted on the disc or rotor.

Applying conservation of mass to this control volume, the mass flow rate (the mass of fluid flowing per unit time) is given by:

$$\dot{m} = \rho A_1 v_1 = \rho S v = \rho A_2 v_2 \tag{9.7.521}$$

where v_1 is the speed in the front of the rotor, v_2 is the speed downstream of the rotor, v is the speed at the fluid power device, ρ is the fluid density, the area of the turbine is given by S, and A_1 and A_2 are the areas of the fluid before and after reaching the turbine.

So the density times the area and speed should be equal in each of the three regions: before, while going through the turbine and afterwards!

The force exerted on the wind by the rotor is the mass of air multiplied by its acceleration. In terms of the density, surface area and velocities, this can be written as:

$$F = ma = m\frac{\mathrm{d}v}{\mathrm{d}t} = \dot{m}\Delta v = \rho S v\left(v_1 - v_2\right) \tag{9.7.522}$$

The work done by the force may be written incrementally as:

$$\mathrm{d}E = F\mathrm{d}x \tag{9.7.523}$$

and the power (rate of work done) of the wind is (the reader must try to not confuse the P of the Power used here with the P of pressure...):

$$P = \frac{\mathrm{d}E}{\mathrm{d}t} = F\frac{\mathrm{d}x}{\mathrm{d}t} = Fv \tag{9.7.524}$$

Now substituting the force F computed above into the power equation will yield the power extracted from the wind:

$$P = \rho S v^2\left(v_1 - v_2\right) \tag{9.7.525}$$

However, power can be computed another way, by using the kinetic energy. Applying the conservation of energy equation to the control volume yields:

$$P = \frac{\Delta E}{\Delta t} = \frac{1}{2}\dot{m}\left(v_1^2 - v_2^2\right) \tag{9.7.526}$$

Looking back at the continuity equation, a substitution for the mass flow rate yields:

$$P = \frac{1}{2}\rho S v\left(v_1^2 - v_2^2\right) \tag{9.7.527}$$

Both of these expressions for power are completely valid, one was derived by examining the incremental work done, and the other by the conservation of energy. Equating these two expressions yields:

$$P = \frac{1}{2}\rho S v\left(v_1^2 - v_2^2\right) = \rho S v^2\left(v_1 - v_2\right) \tag{9.7.528}$$

For all v and S the density cannot be 0. Examining the two equated expressions yields an interesting result, namely:

$$\frac{1}{2}\left(v_1^2 - v_2^2\right) = \frac{1}{2}\left(v_1 - v_2\right)\left(v_1 + v_2\right) = v\left(v_1 - v_2\right) \tag{9.7.529}$$

or:

$$v = \frac{1}{2}\left(v_1 + v_2\right) \tag{9.7.530}$$

Therefore, the wind velocity at the rotor may be taken as the average of the upstream and downstream velocities.

Returning to the previous expression for power based on kinetic energy:

$$\begin{aligned} P &= \frac{1}{2}\dot{m}\left(v_1^2 - v_2^2\right) = \frac{1}{2}\rho S v\left(v_1^2 - v_2^2\right) = \frac{1}{4}\rho S\left(v_1 + v_2\right)\left(v_1^2 - v_2^2\right) \\ &= \frac{1}{4}\rho S v_1^3\left(1 - \left(\frac{v_2}{v_1}\right)^2 + \left(\frac{v_2}{v_1}\right) - \left(\frac{v_2}{v_1}\right)^3\right) \end{aligned} \tag{9.7.531}$$

By differentiating P with respect to $\frac{v_2}{v_1}$ for a given fluid speed v_1 and a given area S, one finds the maximum or minimum value for P:

$$P_{\max} \Rightarrow \frac{\partial P}{\partial(v_2/v_1)} = \frac{1}{4}\rho S v_1^3 \left(-2\frac{v_2}{v_1} + 1 - 3\left(\frac{v_2}{v_1}\right)^2\right) = 0 \tag{9.7.532}$$

Therefore:

$$-2\frac{v_2}{v_1} + 1 - 3\left(\frac{v_2}{v_1}\right)^2 = 0 \tag{9.7.533}$$

Hence:

$$3\left(\frac{v_2}{v_1}\right)^2 + 2\frac{v_2}{v_1} - 1 = 0 \tag{9.7.534}$$

This is an equation of the second degree in $v_2/v1$ that is solved easily... The solutions are:

$$\left(\frac{v_2}{v_1}\right)_{1,2} = \frac{-2 \pm \sqrt{2^2 - 4\cdot 3\cdot(-1)}}{2\cdot 3} = \frac{-2 \pm \sqrt{16}}{6} = \{1/3, -1\} \tag{9.7.535}$$

Practical considerations lead us to reject the negative solution. Therefore we keep only:

$$P_{\max} \Rightarrow \frac{v_2}{v_1} = \frac{1}{3} \tag{9.7.536}$$

Therefore:

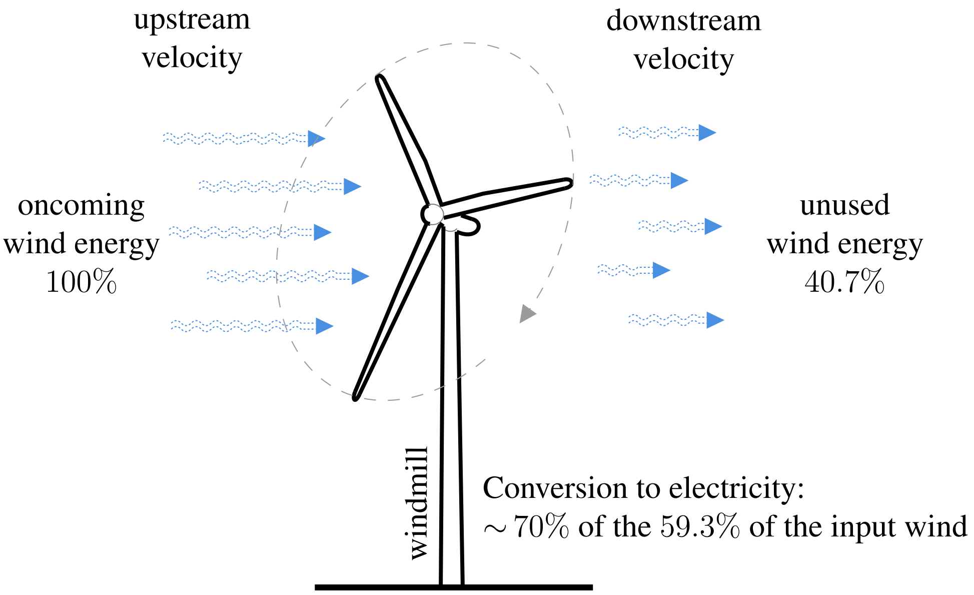
$$\begin{aligned} P_{\max} &= \frac{1}{4}\rho S v_1^3 \left(1 - \left(\frac{v_2}{v_1}\right)^2 + \left(\frac{v_2}{v_1}\right) - \left(\frac{v_2}{v_1}\right)^3\right) \\ &= \frac{1}{4}\rho S v_1^3 \left(1 - \frac{5}{27}\right) = \frac{1}{4}\rho S v_1^3 \frac{32}{27} = \frac{8}{27}\rho S v_1^3 \end{aligned} \tag{9.7.537}$$

Hence:

$$\frac{\text{Max power extracted}}{\text{Max power available}} = \frac{\frac{8}{27}\rho S v_1^3}{\frac{1}{2}\rho S v_1^3} = \frac{16}{27} \cong 0.593 = 59.3\% := C_p \tag{9.7.538}$$

C_p is referred to as the "Betz's limit" and states that the maximum power an ideal rotor can extract from wind is 59.3%.

An ideal rotor of the type described above is named an "actuator disk". The actuator disk induces a reduction of the free-stream wind speed.



This is an important limit because it defines the upper limit of the efficiency of any rotor disk type energy extracting device that is placed in the flow of a fluid. A large fraction of the 59.3% of total wind energy that is extracted from wind is transferred to the turbine, but some of it is used to overcome viscous drag on blades and generate vortices in the wake. Within the turbine, most of the energy is converted into useful electrical energy, while some of it is lost in gearbox, bearings, generator, power converter, transmission and others. Most practical rotors with three blades reach an overall efficiency of about 50%.

Often, inventors claim to have developed a rotor that achieves an efficiency that is greater than 59.3%; such claims are suspect and must be analysed. There are turbine configurations that may violate the Betz limit.

✍**Example:**

Let us consider a wind turbine with a rotor diameter of $70\,[\text{m}]$ and assume that $v_1=12\,[\text{m}\cdot\text{s}^{-1}]$ with air density of $1.225\,[\text{kg}\cdot\text{m}^{-3}]$. Therefore:

$$P_{\text{Betz}}(v_1)=\frac{16}{27}\frac{\rho S v_1^3}{2}=\frac{16}{27}\frac{1.225\pi\left(\frac{70}{2}\right)^2 12^3}{2}=2.4\,[\text{MW}]$$

For more information about this result and its implications, the reader can refer to the excellent textbooks [285].

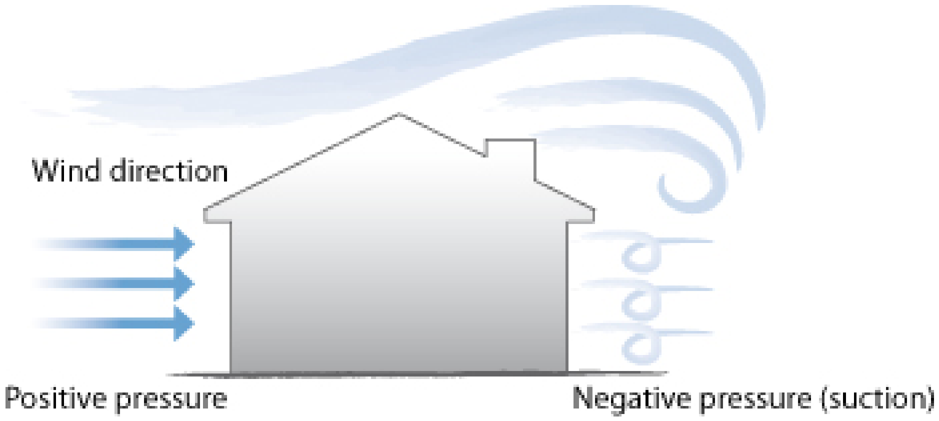
Remark

In the technical field study of pumps, tires or compressed air tanks, we measure the pressure with "manometers" whose zero corresponds to the atmospheric pressure.

9.7.2.4.7.1 Wind pressure

The "wind pressure", alos named "velocity pressure", is the total force exerted upon a structure by wind.

For a flat surface it consists of two factors, the first being the dynamic pressure exerted on the windward side of the surface (i.e. wind load). This is equal to $(1/2)\rho v^2$ as seen just earlier above[37], where ρ is the air density and v is the wind speed normal to the surface. The second factor is the pressure decrease, or "suction", produced on the leeward side of the surface (that latter is often forgotten as many beginners consider that wall as having a infinite surface size), which is equal to $(1/2)C\rho v^2$, where C is a structural constant varying from -0.3 for cylindrical objects to 1.0 for long plates (see page 3856 for the derivation of this force).



The wind pressure P is the sum of these two, explicitly:

$$P_{\text{wind}} = \frac{1}{2}(1+C)\rho v^2 \tag{9.7.539}$$

This formula should be used with caution. The actual wind pressure depends on the shape of the object and the nature of the environment. For objects not presenting a flat surface to the wind, such as bridges and chimneys, complicating aerodynamic factors are introduced that make the above formula invalid.

If we just want a lower bound (lower limit) we can get rid of the drage force to get:

$$P_{\text{wind,LL}} = \frac{1}{2}\rho v^2 \tag{9.7.540}$$

If we consider that the Betz's limit may apply to any flat obstacle, we could we even write:

$$P_{\text{wind}} = \frac{1}{2}(C_p+C)\rho v^2 \tag{9.7.541}$$

Therefore a theoretical lower bound would be:

$$P_{\text{wind,LL}} = \frac{1}{2}C_p\rho v^2 \tag{9.7.542}$$

---

[37] Dynamic pressure based on $(1/2)\rho v^2$ is for incompressible flow. It quickly becomes meaningless above Mach 0.3.

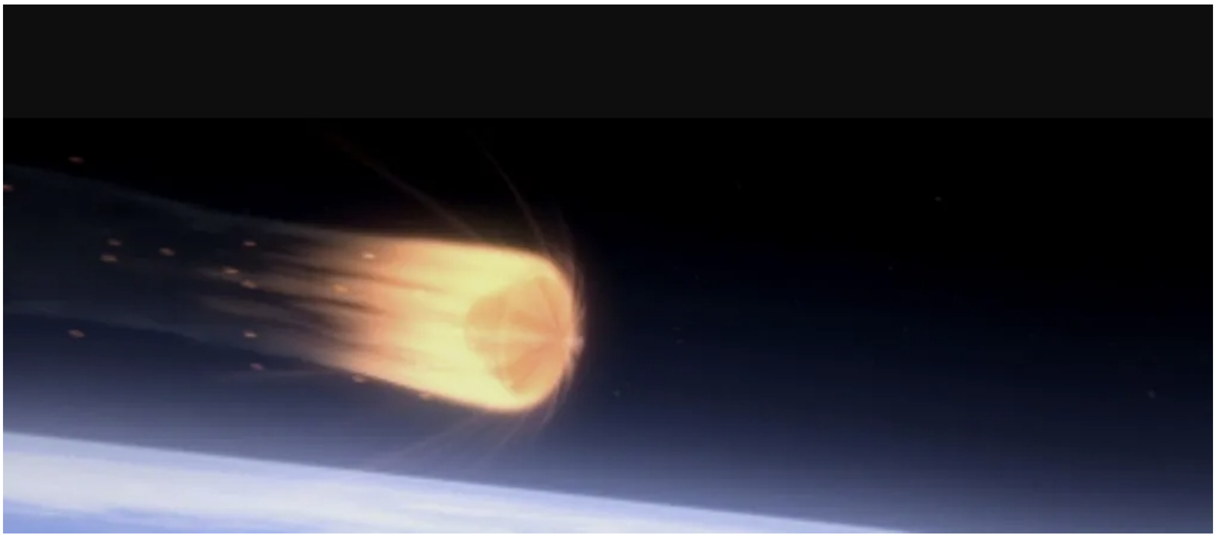
✍**Example:**

What is the lower bound force of a wind with a speed of $100\,[\text{km}\cdot\text{h}^{-1}]$ (i.e. $27.8\,[\text{m}\cdot\text{s}^{-1}]$) on a 20 square meter wall given the air density is $1.225\,[\text{kg}\cdot\text{m}^{-3}]$ and $C_p = 0.593$?

The solution is simply given by:

$$F_{\text{wind,LL}} = P_{\text{wind,LL}} \cdot S = \frac{1}{2}C_p\rho v^2 S \cong 5614\,[\text{N}]$$

We can't apply the calculations above (as far as we know) to compute the thermal shield temperature of a spacecraft that re-enters Earth's atmosphere deriving the encountered pressure at a typical speed of $28,000\,[\text{km}\cdot\text{h}^{-1}]$ (i.e. $7,777\,[\text{m}\cdot\text{s}^{-1}]$) with a thermal shield with a diameter of $3.3\,[\text{m}]$ with a $C = -0.2$ at a height of $80\,[\text{km}]$ (corresponding to an air density of approximately $3\cdot 10^{-5}\,[\text{kg}\cdot\text{m}^{-3}]$) as we don't know on which volume the result should be applied to!



By re-entering atmosphere spaceship transfers it's kinetic energy to impacting air molecules, thus molecules starts to move at a spaceship speed too. Knowing average molecules speed (which would be an aircraft speed) we can calculate shock-wave zone gas temperature (see section Statistical Mechanics page 3558):

$$T = \frac{m\bar{v}^2}{3k} \tag{9.7.543}$$

Typical re-entry speed of Space Shuttle is about $7,823\,[\text{m}\cdot\text{s}^{-1}]$, this gives shock zone temperature $\sim 68,000$ [K] that seems more than enough to heat Nitrogen into a plasma...!? Obviously the last relation is not accurate as if you apply it for commercial airplanes you would get a temperature of ~ 70 [K], for the Concorde at Mach 2 you would get ~ 490 [K] and for the SR-71 Blackbird you would get $\sim 1,000$ [K]...

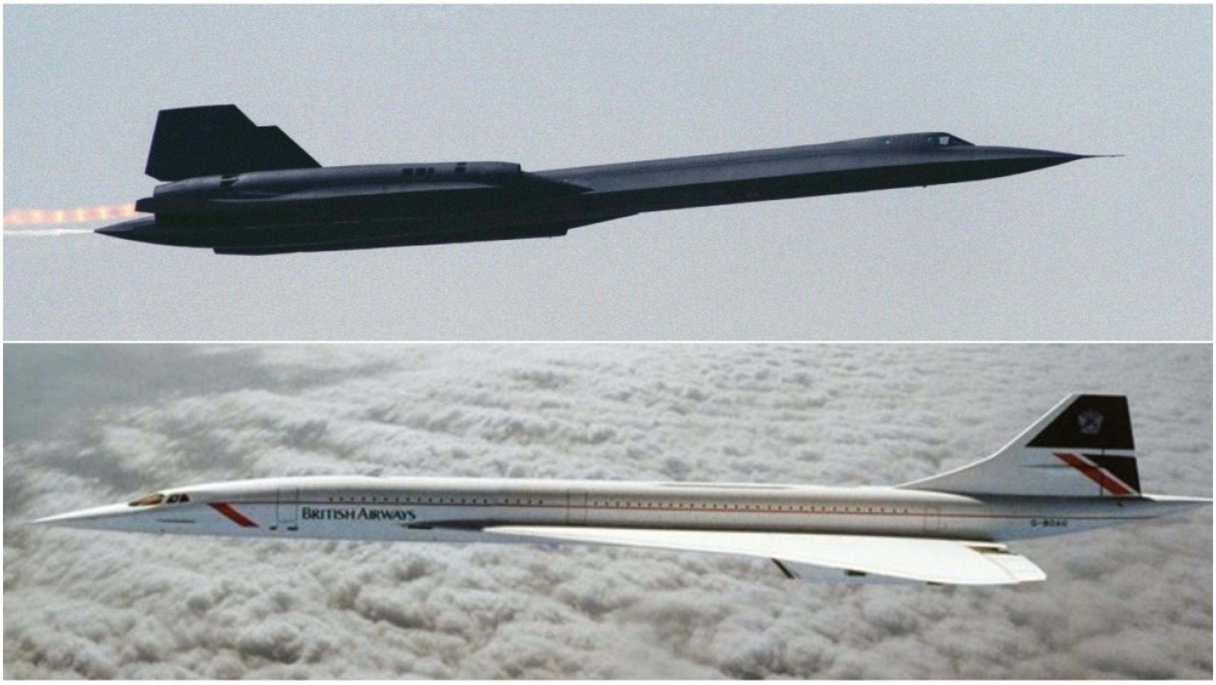


Figure 9.258: **SR-71 Blackbird on the top and Concorde on the bottom**

The reason why the spacecraft itself doesn't heat up at this temperature is that spacecrafts are protected with a heat shield composed of layers from special materials dissipating heat received. Also there's an ablative (process that utilizes a sacrificial liner which cools something through chemical reactions and the enthalpy of vaporization) cooling mechanism in action and besides at these altitudes air density is very small, so heat is transferred from plasma to spacecraft at low rates.

FDM simulations (see section Numerical Methods page 6752) show the air in the bow shock of the stardust probe reaches temperatures of around $50,000$ [K] at 71 [km] altitude, falling to $10,000$ [K] at 51 [km].

9.7.2.5 Levelling law

We will prove now that a fluid (gas or liquid) will be levelled if and only if it is a stationary compressible inviscid fluids in a gravitational potential with an isobaric surface.

As proven at page 3830, the Navier-Stokes equation can be written as:

$$\rho\left[\partial_t\vec{v}+(\vec{v}\circ\vec{\nabla})\vec{v}\right]=\rho\vec{f}-\vec{\nabla}p \tag{9.7.544}$$

Let us consider a stationary and incompressible fluid[38] (hydrostatics), where velocity $\vec{v}=0$ everywhere, and all time derivatives are zero $\left(\frac{\partial}{\partial t}=0\right)$. The equation simplifies dramatically to the hydrostatic equation:

$$\vec{\nabla}p=\rho\vec{f} \tag{9.7.545}$$

---

[38] Oceans and seas and rivers are obviously not stationary!

For reminder, that tells us that any internal pressure gradient must perfectly balance the external body forces.

In any standard real-world scenario, the primary body force is gravity. Gravity is a conservative force field, which means it can be expressed as the gradient of a scalar potential function, φ :

$$\vec{f}=-\vec{\nabla}\varphi \tag{9.7.546}$$

Hence:

$$\vec{\nabla}p=-\rho\vec{\nabla}\varphi \tag{9.7.547}$$

For uniform gravity near Earth's surface, $\varphi=gz$, making $\vec{f}=-g\hat{\vec{z}}$.

Now, let's take the curl $(\vec{\nabla}\times)$ of both sides of the equation. A fundamental identity in vector calculus states that the curl of any gradient is zero ($\vec{\nabla}\times(\vec{\nabla}f)=\vec{0}$) (see section Vector Calculus page 1361).

So:

$$\vec{\nabla}\times(\vec{\nabla}p)=\vec{\nabla}\times(-\rho\vec{\nabla}\varphi) \tag{9.7.548}$$

Therefore (as $\vec{\nabla}\times(\vec{\nabla}f)=\vec{0}$) :

$$\vec{0}=-\rho\vec{\nabla}\times(\vec{\nabla}\varphi) \tag{9.7.549}$$

Hence using chain rule:

$$\vec{0}=-\vec{\nabla}\rho\times(\vec{\nabla}\varphi)-\rho(\vec{\nabla}\times\vec{\nabla}\varphi) \tag{9.7.550}$$

Given the identity ($\vec{\nabla}\times(\vec{\nabla}f)=\vec{0}$) and eliminating the -1 factor:

$$\vec{0}=\vec{\nabla}\rho\times(\vec{\nabla}\varphi) \tag{9.7.551}$$

As this proof is for fluids (a gas, a fluid and a plasma are fluids), we reality show us the density is not constant when the fluid is submitted to a gravitation potential. Hence taking the case of compressible fluid the term $\vec{\nabla}\rho$ is not zero!

For $\vec{\nabla}\rho\times(\vec{\nabla}\varphi)$ to be zero the gradient of density $(\vec{\nabla}\rho)$ must be parallel to the gradient of the potential $(\vec{\nabla}\varphi)$. This proves that density layers must align perfectly with the equipotential surfaces under our previous considerations that are based on our observations of reality, i.e.:

$$\rho=\rho(\varphi) \tag{9.7.552}$$

So we have to rewrite:

$$\vec{\nabla}p=-\rho\vec{\nabla}\varphi \tag{9.7.553}$$

as:

$$\vec{\nabla}p=-\rho(\varphi)\vec{\nabla}\varphi \tag{9.7.554}$$

It follows by the chain rule that pressure must also be a strict function of the potential, i.e.:

$$p=p(\varphi) \tag{9.7.555}$$

This means that surfaces of constant potential (equipotentials) are automatically surfaces of constant pressure (isobars) and constant density (isopycnals). So we can obviously rewrite:

$$\vec{\nabla}p(\varphi)=-\rho(\varphi)\vec{\nabla}\varphi \tag{9.7.556}$$

Let's look specifically at the top surface of our stationnary compressible fluid, exposed to the atmosphere!

The atmosphere exerts a uniform ambient pressure (p_{atm}) across the entire open surface. Therefore, the boundary condition for the free surface is:

$$p(x,y,z)=p_{\text{atm}}=c^{te} \tag{9.7.557}$$

Because we established that p is strictly a function of $\varphi(p=p(\varphi))$, if p is constant across the surface, then φ must also be constant across the surface:

$$\varphi(x,y,z)=C^{te} \tag{9.7.558}$$

Where for reminder and by definition, a surface where $\varphi=C^{te}$ is an "equipotential surface".

If we take a small displacement vector $\mathrm{d}\vec{r}=(\mathrm{d}\vec{x},\mathrm{d}\vec{y},\mathrm{d}\vec{z})$ tangent to the fluid (gas, liquid, plasma) surface, the change in potential along the surface must be zero:

$$\vec{\nabla}\varphi\circ\mathrm{d}\vec{r}=0 \tag{9.7.559}$$

Because the dot product is zero, the force vector $\vec{f}$ (which points in the direction of $-\nabla\varphi$ by definition) is strictly perpendicular to the fluid surface at every single point!

If the surface were tilted or wavy, $\vec{\nabla}\varphi\circ\mathrm{d}\vec{r}$ would not be zero. Gravity would have a parallel component along the slope, creating a shear stress that forces the fluid to flow until it flattens out.

Mathematically, a conclusion, a fluid surface will be perfectly level if:

- We have an inviscid fluid (with no viscosity)
- We have a stationary fluid (that never happens in reality)
- The pressure gradient is aligned with gravity (that almost never happens in reality)
- Isobaric lines matches with equipotential of the gravitational field

On a localized scale, this is presented as a very good apparent flat plane with human eye (but not with precision instruments as we would always measure at tiny curvature even in an Olympic swimming pool for example). On a planetary scale, this equipotential surface curves with the planet's mass, forming almost a perfect spherical geoid.

9.7.2.6 Hydrostatic Pressure

We have previously demonstrated without difficulty that:

$$P = -z\rho g - \frac{1}{2}\rho v^2 - c^{te} \tag{9.7.560}$$

If the fluid velocity is zero:

$$P = -z\rho g - c^{te} \tag{9.7.561}$$

This gives in differential form:

$$\frac{\mathrm{d}P}{\mathrm{d}z} = -\rho g \tag{9.7.562}$$

If we measure the liquid pressure from its upper area z_0:

$$\int_{z_0}^{z} \mathrm{d}P = P = -\int_{z_0}^{z} \rho g \mathrm{d}z = -(z\rho g - z_0\rho g) + c^{te} \tag{9.7.563}$$

If we take z_0 as a reference, we can put that:

$$h = z_0 - z \tag{9.7.564}$$

hence:

$$P = c^{te} + \rho g h \tag{9.7.565}$$

If we find ourselves in the case of a receptacle filled with a fluid in contact with the atmosphere, in order to calculate the pressure in this fluid at a given height h, we should take in consideration the atmospheric pressure, which also is "put" on the fluid. Thus, the "hydrostatic pressure" is given by:

$$P = P_0 + h\rho g \tag{9.7.566}$$

The consequence of this relation is that in a liquid at rest, homogeneous, the equipotential gravific lines are confused with isobaric surfaces. Otherwise, there would be transverse movements.

From this relation we can calculate the famous "water pump suction limit". Using:

$$h_{\max} = \frac{P - \overbrace{P_0}^{=0}}{\rho \cdot g} = \frac{P}{\rho g} = 10.34\,[\mathrm{m}] \tag{9.7.567}$$

The reader must keep in mind that the tube is only subjected to a partial vacuum (just like a real-world pump produces), the pressure differential is less, meaning that the water is "raised" or "lifted" up the tube to a reduced height of typically 7 to 8 meters.

Remark

In the technical field study of pumps, tires or compressed air tanks, we measure the pressure with "manometers" whose zero corresponds to the atmospheric pressure.

Finally here are some common drag coefficient values (most model names are based on the Gregorian calendar):

C_D	**Item**
0.001	Laminar flat plate parallel to the flow (Re<10^6)
0.005	Turbulent flat plate parallel to the flow (Re>10^6)
0.021	F-4 Phantom II (subsonic)

9.7.2.7 Archimedes' principle

The Archimedes' principle, almost worldwide known phenomenon ..., is often rebellious to the first intuition. By the way, we have too much tendency in schools to present the Archimedes force as a "principle" and this wrongly because a simple mathematical analysis is enough to prove it.

Indeed, if we isolate an arbitrary portion ΔV of a fluid in static equilibrium, the conditions of this equilibrium are necessarily written (otherwise the volume dissociates and is no longer in static equilibrium):

$$\boxed{\vec{P}+\oint(\vec{n}p)\mathrm{d}S=\vec{0}} \tag{9.7.568}$$

where P denotes the weight ($\vec{P}=m\vec{a}$ in a first approximation ...) of equation whereas the term equation describes the resultant of the forces of pressure exerted on the surface of equation.

where P denotes the weight ($\vec{P}=m\vec{a}$ in a first approximation ...) of ΔV whereas the term $\oint(\vec{n}p)\mathrm{d}S$ describes the resultant of the forces of pressure exerted on the surface of ΔV

Each surface element $\mathrm{d}S$ therefore undergoes a force:

$$\vec{F}_{\rightarrow\mathrm{d}S}=(\vec{n}p)\mathrm{d}S \tag{9.7.569}$$

where p is the pressure applied locally on $\mathrm{d}S$. And for $\vec{n}$, we know that it is a unit vector directed normally (at the perpendicular) of $\mathrm{d}S$ but this time towards the interior of ΔS. The resultant of all these forces is denoted historically as follows:

$$\vec{F}_A=\oint(\vec{n}p)\mathrm{d}S \tag{9.7.570}$$

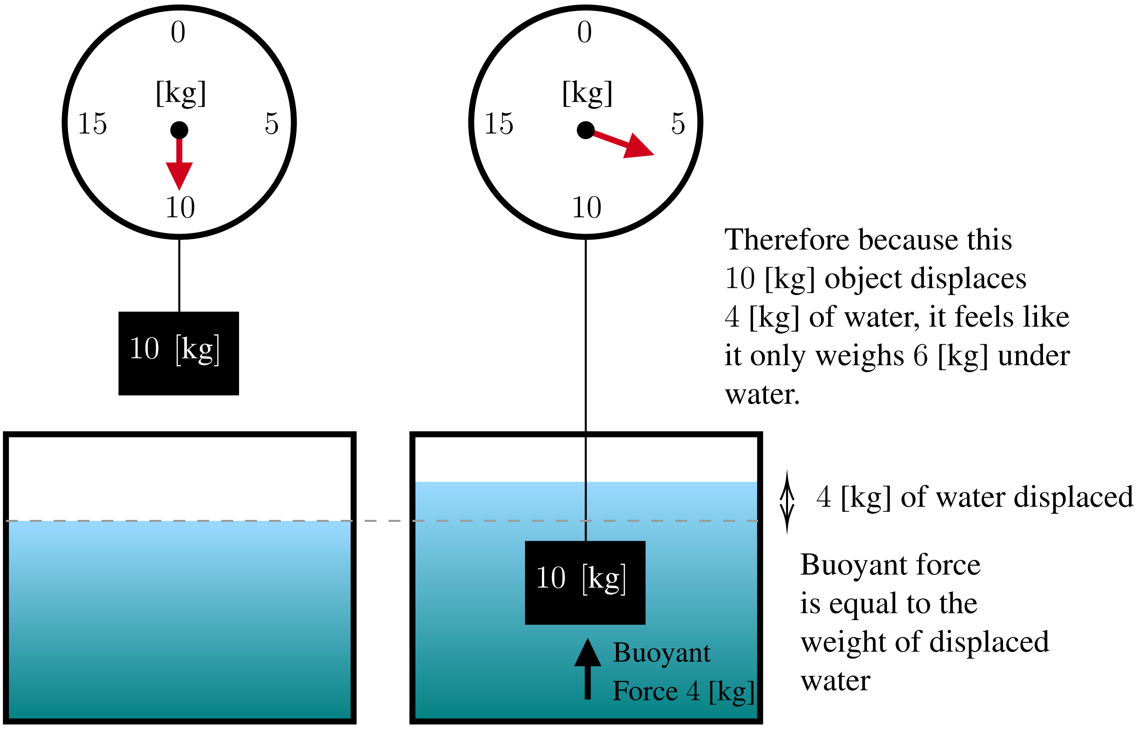
which therefore expresses, as you can guess, the famous "Archimedes' force" that the rest of the fluid exerts on the element. The integral bears on the whole surface (this surface is closed, hence the corresponding curvilinear integral) of the element ΔV.

The equilibrium condition therefore requires that:

$$\vec{F}_A=-\vec{P} \tag{9.7.571}$$

We easily understand that $\vec{F}_A$ is directed upwards: under the effect of the gravitational field and therefore p increases with depth.

If we replace the fluid contained in the volume with any fluid or solid object but that occupies the same volume, the Archimedes' force is not altered. Because of the relation $\vec{F}_A=-\vec{P}$ we are accustomed to say that it is equivalent to the weight of the displaced fluid.



0
[kg]
15
5
10
10 [kg]
0
[kg]
15
5
10
Therefore because this 10 [kg] object displaces 4 [kg] of water, it feels like it only weighs 6 [kg] under water.
4 [kg] of water displaced
10 [kg]
Buoyant Force 4 [kg]
Buoyant force is equal to the weight of displaced water

Figure 9.259: **Archimedes principle**

In other words, for an object floating on a liquid surface (like a boat) or floating submerged in a fluid (like a submarine in water or dirigible in air) the weight of the displaced liquid equals the weight of the object.

In the case where the direction and the intensity in time of $\vec{g}$ are uniform and constant we can write:

$$F_A = -P = \int\limits_{\Delta V} \rho g \mathrm{d}V = \rho g V \tag{9.7.572}$$

and we find again the relation of the "Archimedes' law" well known to all schoolchildren:

$$\boxed{F_A = \rho g V} \tag{9.7.573}$$

There is another possibility to arrive at this proof which requires fewer mathematical tools and is therefore more affordable:

For this let us consider a cylinder of volume V immersed in a liquid at the vertical. The horizontal components of the pressure forces vanish, but the vertical component P_1 at the top of the cylinder (close to the surface) is less in intensity (except external cause) than that at its base P_2 We can therefore write:

$$F_A = (P_2 - P_1)S = (h_2 \rho g - h_1 \rho g)S = \Delta h S \rho g = V \rho g \tag{9.7.574}$$

It is a bit simpler and it keeps in a single line without integrals...

The most general and beautiful proof of the Archimedes principle relies on Gauss' gradient theorem (see section Vector Calculus page 1882) given for recall by:

$$\oiint_S f \mathrm{d}\vec{S} = \iiint_V \vec{\nabla}(f) \mathrm{d}V \tag{9.7.575}$$

That we will rewrite here as:

$$\oint_{\partial V} p(\vec{r})\mathrm{d}\vec{A} = \int_V \vec{\nabla} p(\vec{r})\mathrm{d}V \tag{9.7.576}$$

Now, as the position-dependent function we choose the pressure:

$$p(\vec{r}) = p_0 - \rho g z \tag{9.7.577}$$

where z is the vertical position coordinate and p_0 is the pressure at zero-level $(z = 0)$. We need a minus sign here, because pressure increases when going down in the liquid (i.e. in negative z direction).

Then de gradient is:

$$\vec{\nabla} p(\vec{r}) = -\rho g \hat{z} \tag{9.7.578}$$

where $\hat{z}$ is the unit-vector in z-direction (i.e. upwards).

Inserting the latter into to Gauss' gradient theorem, we get:

$$\oint_{\partial V} p(\vec{r})\mathrm{d}\vec{A} = \int_V (-\rho g \hat{z})\mathrm{d}V \tag{9.7.579}$$

Now on the left side $p\mathrm{d}\vec{A}$ obviously is the pressure force acting on the surface area element $\mathrm{d}\vec{A}$ (except for a minus sign, because the force element $\mathrm{d}\vec{F}$ points inside the body, while the area element $\mathrm{d}\vec{A}$ points outside). And on the right side, the constants ($-\rho g \hat{z}$) can be factored out. So we get:

$$-\oint_{\partial V} \mathrm{d}\vec{F} = -\rho g \hat{z} \int_V \mathrm{d}V \tag{9.7.580}$$

or finally:

$$\vec{F} = \rho g \hat{z} V \tag{9.7.581}$$

This is just Archimedes' principle (buoyant force is pointing upwards and equal to the weight of the displaced liquid)!

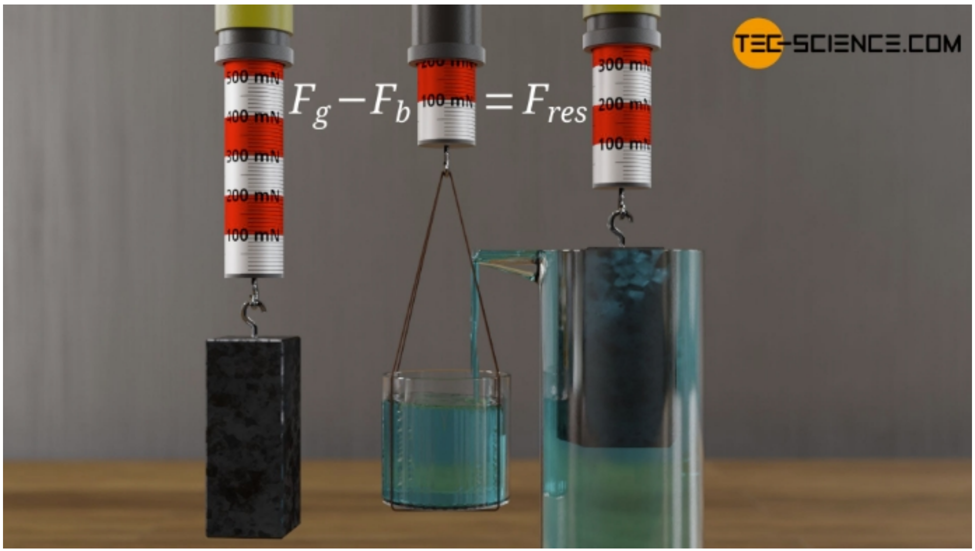


Figure 9.260: **Demonstration of the Archimedes' principle (source:** `https://www.tec-science.com`**)**

Let us derive now the Archimedes principle for a sphere with direct hydrostatic pressure calculation for the fun and the beauty!

We will need to integrate the pressure at each position to recover Archimedes law, using the fact that at a given height the pressure is $p(z)=\rho g z$ where ρ is the water's density.

First of all, we have the weight of the sphere (with density ρ_s) which gives:

$$F_w=-mg=-\rho_s\frac{4}{3}\pi R^3 g \qquad (9.7.582)$$

pointed towards the bottom (minus sign). This is the first force acting on the sphere, we will need it later.

On the other hand, the force due to hydrostatic pressure is:

$$p(z)=\rho g(R-z) \qquad (9.7.583)$$

where z is the height. We set $z=0$ at the equatorial plane, which will be useful later on when we go to spherical coordinates, so that $p(z=R)=0$ at the north pole of the sphere and the pressure grows towards the bottom of the sphere, reaching $p(z=-R)=\rho g 2R$ at south pole (towards the top). We can always set the z where we want as this simply yields an extra constant external pressure p_0 which balances on the top and bottom, so we neglect it.

The pressure acting on the sphere is directed radially (it's actually directed isotropically, but only the radial part acts on the sphere).

This means that the force due to water acting on an infinitesimal surface of the sphere $\mathrm{d}A$ is given by:

$$\mathrm{d}F=p(z)\mathrm{d}A \qquad (9.7.584)$$

and we can write:

$$\mathrm{d}A=R^2\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi \qquad (9.7.585)$$

using spherical coordinates. θ is the angle with the vertical, as usual convention, with $\theta=0$ being the north pole and $\theta=\pi$ the south pole.

Because we are only interested in the z direction we only consider the part of the force directed along the z direction (the other components disappear by symmetry as they all are on the same z level).

So we only need:

$$\mathrm{d}F_z=\mathrm{d}F\cos(\theta) \qquad (9.7.586)$$

where, as before, θ is the angle with respect to the vertical director. At $\theta=0$ (north pole) the force pushes towards the bottom.

Now we integrate on the sphere only along θ as the force does not depend on ϕ. The integral on ϕ gives us a 2π factor:

$$F_z=\int\limits_0^{2\pi}\int\limits_0^{\pi}\mathrm{d}F_z=\int\limits_0^{2\pi}\int\limits_0^{\pi}\mathrm{d}F\cos(\theta)=2\pi\int\limits_0^{\pi}p(z)\mathrm{d}A(\theta)\cos(\theta) \qquad (9.7.587)$$

where $\mathrm{d}A$ has already been integrated in ϕ.

Putting all together and using $z=R\cos(\theta)$ and[39] $\mathrm{d}A(\theta)=R^2\sin(\theta)\mathrm{d}\theta$ (see section Differential and Integral Calculus page 1524) we get:

$$\begin{aligned}F_z&=2\pi\int_0^{\pi}\rho g(z-R)R^2\sin(\theta)\cos(\theta)\mathrm{d}\theta\\&=2\pi\int_0^{\pi}\rho g(R\cos(\theta)-R)R^2\sin(\theta)\cos(\theta)\mathrm{d}\theta\end{aligned}\tag{9.7.588}$$

which we then rewrite as:

$$F_z=2\pi\int_0^{\pi}\rho gR(\cos(\theta)-1)R^2\sin(\theta)\cos(\theta)\mathrm{d}\theta\tag{9.7.589}$$

and so:

$$F_z=2\pi R^3\rho g\int_0^{\pi}(\cos(\theta)-1)\sin(\theta)\cos(\theta)\mathrm{d}\theta\tag{9.7.590}$$

The integral is not that hard. Indeed, let us substitute $u=\cos(\theta)\longrightarrow\mathrm{d}u=-\sin(\theta)\mathrm{d}\theta$, therefore:

$$\begin{aligned}\int_0^{\pi}(\cos(\theta)-1)\sin(\theta)\cos(\theta)\mathrm{d}\theta&=-\int_0^{\pi}(u-1)u\mathrm{d}u=-\int_0^{\pi}\left(u^2-u\right)\mathrm{d}u=-\int_0^{\pi}u^2\mathrm{d}u+\int_0^{\pi}u\mathrm{d}u\\&=-\frac{u^3}{3}+\frac{u^2}{2}\bigg|_0^{\pi}=-\frac{\cos^3(\theta)}{3}+\frac{\cos^2(\theta)}{2}\bigg|_0^{\pi}\\&=\left(\frac{1}{3}+\frac{1}{2}\right)-\left(-\frac{1}{3}+\frac{1}{2}\right)=\frac{2}{3}\end{aligned}\tag{9.7.591}$$

So we get:

$$\int_0^{\pi}(\cos(\theta)-1)\sin(\theta)\cos(\theta)\mathrm{d}\theta=\frac{2}{3}\tag{9.7.592}$$

and this means:

$$F_z=2\pi R^3\rho g\int_0^{\pi}(\cos(\theta)-1)\sin(\theta)\cos(\theta)\mathrm{d}\theta=\frac{4}{3}\pi R^3\rho g\tag{9.7.593}$$

Which means that the total force acting on the sphere, is:

$$F_b=F_w+F_z=-\rho_s\frac{4}{3}\pi R^3+\frac{4}{3}\pi R^3\rho g=(\rho-\rho_s)\,\frac{4}{3}\pi R^3\tag{9.7.594}$$

---

[39] Remember that the spherical surface element is $\mathrm{d}A=R^2\sin(\theta)\mathrm{d}\theta\mathrm{d}\phi$ but as the force doesn't depend of ϕ the term $\mathrm{d}\phi$ is unnecessary.

i.e. Archimedes law: the sphere weight minus the equivalent weight in water!

It should be remembered that the Archimedes principle is a force which applies to fluids and therefore also to gases. It is thus thanks to Archimedes' force that a hot air balloon or an airship can rise in the air (in both cases, a gas of lower density than air is used, eg. heated air or helium).

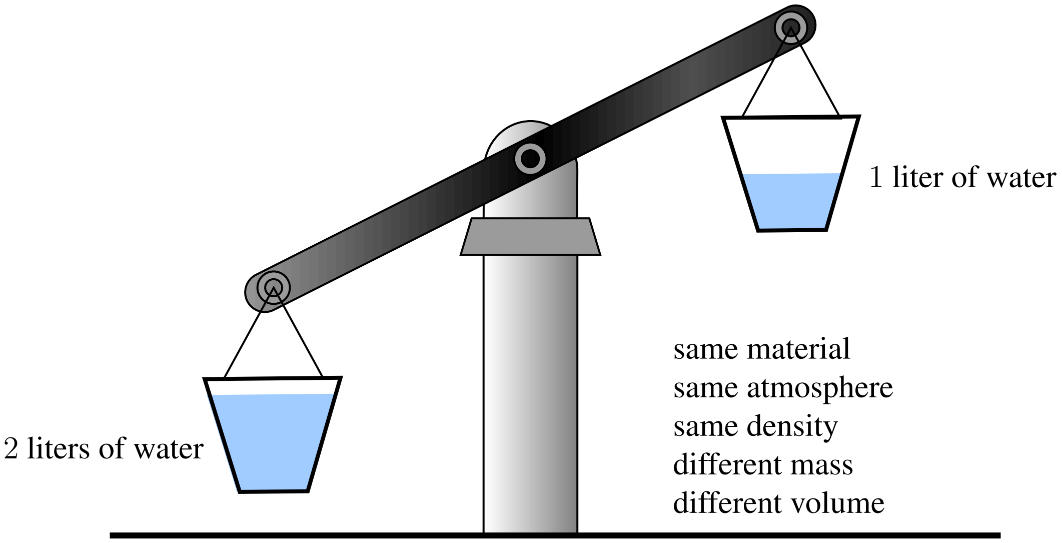
Figure 9.261: **The hot air inside these balloons is less dense than the surrounding cool air. This results in a buoyant force that causes the balloons to rise when their guy lines are untied (source: Anthony Quintano)**

It is also funny, after the proof of the law of perfect gases (see below), to determine the pressure that our atmosphere should have to have the same density as water and so that a human can then float in the air...

The weightings that are made on a balance will, of course, give the weight in air in most laboratories. When an object displaces its volume in air, it will be buoyed up by the weight of air displaced according to Achimedes's principle. The density of air is 0.0012 [g] (1.2 [mg]) per millilitre. If the density of the weights and the density of the object being weighed are the same, then they will be buoyed up by the same amount, and the recorded weight will be equal to the weight in a vacuum, where there is no buoyancy. If the densities are markedly different, the differences in the buoyancies will lead to a small error in the weighing: One will be buoyed up more than the other, and an unbalance will result. Such a situation arises in the weighing of very dense objects [e.g., platinum vessels (density = 21.4) or mercury (density=13.6)] or light, bulky objects [e.g., water (density $\cong 1$)]; and in very careful work, a correction should be made for this error.

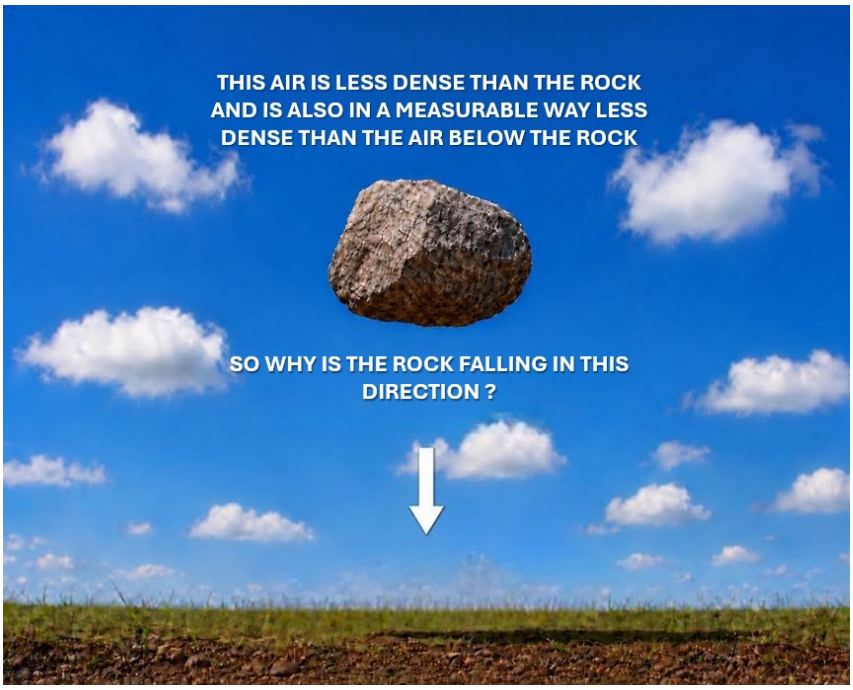
Note that in most cases, a correction is not necessary because the error resulting from the buoyancy will cancel out in percent composition calculations. The same error will occur in the numerator (as the concentration of a standard solution or weight of a gravimetric precipitate) and in the denominator (as the weight of the sample). Of course, all weightings must be made with the materials in the same type of container (same density) to keep the error constant. Furthermore for most objects weighed, buoyancy errors can be neglected as they are only about one part per thousand!

We know experimentally and theoretically that object falls down because of Earth's gravitational attraction (in the point of view of Newtonian gravity). But some uneducated people claim that an object falls down due to its density, not gravity.



1 liter of water
2 liters of water
same material
same atmosphere
same density
different mass
different volume

By putting two objects of an equal density & different mass against each other using a balance like in the figure above, it is easy to see that the object's density is not the reason it falls down. Or more absurd as depicted in the image below:



THIS AIR IS LESS DENSE THAN THE ROCK AND IS ALSO IN A MEASURABLE WAY LESS DENSE THAN THE AIR BELOW THE ROCK
SO WHY IS THE ROCK FALLING IN THIS DIRECTION ?

9.7.2.8 Surface tension

"Surface tension" is the tendency of liquid surfaces at rest to shrink into the minimum surface area possible. Surface tension is what allows objects with a higher density than water such as razor blades and insects (e.g. water striders) to float on a water surface without becoming even partly submerged.

Because of the relatively high attraction of water molecules to each other through a web of hydrogen bonds, water has a higher surface tension (72.8 millinewtons [mN] per meter at $20\ [^\circ C]$) than most other liquids. Surface tension is an important factor in the phenomenon of capillarity.

In other words, from an energetic point of view, two interacting molecules always try without external influence to decrease the fluid's energy locally (see section Analytical Mechanics page 3152). Molecules at the surface of the liquid have less opportunity to lower their energy through bonds than molecules in the center of the liquid. The surface of the liquid is therefore a more energetic area than the interior. As any system seeks to have a minimum energy, this surface is reduced to a minimum. In weightlessness, the liquid forms a sphere, which offers a minimal surface area at constant volume (see section Geometric Shapes page 2993). On Earth, under the effect of gravity, the liquid forms a drop, and depending on its affinity with the surface on which it is placed, it spreads more or less, forming a dome, slightly flattened due to gravity.

The energy difference therefore generates forces that keep the fluid in a given geometric configuration; these are the capillary forces that are tangent to the surface. If we consider a portion of the surface, this force is exerted on the contour of the surface and keeps it in a given position. Hence, the surface tension has the dimension of force per unit length and is defined by:

$$\boxed{\gamma=\frac{F_T}{L}} \tag{9.7.595}$$

or of energy per unit area (it is also sometimes denoted T instead of γ). The two are equivalent, but when referring to energy per unit of area, it is common to use the term surface energy, which is a more general term in the sense that it applies also to solids.

For really large volumes of water (if you, for instance, sucked all the water out of the oceans and placed it somewhere far away in space in the standard mad-scientist way), then you also get a sphere, but for a different reason: the mass of water wants to minimize its (self-)gravitational potential energy and this is also done when it is spherical (see section Geometric Shapes page 2993). If such a volume is in the presence of external gravitational field (for instance if it was orbiting the Earth) then it would not be completely spherical: this is one of the reasons the Moon has a slightly odd shape, for instance.

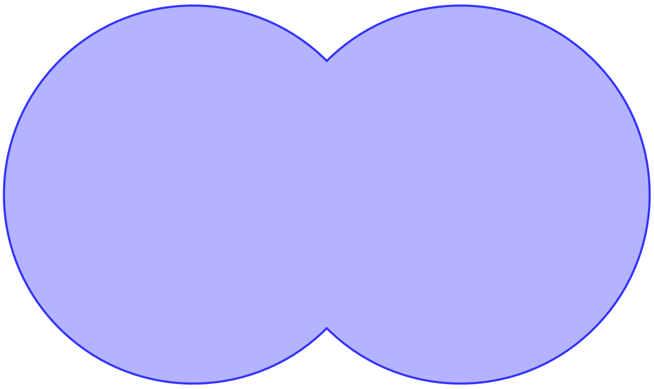
It is interesting to try to quantify the differences between the effects. One way to do this is to consider a spherical ball of water (or anything else, but we will stick to water because it is a very common asked case) and consider what force we would need to bisect the sphere and move the two halves apart. Then we can compute the force that would be needed to break the surface tension, and that needed to overcome the gravitational attraction of the two halves.

Let the radius of the ball be R, and surface tension be γ. So the total force we need to exert when splitting the sphere is simply the total force exerted by surface tension around a circumference of the sphere, and we can see immediately that this goes like R:

$$F_T = 2\pi R\gamma \tag{9.7.596}$$

Let us calculate now the equivalent force caused by gravity.

If we think about the surface which cuts the initial sphere into two hemispheres, then what is preventing the ball collapsing inwards across this surface at equilibrium (if we omit surface tension!) is pressure. So the gravitational force between the two halves of the initial sphere, when they are touching, must be equal to the integral of the pressure over that surface:



Let's assume the density is uniform, which it won't be for really large objects but it will be for reasonably small ones. Then we can work out the gravitational acceleration at radius r from the centre, relying on the shell theorem (see section Astronomy page 5281) and knowing the mass inside r is $m(r) = 4/3\pi r^3$:

$$g(r) = \frac{4\pi}{3}G\rho r \tag{9.7.597}$$

And this gives us the pressure at r, just by integrating g from r to R :

$$p(r_0) = \int\limits_{r_0}^{R} \rho g(r)\mathrm{d}r = \frac{4\pi}{3}G\rho^2 \int\limits_{r_0}^{R} r\mathrm{d}r = \frac{2\pi}{3}G\rho^2\left[R^2 - r_0^2\right] \tag{9.7.598}$$

or:

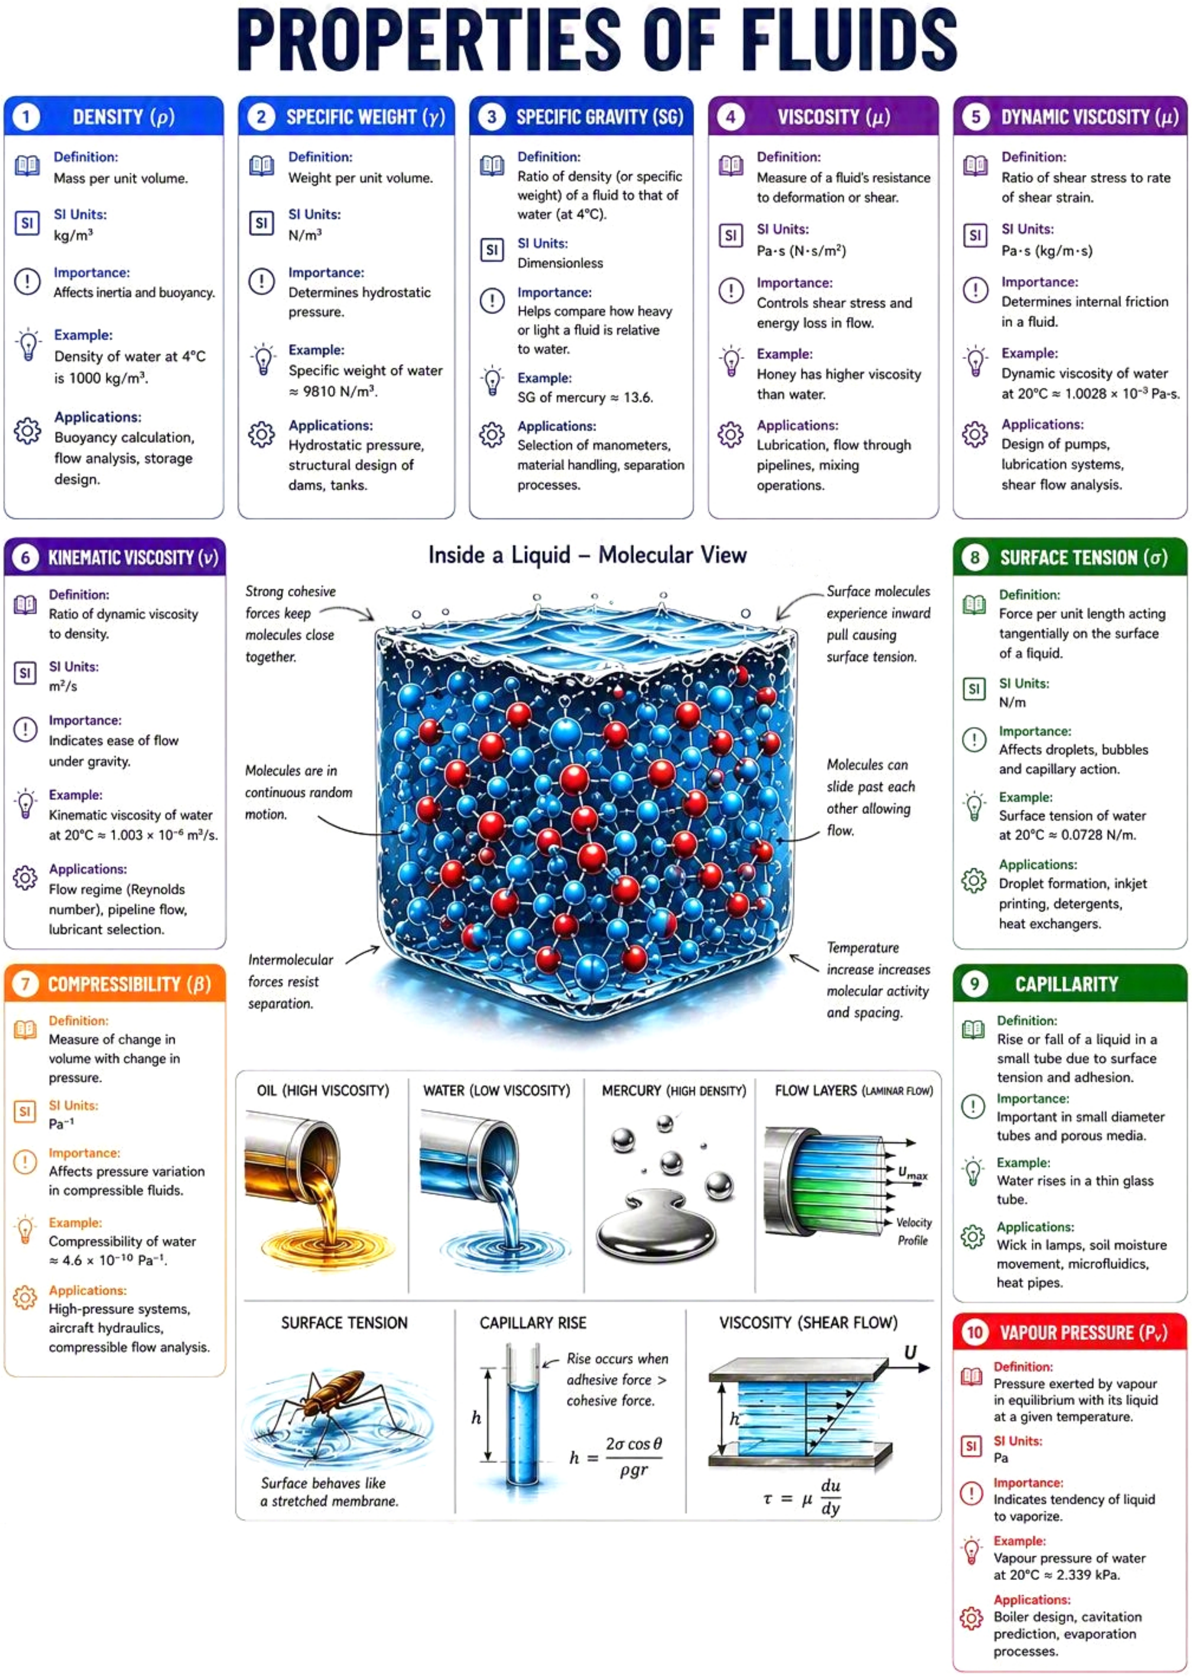
$$p(r) = \frac{2\pi}{3}G\rho^2\left[R^2 - r^2\right] \tag{9.7.599}$$

And finally we can integrate this over the surface to get the total force:

$$F_G = \int\limits_{0}^{R} 2\pi r p(r)\mathrm{d}r = \frac{4\pi^2}{3}G\rho^2 \int_0^R R^2 r - r^3\mathrm{d}r = \frac{\pi^2}{3}G\rho^2 R^4 \tag{9.7.600}$$

So, then, given $\rho = 10^3\,[\mathrm{kg}\cdot\mathrm{m}^{-3}]$ (density of water at ambiant temparature), $G = 6.7\cdot 10^{-11}\,[\mathrm{m}^3\cdot\mathrm{kg}^{-1}\cdot\mathrm{s}^{-2}]$, we can solve for the radius R where $F_T = F_G$, and the answer is about $R \cong 12.8\,[\mathrm{m}]$.

So if this is right, it means that gravity starts beating surface tension for a ball of water which is about 13 [m] in radius.



PROPERTIES OF FLUIDS

1 DENSITY (ρ)

Definition: Mass per unit volume.

SI Units: kg/m^3

Importance: Affects inertia and buoyancy.

Example: Density of water at 4°C is 1000 kg/m^3.

Applications: Buoyancy calculation, flow analysis, storage design.

2 SPECIFIC WEIGHT (γ)

Definition: Weight per unit volume.

SI Units: N/m^3

Importance: Determines hydrostatic pressure.

Example: Specific weight of water $\approx$ 9810 N/m^3.

Applications: Hydrostatic pressure, structural design of dams, tanks.

3 SPECIFIC GRAVITY (SG)

Definition: Ratio of density (or specific weight) of a fluid to that of water (at 4°C).

SI Units: Dimensionless

Importance: Helps compare how heavy or light a fluid is relative to water.

Example: SG of mercury $\approx$ 13.6.

Applications: Selection of manometers, material handling, separation processes.

4 VISCOSITY (μ)

Definition: Measure of a fluid's resistance to deformation or shear.

SI Units: Pa·s (N·s/m^2)

Importance: Controls shear stress and energy loss in flow.

Example: Honey has higher viscosity than water.

Applications: Lubrication, flow through pipelines, mixing operations.

5 DYNAMIC VISCOSITY (μ)

Definition: Ratio of shear stress to rate of shear strain.

SI Units: Pa·s (kg/m·s)

Importance: Determines internal friction in a fluid.

Example: Dynamic viscosity of water at 20°C $\approx 1.0028 \times 10^{-3}$ Pa·s.

Applications: Design of pumps, lubrication systems, shear flow analysis.

6 KINEMATIC VISCOSITY (ν)

Definition: Ratio of dynamic viscosity to density.

SI Units: m^2/s

Importance: Indicates ease of flow under gravity.

Example: Kinematic viscosity of water at 20°C $\approx 1.003 \times 10^{-6}$ m^2/s.

Applications: Flow regime (Reynolds number), pipeline flow, lubricant selection.

7 COMPRESSIBILITY (β)

Definition: Measure of change in volume with change in pressure.

SI Units: Pa^{-1}

Importance: Affects pressure variation in compressible fluids.

Example: Compressibility of water $\approx 4.6 \times 10^{-10}$ Pa^{-1}.

Applications: High-pressure systems, aircraft hydraulics, compressible flow analysis.

Inside a Liquid – Molecular View

Strong cohesive forces keep molecules close together.

Surface molecules experience inward pull causing surface tension.

Molecules are in continuous random motion.

Molecules can slide past each other allowing flow.

Intermolecular forces resist separation.

Temperature increases molecular activity and spacing.

OIL (HIGH VISCOSITY)

WATER (LOW VISCOSITY)

MERCURY (HIGH DENSITY)

FLOW LAYERS (LAMINAR FLOW)

SURFACE TENSION

Surface behaves like a stretched membrane.

CAPILLARY RISE

Rise occurs when adhesive force > cohesive force.

$$h = \frac{2\sigma\cos\theta}{\rho g r}$$

VISCOSITY (SHEAR FLOW)

$$\tau = \mu \frac{du}{dy}$$

8 SURFACE TENSION (σ)

Definition: Force per unit length acting tangentially on the surface of a liquid.

SI Units: N/m

Importance: Affects droplets, bubbles and capillary action.

Example: Surface tension of water at 20°C $\approx$ 0.0728 N/m.

Applications: Droplet formation, inkjet printing, detergents, heat exchangers.

9 CAPILLARITY

Definition: Rise or fall of a liquid in a small tube due to surface tension and adhesion.

Importance: Important in small diameter tubes and porous media.

Example: Water rises in a thin glass tube.

Applications: Wick in lamps, soil moisture movement, microfluidics, heat pipes.

10 VAPOUR PRESSURE (P_v)

Definition: Pressure exerted by vapour in equilibrium with its liquid at a given temperature.

SI Units: Pa

Importance: Indicates tendency of liquid to vaporize.

Example: Vapour pressure of water at 20°C $\approx$ 2.339 kPa.

Applications: Boiler design, cavitation prediction, evaporation processes.

9.7.2.9 Speed of sound in a liquid

Let us take a moment to calculate the speed of sound in a liquid. We have proved in the our study of the longitudinal sound waves of the Mathematical Music section that:

$$\frac{\mathrm{d}P}{\mathrm{d}\rho}=-\gamma\frac{P}{\rho_0} \tag{9.7.601}$$

where, for recall, γ is the "Laplace coefficient", also named "adiabatic coefficient" defined by:

$$\gamma=\frac{C_P}{C_V} \tag{9.7.602}$$

and we had proved that the speed of the sound wave was given by:

$$v=\sqrt{\frac{\gamma}{\rho_0}} \tag{9.7.603}$$

Combining it comes:

$$v=\sqrt{\frac{1}{-\dfrac{\mathrm{d}\rho}{\mathrm{d}P}}}=\sqrt{\frac{1}{-\dfrac{\mathrm{d}\left(\dfrac{m}{V}\right)}{\mathrm{d}P}}}=\sqrt{\frac{1}{-\dfrac{-\dfrac{m}{V^2}\mathrm{d}V}{\mathrm{d}P}}}=\sqrt{\frac{1}{\dfrac{m}{V}\dfrac{\dfrac{\Delta V}{V}}{\Delta P}}}=\sqrt{\frac{1}{\rho\dfrac{\dfrac{\Delta V}{V}}{\Delta P}}}=\sqrt{\frac{B}{\rho}} \tag{9.7.604}$$

The fraction:

$$\boxed{B=-\frac{\Delta P}{\Delta V}V} \tag{9.7.605}$$

that is to say the ratio between a variation in pressure and the relative variation in volume which it entails is named the "volumetric modulus of elasticity". Notice that the sign $-$ is required for B to be positive: when the pressure increases, the volume decreases!

We have for example for water:

$$v=\sqrt{\frac{1}{\dfrac{\rho}{B}}}\cong\sqrt{\frac{1}{\dfrac{1000}{2\cdot 10^9}}}=1,414\,[\mathrm{m}\cdot\mathrm{s}^{-1}] \tag{9.7.606}$$

The measured value being in real life in standard condition of temperature and pressure: $1,441\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$. It may seem surprising that the velocity of sound in a liquid, which is much more difficult to compress than a gas is only 5 times greater than in a gas. The reason is that the density of a liquid is about a thousand times higher than that of a gas. In both, the two properties partially compensate.

9.7.2.10 Summary of fluid dynamics laws

Here is a summary of the gas laws proven so far we have seen so far on request of a few readers (for reminder these laws assume ideal fluid behavior, i.e. particles have no volume and exert no intermolecular forces on one another and temperatures are always in Kelvin):

- **Continuity Law:** Governs that mass entering a system must equal mass leaving the system plus any accumulation. For an incompressible fluid, the volumetric flow rate remains constant across variable cross-sections

$$\frac{\partial\rho}{\partial t}+\nabla\circ(\rho\vec{u})=0 \tag{9.7.607}$$

- **Navier-Stokes Law:** Describes how the velocity field of a viscous fluid changes under the influence of internal forces (pressure and viscosity) and external forces (gravity)

$$\rho_{\mathrm{d}}\vec{v}=-\vec{\nabla}p+\frac{4}{3}\left(\mu_d+\mu'_d\right)\vec{\nabla}(\vec{\nabla}\circ\vec{v})-\mu_d\vec{\nabla}\times(\vec{\nabla}\times\vec{v})+\rho\vec{f} \tag{9.7.608}$$

- **Bernoulli's Law:** States that for an inviscid, incompressible, and irrotational flow along a streamline, an increase in fluid speed occurs simultaneously with a decrease in static pressure or potential gravitational energy

$$p+\frac{1}{2}\rho v^2+\rho gh=c^{te} \tag{9.7.609}$$

- **Archimedes' Law:** Any body completely or partially submerged in a fluid at rest is acted upon by an upward, or buoyant, force proportional to the weight of the fluid displaced by the body and by the local acceleration of gravity:

$$F_B=\rho gV_{\text{displaced}} \tag{9.7.610}$$

- **Pascal's Law:** A pressure change applied to an enclosed, incompressible fluid at rest is transmitted undiminished throughout the fluid and to the walls of its container

$$\Delta p=\rho g\Delta h \tag{9.7.611}$$

- **Newton's viscosity Law:** Dictates that the shear stress between adjacent fluid layers is directly proportional to the negative velocity gradient perpendicular to the direction of flow (fluids adhering to this are classified as "Newtonian")

$$\tau=\mu\frac{\partial u}{\partial y} \tag{9.7.612}$$

- **Hagen-Poiseuille Law:** Calculates the pressure drop in an incompressible, Newtonian fluid undergoing laminar flow through a long cylindrical pipe of constant cross-section

$$J=\frac{\pi R^4}{8\mu_d}\frac{\Delta P}{l} \tag{9.7.613}$$

- **Stokes' Drag Law:** Gives the frictional force-also known as drag force-exerted on spherical objects moving at very ow Reynolds numbers (creeping flow) through a viscous fluid

$$\Delta p = \frac{8\mu LQ}{\pi R^4} \tag{9.7.614}$$

- **Torricelli's Law:** An application of Bernoulli's principle that determines the efflux velocity of a liquid leaving an open orifice under the sole action of gravity

$$v = \sqrt{2gh} \tag{9.7.615}$$

- **Isoperimetric Law:** Any fluid under its own mass will tend to a collapse into a sphere to minimize its energy state (see the section of Geometry for the detailed proof)

$$4\pi\mathcal{A}(\text{Int}(\gamma)) \leq \mathcal{L}(\gamma)^2 \tag{9.7.616}$$

- **Levelling Law:** A stationary compressible inviscid fluids in a gravitational potential and having an isobaric surface will always be at level (see definition of "level" at page 5260)

$$\vec{0} = \vec{\nabla}\rho \times (\vec{\nabla}\varphi) \Leftrightarrow \nabla\rho \parallel \vec{\nabla}\varphi \tag{9.7.617}$$

The reader must keep in mind there are plenty of other gas laws but that we didn't prove so fare in this textbook!

9.7.3 Gas

The solids have a well defined shape and are difficult to compress. Liquids can flow freely and their flow is limited by self-formed surfaces. The gases dilate freely to occupy the volume of the receptacle containing them, and have a density about a thousand times lower than that of liquids and solids. They conduct heat and electricity only a little, unless we ionize them (forming then plasma). The molecules of a neutral gas move along rectilinear trajectories which change direction with each collision with another molecule. Unlike solids and liquids, interactions between molecules remain weak. The macroscopic properties of a gas are thus directly deduced from the properties of the molecules that compose it (or atoms in the case of a monoatomic gas).

Definition (#9.7.475): A "gas" is a diluted fluid, in the sense that its state of matter characterized by the fact that it doesn't have a fixed shape or volume (a gas will expand to fill the entire volume of its container), it can be compressed (meaning their volume can be decreased under pressure), the molecules in the gas can move freely and are widely spaced compared to liquids and solids, the behavior of the gas is significantly influenced by changes in temperature and pressure.

9.7.3.1 Types of Gas

In gas theory (we often speak of "kinetic theory of gases") we always consider two types of neutral gases:

9.7.3.1.1 Perfect Gas

The "perfect gas" is a model in which we neglect the molecular interactions of the gas, with the exception of collisions, and whose own volume is negligible relatively to the volume of the container. We deduce from these considerations that the behaviour of a real gas can be approached by a perfect gas if the volume it occupies is sufficiently large, which will occur at low pressure and at high temperature. In practice, the perfect gas model gives satisfactory results for many conventional gases taken at atmospheric pressure and at ambient temperature (nitrogen, oxygen, steam, etc.).

When a gas is at low pressure, the interactions between its molecules are weak. Thus, the properties of a real gas at low pressure approximate those of a perfect gas. We can then describe the behaviour of the gas by the "equation of state of perfect gases" that we will prove in detail further below during our study of the virial theorem (see section Continuum Mechanics page 3897):

$$\boxed{PV = nRT} \tag{9.7.618}$$

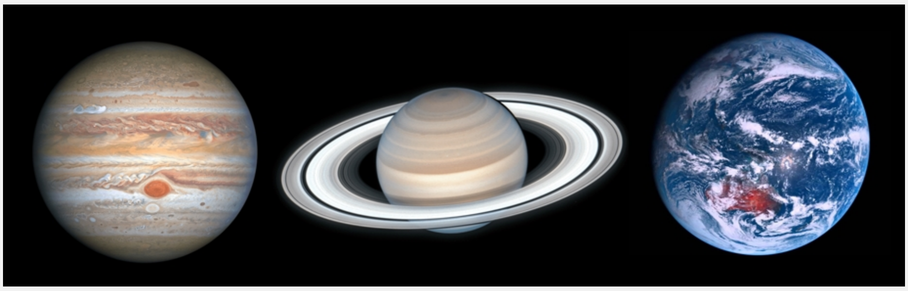
With n the number of moles of gas, P the gas pressure, V the volume occupied by the n moles and T the absolute temperature of the gas. The constant R being the "constant of the perfect gases":

$$R = 8.3144598(48)\,[\mathrm{J}\cdot\mathrm{mol}^{-1}\cdot\mathrm{K}^{-1}] \tag{9.7.619}$$

Remark

The pressure of a gas is defined as the force the gas would exert upon a surface or container. However, there is no need of a container for pressure to exist! For instance, the air you are breathing right now (unless you're in an airplane or submarine) has pressure due to the column of atmosphere above you that exist due to Earth's gravity. Stars are balls of gas (plasma, actually) that are also pressurized by gravity; no containers to be seen!

We can have a vacuum environment next to a pressurized system without a solid barrier between them due to gravity which is scientifically proven by multiple independent empirical observations:



On Earth itself we also don't need a closed container to keep a gas that has a molar mass much greater than air, like sulfur hexafluoride (SF_6) that has a molar mass of $146.06\,[\text{g}\cdot\text{mol}^{-1}]$ considerably higher than the density of oxygen O_2 with its $31.998\,[\text{g}\cdot\text{mol}^{-1}]$ or even CO_2 with its $44.009\,[\text{g}\cdot\text{mol}^{-1}]$. It is therefore allowing experiments like the one visible in the photo below, where soap bubble are suspended over a tank (container without top):

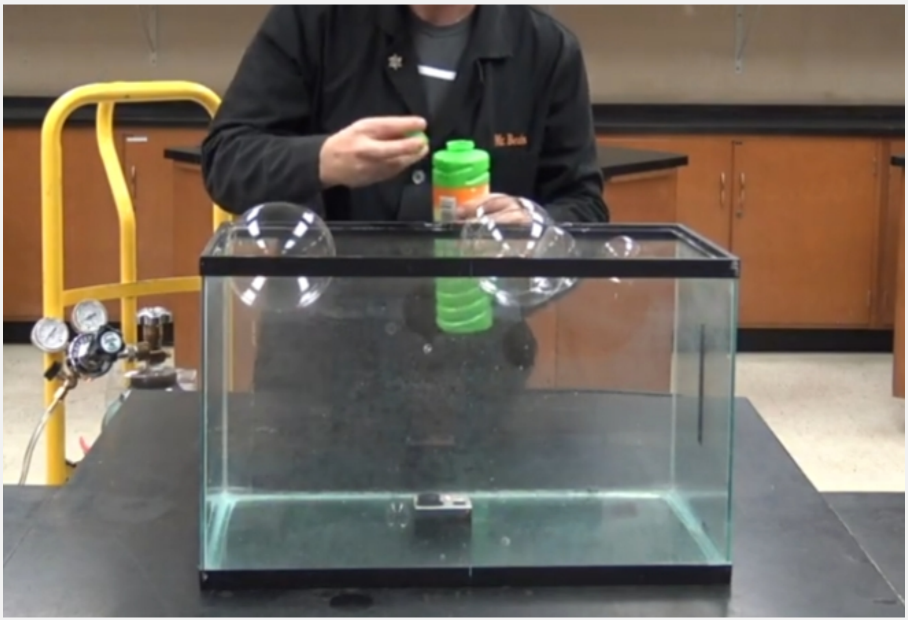


Figure 9.262: Example of a gas (SF_6) contained in a container without top (author: Craig Beals, source: `https://www.youtube.com/watch?v=KHmNiOsTYfA`)

This equation shows trivially that:

- At constant temperature T ("isothermal" system), the volume of a fixed quantity of an ideal gas is inversely proportional to its pressure (that exclude the range of temperatures and pressures where the gas behaves like a liquid or like a solide obviously). This is the "Boyle-Mariotte's law":

$$\boxed{V=\frac{c^{te}}{P}} \tag{9.7.620}$$

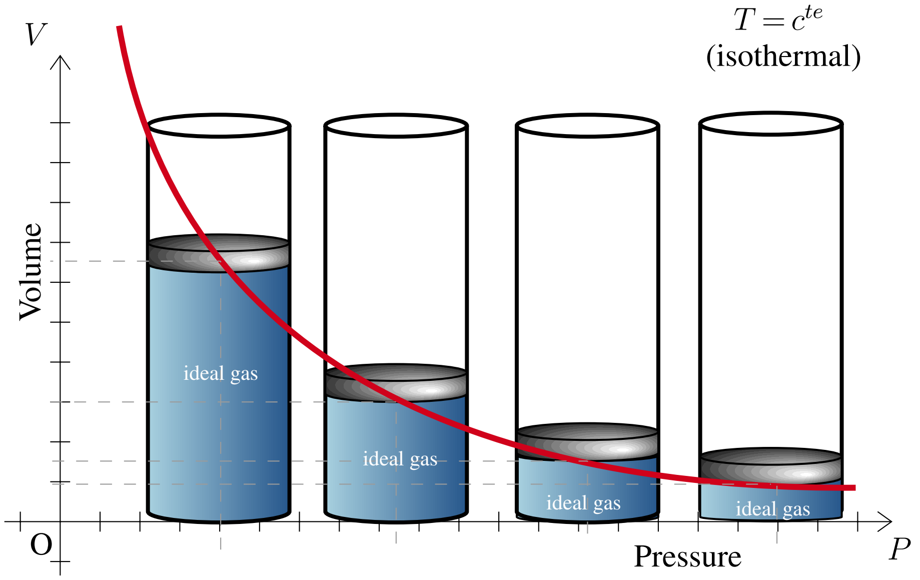

Figure 9.263: Boyle-Mariotte's law illustration

From the Boyle-Mariotte's law, we deduce immediately that at constant temperature (i.e. during an isothermal transformation):

$$\boxed{P_1V_1=P_2V_2\Leftrightarrow\frac{P_1}{P_2}=\frac{V_2}{V_1}} \tag{9.7.621}$$

A real PV diagram taken from an old handbook for Oxygen is given below for people interested (the reader can notice that when the temperature is too low... the gas doesn't behave like an ideal gas anymore and at some very low temperature it isn't a gas at all anymore!):

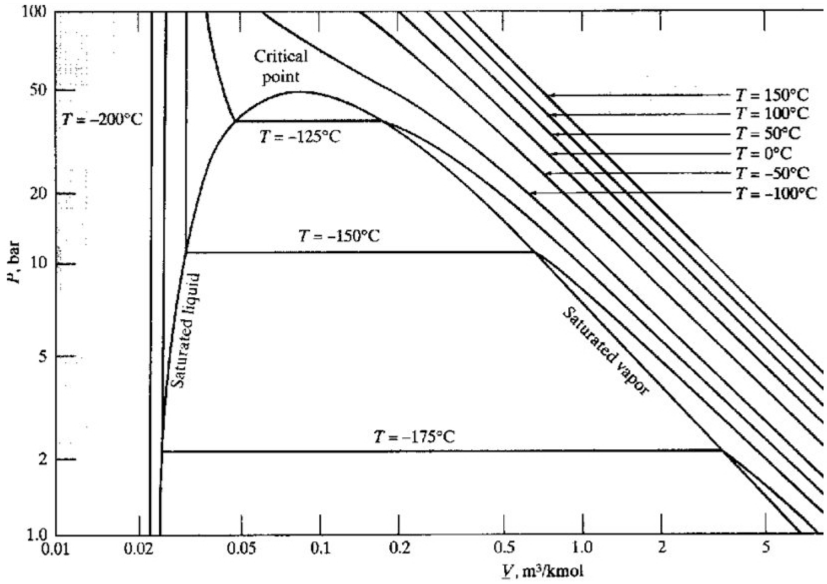

Figure 9.264: PV **diagram for oxygen**

- At constant pressure P ("isobaric" system), the volume of a fixed quantity of ideal gas is proportional to the absolute temperature (therefore and again... this doesn't include the ranges of pressure and temperatures where the gas isn't a gas anymore!). This is the "Charles' law" (in the case of perfect gases ...):

$$\boxed{V = c^{te}T} \tag{9.7.622}$$

Obviously the Kelvin scale must be used because zero on the Kelvin scale corresponds to a complete stop of molecular motion!

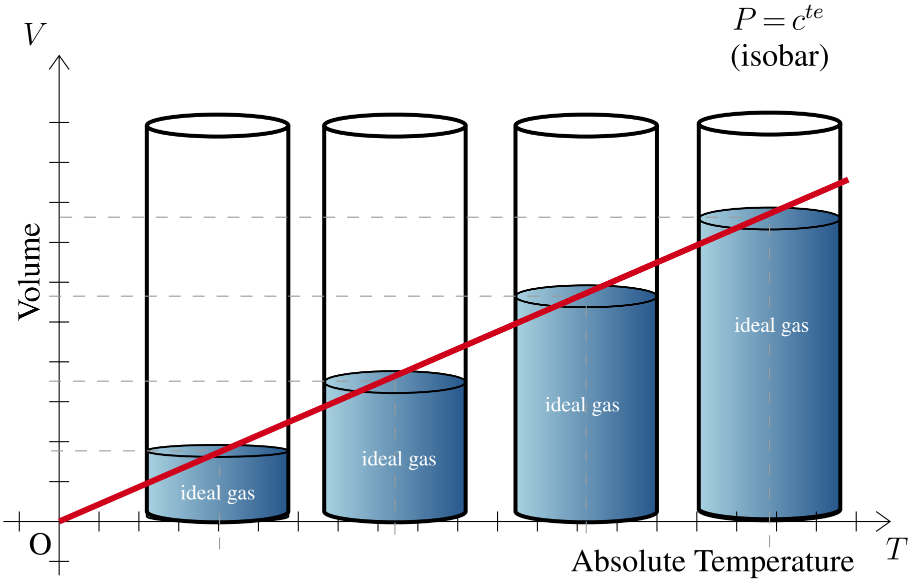

Figure 9.265: **Charles' law illustration**

The experiment is performed at a constant atmospheric pressure. The experiment proceeds by placing an empty flask in a boiling water bath. As the temperature increases, the air inside the flask expands. Afterwards, the gas is cooled in a water bath by maintaining the amount of the air in the flask constant. By measuring/determining the initial and final temperature and volume, we verify Charles' law.

Notice that the line goes exactly toward the origin, meaning that as the absolute temperature of the gas approaches zero, its volume approaches zero. However, when a gas is brought to extremely cold temperatures, its molecules would eventually condense into the liquid state before reaching absolute zero. The temperature at which this change into the liquid state occurs varies for different gases.

From the Charles's law, we deduce immediately that at constant pressure (i.e. during an isobaric transformation):

$$\boxed{\frac{V_1}{T_1}=\frac{V_2}{T_2}\Leftrightarrow V_1T_2=V_2T_1} \tag{9.7.623}$$

It is this relation which is often used in the labs of small classes to show that with an extrapolation of the measured line, the volume theoretically becomes zero at a temperature of about -273.15 [°C]. Notice by the way seriously from a certain temperature, it is necessary to use quantum models and moreover this relation is valid only for the gases (thus, when the water vapour becomes liquid ... it is no longer valid).

Let also recall that we have proved a more elaborate expression of the Gay-Lussac's law in the section of Thermodynamics by making use of equations of state and thermoelastic coefficients ...:

$$\Delta V=\alpha_V V_0\Delta T \tag{9.7.624}$$

This show us that the Gay-Lussac's law then no longer really have the status of "law" but rather that of a "relation" as in can be proved! We have also proved in the section of Thermodynamics that this law is only approached to the high pressures for the gases since they must be considered as incompressible like liquids to obtain the relation in question.

- At constant volume V ("isochore" system), the pressure of a fixed quantity of gas is proportional to its absolute temperature. This is the "Gay-Lussac's law":

$$\boxed{P=c^{te}T} \tag{9.7.625}$$

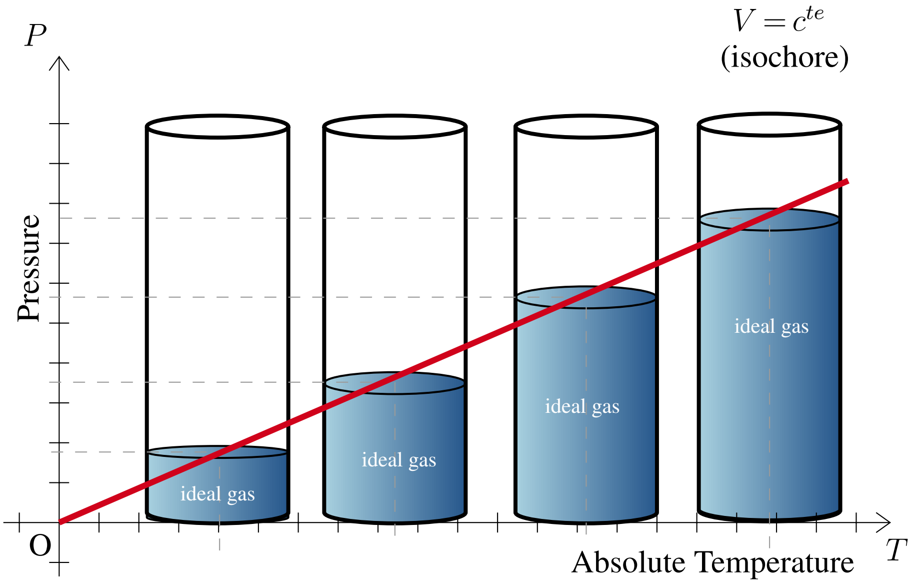

Figure 9.266: **Gay-Lussac's law illustration**

From the Gay-Lussac's law, we deduce immediately that at constant volume (i.e. during an isochoric transformation):

$$\boxed{\frac{P_1}{T_1}=\frac{P_2}{T_2}\Leftrightarrow P_1T_2=P_2T_1} \tag{9.7.626}$$

The reader may have noticed that the underling idea of Gay-Lussac's law is very similar to Charles's law. Indeed, the only difference being the type of container. Whereas the container in a Charles's law experiment is flexible, it is rigid in a Gay-Lussac's law experiment!

Subsequently, Amedeo Avogadro, to whom we owe the word of "molecule" affirms the molecular concept of gases and concludes that equal volumes of different gases, taken under the same conditions of temperature and pressure, contain the same number of molecules (this observation now follows automatically from the equation of perfect gases which will be proved further below in details). This property was named the "Avogadro and Ampere law" and is often illustrated as follow:

$$\boxed{V=nc^{te}} \tag{9.7.627}$$

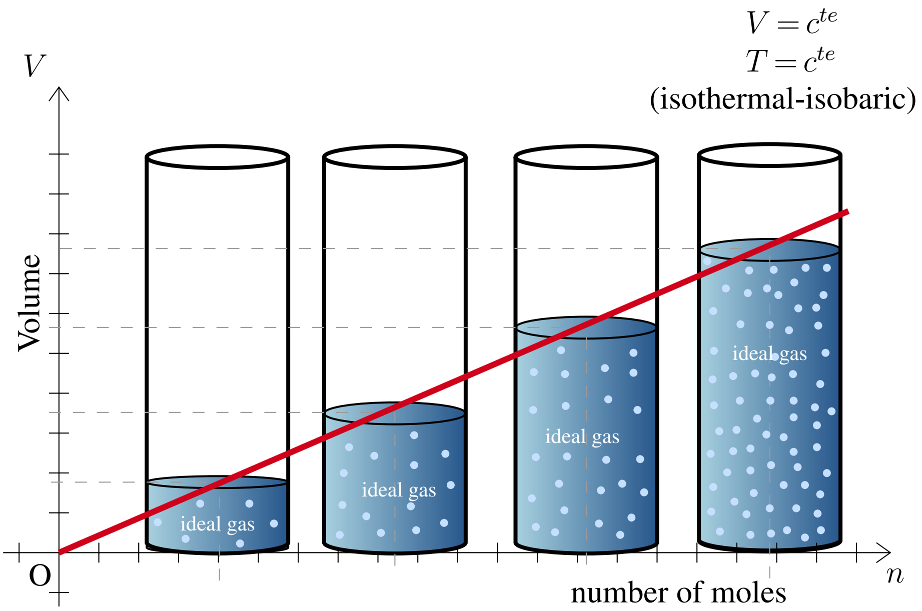

Figure 9.267: **Avogadro's law illustration**

In other words, Avogadro's Law states that the volume of a gas is directly proportional to the number of moles (or number of particles) of gas when the temperature and pressure are held constant.

From the Avogadro's law, we deduce immediately that at constant temperature and constant volume we then have:

$$\boxed{\frac{V_1}{n_1} = \frac{V_2}{n_2} \Leftrightarrow V_1 n_2 = V_2 n_1} \qquad (9.7.628)$$

If the container holding the gas is rigid rather than flexible, pressure can be substituted for volume in Avogadro's Law. Adding gas to a rigid container makes the pressure increase.

✍**Example:**

The air in a diving cylinder is initially at the pressure P_i in a volume V_i corresponding to that of the diving cylinder that we assume to be $0.015\,[\mathrm{m}^3 \cdot \mathrm{s}^{-1}]$. A diver never breathes air directly into the bottle because of the pressure that is about 200 times higher than the atmospheric pressure $20.02 \cdot 10^7$ [Pa] would blow his lungs. A valve makes it possible to adjust the pressure of the air sent to the plunger so that it is equal to the ambient pressure P_t of the water depth. It is interesting to calculate the time t that the diver can stay underwater at a depth of 10 meters if it is assumed to consume 0.03 cubic meters per minute.

To answer this question we must therefore first know the pressure P_f at 10 meters depth. For this we will use the Hydrostatic theorem proved during our study of fluids:

$$P_f = P_{\text{atm}} + \rho_{\text{water}} g h = 1.01 \cdot 10^5 + 1025 \cdot 9.81 \cdot 10 \cong 2.01 \cdot 10^5 \text{ [Pa]} \qquad (9.7.629)$$

Afterwards the volume in the bottle should be set to the above pressure volume using the

Boyle-Mariotte's law:

$$P_iV_i = P_fV_f \tag{9.7.630}$$

We then have as equivalent volume:

$$V_f = \frac{P_iV_i}{P_f} \cong \frac{2.02 \cdot 10^7 \cdot 0.015}{2.01 \cdot 10^5} = \frac{2.02 \cdot 10^7 \cdot 0.015}{2.01 \cdot 10^5} = 1.507\,[\text{m}^3] \tag{9.7.631}$$

But the trap is that the usable volume is smaller because it still requires air to push the remaining air. We must then subtract the two volumes:

$$V_{\text{usable}} = V_f - V_i = 1.507 - 0.015 = 1.492\,[\text{m}^3] \tag{9.7.632}$$

And dividing by a standard volume consumption rate C we have at the end:

$$t = \frac{V_f - V_i}{C} = \frac{\dfrac{P_iV_i}{P_f} - V_i}{C} = \frac{\dfrac{P_iV_i}{P_{\text{atm}} + \rho_{\text{water}}gh} - V_i}{C} = \frac{1.492\,[\text{m}^3]}{0.03\,\left[\text{m}^3 \cdot \text{min}^{-1}\right]} = 49.7\,[\text{min}] \tag{9.7.633}$$

So to summarize so far:

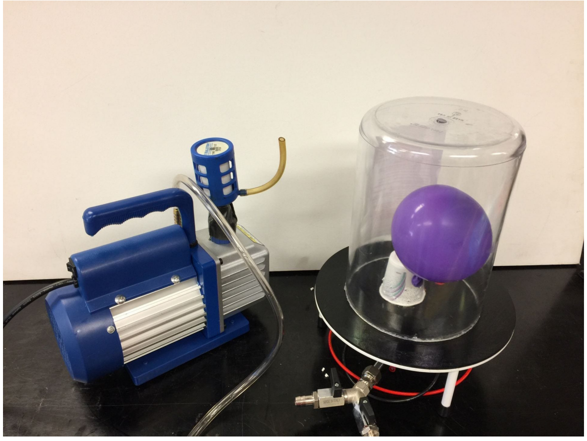
Gas Law	**Formula**
Boyle's law	$P_1V_1 = P_2V_2$
Charles's law	$\frac{V_1}{T_1} = \frac{V_2}{T_2}$
Gay-Lussac's law	$\frac{P_1}{T_1} = \frac{P_2}{T_2}$
Avogadro's law	$\frac{V_1}{n_1} = \frac{V_2}{n_2}$
Combined law	$\frac{PV_1}{T_1} = \frac{P_2V_2}{T_2}$
Ideal gas law	$PV = nRT$

Table 9.36: **Summary of ideal gas laws**

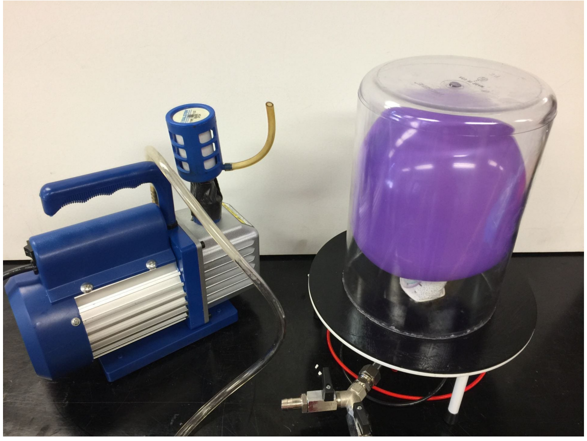
Caution! Collisions between gas particles or collisions with the walls the container are perfectly elastic! None of the energy of gas particles is lost when it collides with another particle or with the walls of the container. More generally, they do lose or gain energy when they crash into walls. If the walls are the same temperature as the gas they will on average gain as much as the lose. If the walls are colder they will lose more than they gain heating the walls. If the wall is hotter than the gas they will gain more than they lose heating the gas.

Let us illustrate now the effects of a change in atmospheric pressure, especially the expansion in a Vacuum as it often misunderstood by some children (and even adults...)!

Below we can see a latex balloon that rests on a stand in a bell-jar. The balloon expands when the air is removed from the jar by a vacuum pump:



(a) Latex ballon filled with air in the in the bell-jar filled with air

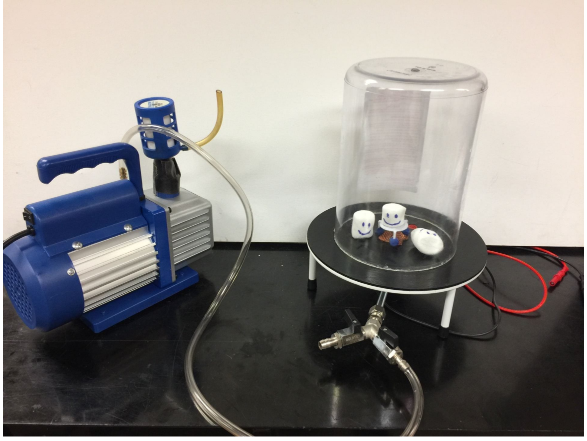


(b) Latex balloon filled with air in pseudo-vacuum bell-jar

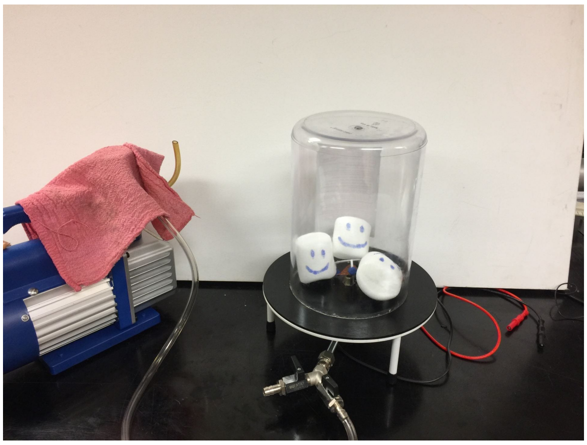
The latex balloon will not float in air, since the latex balloon is only filled with air, and hence, not light enough by Archimedes' Principle to float. In this case, the latex balloon rests on a stand that is inside of the bell-jar. The latex balloon is tied off, which makes the latex balloon behave as a closed system, and exerts a constant pressure from the inside of the latex balloon in the outward, radial direction.

When the latex balloon is in the bell-jar full of air, the balloon is at equilibrium, since the pressure exerted by the air inside of the balloon is equal to the pressure of the atmosphere that is acting on the outside of the balloon. When the atmosphere (air) inside of the bell-jar is pumped out, the system is no longer in equilibrium, since the atmospheric pressure in the bell-jar is decreasing, while the pressure inside of the latex balloon remains constant. The pressure inside of the latex balloon is greater than the atmospheric pressure, and the latex balloon with start to expand, until it reaches equilibrium.

Now the same experiment with an object having a stronger molecular structure:



(a) Marshmallows in the bell-jar, filled with air



(b) Marshmallows in pseudo-vacuum bell-jar

Marshmallows have little pockets of air that are trapped inside of them. When the marshmallows is in the bell-jar full of air, the pressure exerted by the air pockets inside of the marshmallows are in equilibrium with the atmospheric pressure inside of the bell-jar. As the atmospheric pressure in the bell-jar decreases due to air being sucked out by the vacuum pump, the system is no longer in an equilibrium state, and the pressure coming from the air pockets inside of the marshmallow is greater than the decreasing atmospheric pressure. The pressure of the air pockets cause the marshmallows to expand less significantly than the balloon.

Now let us come back to the equation of state of perfect gases:

$$PV = nRT \tag{9.7.634}$$

9.7.3.1.2 Real Gas

The perfect gas equation is obviously approximate. For example, a perfect gas could neither liquefy nor solidify, regardless of the cooling and compression to which it is subjected. Real gases, especially under conditions of pressure and temperature close to the transition to the liquid state, can present considerable deviations with the law of perfect gases!

It must therefore be adapted to real cases. For this we use the Van der Waals equation of state which is particularly useful and well known. It can be obtained qualitatively once the perfect gas equation is demonstrated and is then given by (see below how we prove it):

$$\boxed{\left(P+\frac{a}{V^2}\right)(V-b)=RT} \tag{9.7.635}$$

for one mole, a and b being adaptable parameters determined by experimental measurements carried out on the concerned gas (a is a measure of the average attraction between particles, b the volume excluded by a mole of particles). These are parameters that vary from one gas to another.

The Van der Waals equation can also be interpreted at the microscopic level. Molecules interact with each other. This interaction is strongly repulsive for the molecules close to one another, becomes slightly attractive for a mean distance and disappears when the distance is important. At high pressure, the perfect gas law must be rectified to take into account attractive or repulsive forces.

9.7.3.2 Virial Theorem

We will here discuss a study of perfect gases via a particular method. It makes it possible to obtain an interesting result and particularly for astrophysics (see section Astrophysics page 5539). The virial theorem[40] also makes it possible to obtain other very interesting results but which pedagogically are somewhat difficult to access. The reader who would be interested in this second part of the results can directly go back a little further where the concepts of pressure and kinetic temperature are treated.

By definition, the "virial expression $V_{\text{ir.}}$" of a material point is the scalar:

$$\boxed{V_{\text{ir.}} = \vec{F}\circ\vec{r}} \tag{9.7.636}$$

---

[40] The word *virial* derives from *vis*, the Latin word for *force* or *energy*, and was given its technical definition by Rudolf Clausius in 1870.

By definition, the "virial" of a system composed of N material points is:

$$V_{\text{ir.}}=\sum_{i=1}^{N}\vec{F}_i\circ\vec{r}_i \tag{9.7.637}$$

Subjected to a central force, the virial is written (by the properties of the scalar product):

$$V_{\text{ir.}}=\sum_{i=1}^{N}F_i r_i \tag{9.7.638}$$

The "virial theorem" states: For a system in equilibrium (!), the internal energy is equal to the opposite of its total half-virial when all the particles are located with respect to its center of mass.

Proof 9.10.6. Given the differentiation (see section Differential and Integral Calculus page 1464):

$$\mathrm{d}_t r_i^2=2r_i\mathrm{d}_t r_i \tag{9.7.639}$$

Its second derivative:

$$\mathrm{d}_t^2 r_i^2=\mathrm{d}_t(2r_i\mathrm{d}_t ri)=2\mathrm{d}_t r_i\mathrm{d}_t r_i+2r_i\mathrm{d}_t^2 r_i=2(\mathrm{d}_t r_i)^2+2r_i\mathrm{d}_t^2 r_i \tag{9.7.640}$$

Multiplying by m_i and summing on i:

$$\mathrm{d}_t^2\sum_{i=1}^{N}m_i r_i^2=2\sum_{i=1}^{N}\left[m_i(\mathrm{d}_t r_i)^2+\vec{r}_i m_i\mathrm{d}_t^2 r_i\right] \tag{9.7.641}$$

But:

$$m_i\mathrm{d}_r^2 r_i=F_i \tag{9.7.642}$$

and:

$$\mathrm{d}_t r_i=v\Rightarrow(\mathrm{d}_t r_i)^2=v_i^2 \tag{9.7.643}$$

Therefore:

$$\mathrm{d}_t^2\sum_{i=1}^{N}m_i r_i^2=2\left[\sum_{i=1}^{N}m_i v_i^2+\sum_{i=1}^{N}r_i F_i\right] \tag{9.7.644}$$

This last expression is valid whatever the position of the adopted coordinate system. However, it is interesting to place its origin at the center of mass (centroid) of the system because we are no longer dependent on its movement.

If the system is in equilibrium, the macroscopic quantities which characterize it are not dependent on time. We then conclude that the sum of any quantity attached to any material point of the system is in fact a quantity of that system.

Thus, $\sum m_i r_i$ is a macroscopic quantity independent of time. That implies that:

$$\sum m_i v_i^2+\sum r_i F_i=0 \tag{9.7.645}$$

What is written again (we multiply by $1/2$ on both sides):

$$\frac{1}{2}\sum m_i v_i^2 = -\frac{1}{2}\sum r_i F_i \qquad (9.7.646)$$

So we have finally:

$$E_c = \frac{1}{2}V_{\text{ir.}} \qquad (9.7.647)$$

This expression of kinetic energy is known as "virial theorem" and the right-hand side is therefore named the "virial of the system".

■ Q.E.D.

We write that:

$$E_c = N\langle E_c\rangle \qquad (9.7.648)$$

where E_c is the total kinetic energy associated with all the material points of the system. We name it the "internal energy of the system" and thermodynamicists often denote it with the letter U as we know it...! The term $\langle E_c\rangle$ is the energy of any material point in the system.

It is possible to fall back on the expression of the virial from a system of particles (cloud in accretion). Strictly speaking, equilibrium does not exist in such a case. Nevertheless, we can assume that if the gravitational contraction is sufficiently slow then its different phases can be considered as a succession of equilibrium states (typical thermodynamic approach that we already know).

In the case of a central force and derived from a potential, we can write (see section Classical Mechanics page 3351):

$$F = -\frac{\partial E_p}{\partial r} \qquad (9.7.649)$$

and therefore:

$$Fr = -r\frac{\partial E_p}{\partial r} \qquad (9.7.650)$$

If the potential energy is of the form k/r (which is the case for the electrical and gravitational potential) then it comes:

$$Fr = E_p \qquad (9.7.651)$$

and it remains:

$$\boxed{E_c = -\frac{1}{2}E_p} \qquad (9.7.652)$$

sometimes denoted and rewritten (especially in Astrophysics):

$$2T + U = 0 \qquad (9.7.653)$$

In summary, the virial theorem gives us a relation between total kinetic and potential energies. To be valid, the mobile must describe a trajectory around the center of central force and remain indefinitely in a finite volume (bound state). This type of reasoning can be applied to a very large number of phenomena, from the structure of certain galaxies to the release of energy in nuclear explosions through the study of the Sun (actually a G2V-type star, aka yellow dwarf) and the behaviour of real gases. This is the first result we were interested in.

Remark

Astrophysicists use (veeery roughly and stupidly as the assumptions are not satisfied!) the relation:

$$2T+U=0 \tag{9.7.654}$$

for galaxy clusters.... with:

$$T=\frac{1}{2}\sum_i m_i v_i^2 \cong \frac{1}{2}M_D v^2 \tag{9.7.655}$$

where M_D is the cluster mass and:

$$U=\sum_{i,j}-\frac{1}{2}\frac{Gm_i m_j}{|\vec{r}_i-\vec{r}_j|}\cong -\frac{1}{2}\frac{M_D^2 G}{R} \tag{9.7.656}$$

where R is the estimated galaxy cluster radius. Therefore:

$$\boxed{M_D \cong \frac{2Rv^2}{G}} \tag{9.7.657}$$

and according to the bad astrophysicists that do this huge approximation, the observed M_D is not compliant with the calculated one, so there must be something missing that we can't see and that they name the "dark matter"... It should be interesting to do the calculations without so huge approximations and with a model that have assumptions that are compatible with galaxies...

Since June 12025 (holocene calendar) it is known thanks to FRB (Fast Radio Bursts) that approximately 76% of the Universe's baryonic matter lies in the IGM (InterGalactic Medium). About 15% resides in galaxy halos, and a small fraction is burrowed in stars or amid cold galactic galactic gas ([109]).

In a gaseous system, the potential energy can be written as the sum of the energy of the forces acting from the outside and those which are internal even to the gas. Such as:

$$E_p=\sum_{i=1}^N \vec{F}_i\circ\vec{r}_i=\sum_{i=1}^N \vec{F}_{i,\text{int.}}+\sum_{i=1}^N \vec{F}_{i,\text{ext.}} \tag{9.7.658}$$

But the internal forces can be written as:

$$\vec{F}_{i,\text{int.}}=\sum \vec{F}_{ij} \tag{9.7.659}$$

It is not necessary in this sum to take the force exerted by each of the particles upon itself. Such as:

$$\vec{F}_{i,\text{int.}}=\sum_{i\neq j} \vec{F}_{ij} \tag{9.7.660}$$

What give us:

$$E_p=\sum_{i=1}^N \vec{F}_i\circ\vec{r}_i=\sum_{j\neq i} \vec{F}_{ij}\circ\vec{r}_i+\sum_{i=1}^N \vec{F}_{i,\text{ext.}} \tag{9.7.661}$$

In the double sum, we can group the terms two by two and use the principle of action-reaction such as:

$$\vec{F}_{ij}=-\vec{F}_{ij} \tag{9.7.662}$$

To get by definition:

$$\vec{F}_{ij}\circ r_i+\vec{F}_{ji}\circ\vec{r}_j=\vec{F}_{ij}(\vec{r}_i-\vec{r}_j):=\vec{F}_{ij}\circ\vec{r}_{ij} \tag{9.7.663}$$

What ultimately gives us:

$$E_p=\sum_{i\neq j}\vec{F}_{ij}\circ\vec{r}_{ij}+\sum_{i=1}^{N}\vec{F}_{i,\text{ext.}}\circ\vec{r}_i \tag{9.7.664}$$

And:

$$E_c=\frac{1}{2}E_p=\frac{1}{2}\left(\sum_{i\neq j}\vec{F}_{ij}\circ\vec{r}_{ij}+\sum_{i=1}^{N}\vec{F}_{i,\text{ext.}}\circ\vec{r}_i\right) \tag{9.7.665}$$

The first term on the right involves the internal forces (interactions) between the (pairs of) particles and the second term on the right involves external forces.

Let us consider now a gas contained in a tank. Its molecules are subject to external forces only when they hit a wall and we imagine that on average this force is perpendicular to the wall (elastic shocks).

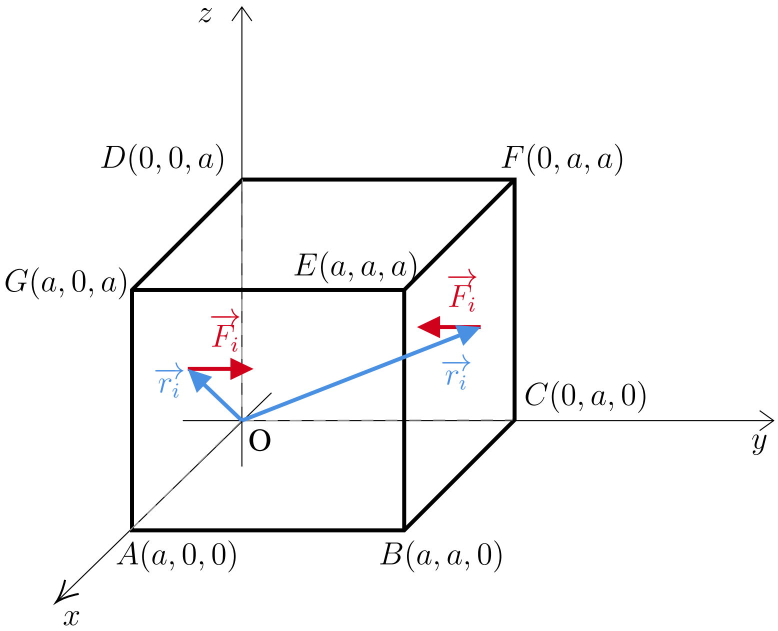


Figure 9.270: **Gas contained in a tank**

For all the faces contained in the planes defined by the axes, we always have:

$$\vec{r}_i\circ\vec{F}_i=0 \tag{9.7.666}$$

Since on average $\vec{F}_i$ is always perpendicular to $\vec{r}_i$.

For the other faces ($BCFE$ for example) we have:

$$\vec{F}_i = -F_i\vec{u}_y \qquad (9.7.667)$$

and thus:

$$\vec{r}_i \circ \vec{F}_i = r_i F_i \cos(\alpha) = -aF_i \qquad (9.7.668)$$

where we denote by a the coordinate according to Oy of the end of $\vec{r}_i$ (not to be confused with acceleration!). Therefore for each face:

$$\sum_{i=1}^{N} \vec{F}_i \circ \vec{r}_i = -a\sum_{i=1}^{N} F_i = -aF = -Pa^3 = -PV \qquad (9.7.669)$$

Indeed because the internal pressure of the system on the walls is defined by:

$$P = \frac{F}{S} = \frac{F}{a^2} \qquad (9.7.670)$$

By the virial theorem, by adding the non-zero contributions of the faces $BCFE$, $DEFG$ and $ABED$, it comes:

$$E_c = \frac{3}{2}PV - \frac{1}{2}\sum_{j\neq 1} \vec{F}_{ij} \circ \vec{r}_{ij} \qquad (9.7.671)$$

If the average kinetic energy of a molecule is:

$$E_c = \frac{1}{2}mv^2 = \frac{3}{2}kT \qquad (9.7.672)$$

The total mean kinetic energy for N molecules is then (we will return to this relation later but with another approach):

$$\boxed{E_c = \frac{N}{2}mv^2 = \frac{3}{2}kNT = \frac{3}{2}\frac{R}{N_\text{A}}NT} \qquad (9.7.673)$$

that thermodynamicists often write:

$$U = n\frac{\text{df}}{2}RT \qquad (9.7.674)$$

where U is as we know the internal energy of the gas and df the number of degrees of freedom of the constituents.

The prior relation, named the "equipartition theorem of energy" (as it assumes that the total kinetic energy is equally distributed by each degree of freedom) is important because it allows:

1. A microscopic interpretation of temperature T and to determine the internal energy of a monoatomic perfect gas (and by extension of other gases with other degrees of freedom).
2. To notice that the temperature system in Celsius is not adapted to the physical reality. Indeed, in the system using the Celsius, at 0 [°C] everything should be immobile (zero kinetic energy) and it is obvious that this is not the case for all substances. Therefore, a new temperature must be introduced that matches the measured kinetic energy with the traditional temperature. It will be the "absolute temperature" measured in Kelvin [K] whose equivalence kinetic energy / temperature measured is such that 0 [°C] corresponds to 273.15 [K].

Internal energy is a contribution to energy that does not appear in Classical Mechanics as we already know. From the macroscopic point of view, a container at rest that contains a fluid does not possess kinetic energy, while its potential energy is constant. We can ignore it by giving the value zero to this constant.

From the microscopic point of view, however, things change! Indeed, the atoms or molecules of the fluid are in motion and interact. It is necessary to associate to them an energy (the internal energy) which is the sum of the contributions relative to each atom.

Since then:

$$\boxed{PV=\frac{1}{3}Nmv^2+\frac{1}{3}\sum_{i\neq j}\vec{F}_{ij}\circ\vec{r}_{ij}=NkT+\frac{1}{3}\sum_{i\neq j}\vec{F}_{ij}\circ\vec{r}_{ij}} \tag{9.7.675}$$

It is the "general equation of state of a real gas", that is, the equation of state which takes into account the interactions between molecules. It is interesting to notice that finally this relation can allow us to calculate the energy of the gas even if there are no walls!

If the gas is perfect, there are no interactions between the N molecules (by hypothesis) and then we fall back on the "ideal gas law" as follows:

$$PV=NkT \tag{9.7.676}$$

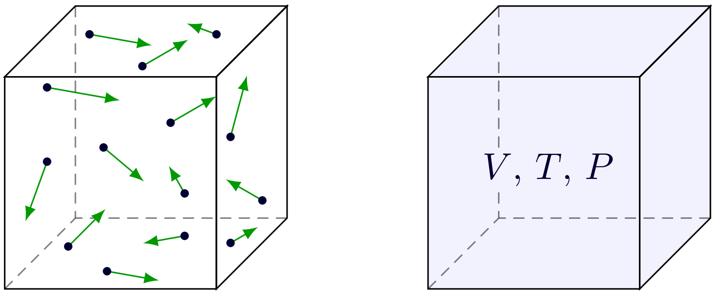
where P is the absolute pressure of the gas, N is the number of molecules in the given volume V and k (written k_B if there is a risk of confusion) is the Boltzmann constant:

$$k=1.38064852(79)\cdot 10^{-23}\,[\mathbf{J}\cdot\mathbf{K}^{-1}] \tag{9.7.677}$$

That we find much more frequently in the form:

$$\boxed{PV=NkT=n\frac{N}{n}T=nRT} \tag{9.7.678}$$

if n is expressed in moles with R the constant of the perfect gases. Obviously for $n=1$, N is equal to the number of particles in one mole (Avogadro's number: N_{A}).



Remark

If you assume air is an ideal gas (as it is often done at standard temperature and pressure), then one mole occupies at the sea level:

$$V=\frac{nRT}{P}=\frac{1\cdot 8,314\cdot 298}{101,325}\cong 0.0245\,[\text{m}^3] \tag{9.7.679}$$

Thus, each atom occupies statistically a volume of:

$$\frac{V}{N_a}=\frac{V}{6.023\cdot 10^{23}}\cong 4\cdot 10^{-26}\,[\text{m}^3] \tag{9.7.680}$$

The spacing between atoms is on the order of the cube root of that, or ~ 3 [nm] (the same calculation for the stratosphere leads to a value of ~ 6 [nm]). However this distance isn't the size of the atoms (if you assume wrongly that it is the case you would get a sectional surface of the order of 10^{-17})! Indeed, advanced calculations give for O_2 a Rayleigh cross-section of approximately $6\cdot 10^{-25}\,[\text{m}^{-2}]$ for light wavelength between 185 and 187 [nm] (see [494]). Keep in mind that Hughes and Jauncey, Phys. Rev. (36 1930), 773 have shown experimentally that for visible light, light to light scattering is $\sim 10^{-64}\,[\text{m}^{-2}]$.

If the temperature is constant, we fall back on "Boyle-Mariotte's law":

$$PV=c^{te} \tag{9.7.681}$$

Before continuing we can also come back on Avogadro statement: "equal volumes of all gases, at the same temperature and pressure, have the same number of molecules". That is to say for a given mass of an ideal gas, the volume and amount (moles) of the gas are directly proportional if the temperature and pressure are constant which can be written as:

$$V\propto n \tag{9.7.682}$$

or:

$$\frac{V}{n}=c^{te} \tag{9.7.683}$$

This law describes how, under the same condition of temperature and pressure, equal volumes of all gases contain the same number of molecules. For comparing the same substance under two different sets of conditions, the law can be usefully expressed as follows:

$$\frac{V_1}{n_1}=\frac{V_2}{n_2}=c^{te} \tag{9.7.684}$$

The most significant consequence of Avogadro's law is that the ideal gas constant has the same value for all gases. This means that:

$$\frac{P_1V_1}{T_1n_1}=\frac{P_2V_2}{T_2n_2}=c^{te} \tag{9.7.685}$$

To arrive at the perfect gas equation, it is useful to remember that we have made implicitly three hypotheses:

H1. The molecules are assimilated to hard spheres whose diameter is negligible in comparison with the average distance between them. That is what we name the "structural hypothesis".

H2. Ultimately, and this is what we have learned, if we consider molecules as punctual, the possibility of interaction between the particles vanishes. The only remaining interactions will be shocks on the walls of the tank that contains the gas. These shocks are perfectly elastic so that we can apply the laws of conservation of the momentum of kinetic energy. This is what we name the "interactive hypothesis limit"

H3. The gas is studied in a state of thermodynamic equilibrium, which results in the homogeneity of intensive and extensive variables. That is what we name the "hypothesis of molecular chaos".

In a particular case, if the interactions are derived from a central potential:

$$\vec{F}_{ij}=-\frac{\partial E_(r_{ij})}{\partial r_{ij}}\vec{u}_{ij} \tag{9.7.686}$$

We can rewrite this as follows:

$$F_{ij}r_{ij}=-r_{ij}\frac{\partial E_(r_{ij})}{\partial r_{ij}} \tag{9.7.687}$$

If in addition the potential energy is of the type (be careful not to confuse the parameter k with the Boltzmann constant denoted in the same way!):

$$E_p(r_{ij})=\frac{k}{\partial r_{ij}} \tag{9.7.688}$$

Then we have:

$$F_{ij}r_{ij}=-r_{ij}\frac{\partial E_(r_{ij})}{\partial r_{ij}}=-r_{ij}\left(-\frac{k}{r_{ij}^2}\right)=\frac{k}{r_{ij}}=E_p(r_{ij}) \tag{9.7.689}$$

And therefore:

$$PV=NkT+\frac{1}{3}\sum_{i\neq j}\vec{F}_{ij}\circ\vec{r}=NkT+\frac{1}{3}E_p \tag{9.7.690}$$

Where E_p is then mean total energy of the system.

In fact, care must be taken that we have not rigorously proved the ideal gas law. Indeed, when we had put earlier above:

$$E_c=\frac{1}{2}mv^2=\frac{3}{2}kT \tag{9.7.691}$$

This implicitly assumed that the perfect gas equation was already known (...).

This approach to gas kinetics is interesting because it is useful in astrophysics. However, this is by far not the simplest in a school context and pedagogically... We propose the reader to come back to these same results further below via the concepts of pressure and kinetic temperature once the Van der Waals equation is determined.

In 11875 (holocene calendar) the Dutch scientist J.D. Van der Waals tried to replace the perfect gas equation by a relation which would take into account the intermolecular forces and the size of the molecules. The first and most obvious correction to the equation of perfect gases:

$$PV=kNT \tag{9.7.692}$$

is to subtract the volume of the gas molecules from volume V. We can do this logically by replacing V by $V-Nb$ where b is a very small constant, which obviously represents the average volume per molecule (tables exist for this). So:

$$P=\frac{kNT}{V-Nb} \tag{9.7.693}$$

where the term Nb is commonly referred to as the "covolume".

To take account of the intermolecular forces that we have previously neglected, we can try an approximate approach by knowing already that the attraction force of each molecule will be on $N-1$ molecules. Consequently, the numerator of the attraction force will trivially contain (by the sum of all terms) if the gas is isotropic and homogeneous a term of the type $N(N-1)$ for the influence of all the molecules together which if N is very large can be approximated by N^2.

We also know that in the numerator there will be a mass term for each particle. If we know the ratio N/V then we only need to know the mass density of the gas (but this is not an extensive variable so we will avoid making it appear explicitly). Thus, the term N^2 can be directly written $(N/V)^2$.

Gas	**Chemical Formula**	**Molar mass** $[\mathbf{g\cdot mol^{-1}}]$	**Density** $[\mathbf{kg\cdot m^{-3}}]$
Air	-	28.96	1.2740
Ammonia	NH_3	17.03	0.7491
Argon	Ar	39.95	1.7572
Bio Gas	$35\%\ CO_2\ 65\%CH_4$	25.83	1.1363
Butane	C_4H_{10}	58.12	2.5567
Butylene	C_4H_8	56.11	2.4681
Carbon Dioxide	CO_2	44.01	1.9359
Carbon Monoxide	CO	28.01	1.2321
Chlorine	Cl_2	70.91	3.1205
Ethane	C_2H_6	30.07	1.3227
Ethylene	C_2H_4	28.05	1.2340
Helium	He	4.00	0.1761
Hexane	C_6H_{14}	86.18	3.7908
Hydrogen	H_2	2.02	0.0887
Methane	CH_4	16.04	0.7057
Nitrogen	NH_2	28.01	1.2323
Oxygen	O_2	32.00	1.4076
Pentane	C_5H_{12}	72.15	3.1738
Propane	C_3H_8	44.10	1.9397
Propylène	C_3H_6	42.08	1.8510
Sulfur Dioxide	CO_2	64.06	2.8191

Table 9.37: Densities of various typical gases at normal pressure and temperature

Remark

A gas can have a density higher than a liquid under certain conditions. This typically occurs at very high pressures and temperatures, where the gas reaches a state known as a supercritical fluid. In this state, the gas does not condense into a liquid but has a density similar to that of a liquid.

Following this reasoning, Van der Waals added to the right-hand side of the relation above a negative term proportional to the quantity $(N/V)^2$. The presence of this term results in a lowering of the pressure as the density of the gas increases. The modified relation is thus:

$$P \cong \frac{kNT}{V-Nb} - a\left(\frac{N}{V}\right)^2 \tag{9.7.694}$$

where a is a constant of proportionality. We can rewrite this relation in the form:

$$\boxed{\left(P + a\left(\frac{N}{V}\right)^2\right)(V-Nb) \cong kNT} \tag{9.7.695}$$

which is named the "Van der Waals state equation" or "Van der Waals real gas equation" (we find in the literature several equivalent ways of writing this last relation). It is an excellent description of the equation of state in a wide range of the variables P, V, T, the values a and b being characteristic of each gas. The constants a and b are determined experimentally as we have already mentioned.

We can represent the Van der Waals equation in a P-V diagram (hence constant temperature). Here is an example with CO_2 (carbon dioxide):

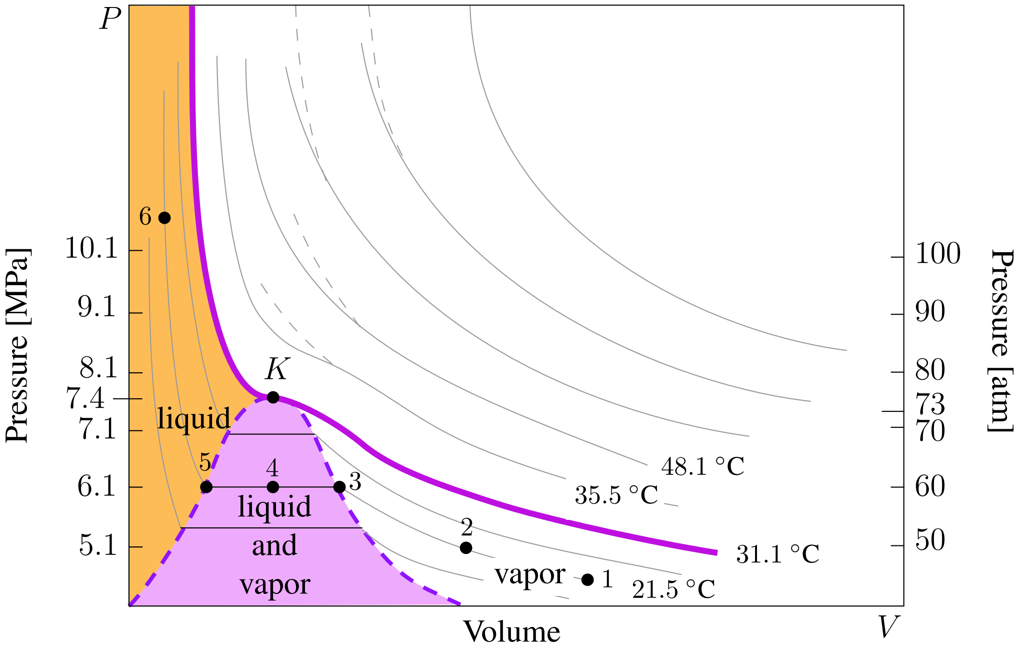


Figure 9.271: **Van der Waals P-V diagram for CO_2**

Which corresponds to:

$$P \cong \frac{kNT}{V-Nb} - a\frac{N^2}{V^2} \tag{9.7.696}$$

If we set $a=0$ and $b=0$ we see that we fall back on a famous relation...

The bottom figure shows the general case. One can pass from state F (vapour) to state I (liquid) by following a path passing through states A and E (liquefaction stage), then a phase transition is observed. If we follow another path, for example by using the isotherm $\overline{GH}$ ($T>T_k$, red path), there is no liquefaction stage, we pass continuously from the gaseous state to the liquid state:

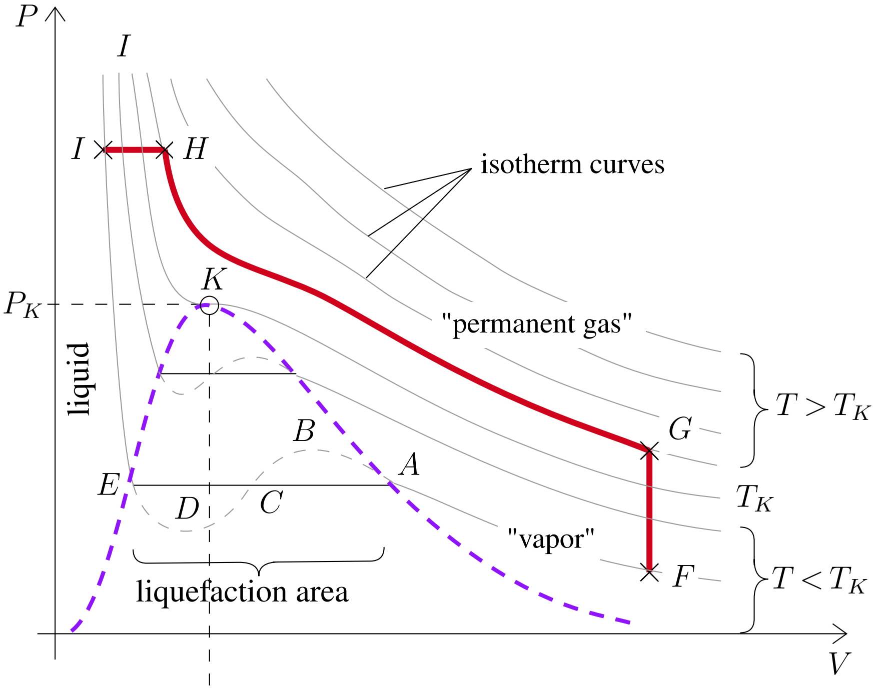

Figure 9.272: Van der Waals general P-V diagram

The Van der Waals equation can be put in the form of a virial type development using a Taylor-Maclaurin development (see section Sequences and Series page 1703):

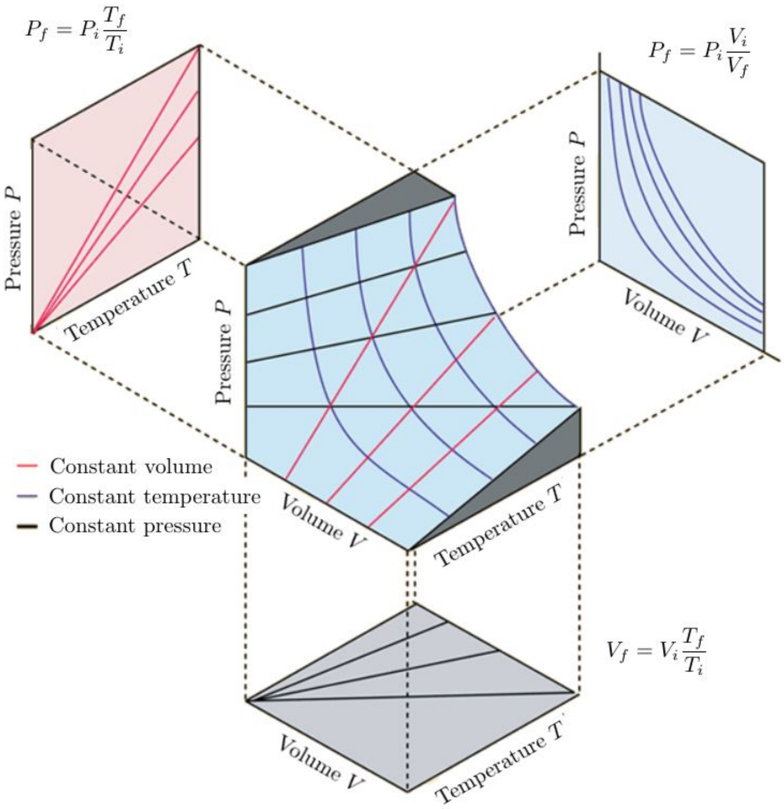
$$P\cong\frac{kNT}{V-Nb}-a\left(\frac{N}{V}\right)^2=\frac{kNT}{V(1-\dfrac{Nb}{V})}-a\left(\frac{N}{V}\right)^2=\frac{kNT}{V(1-\dfrac{Nb}{V})}-\frac{akNT}{V}\left(\frac{N}{kTV}\right)$$
$$=\frac{kNT}{V}\left(1+\frac{Nb}{V}+\frac{N^2b^2}{V^2}+\ldots\right)-\frac{akNT}{V}\left(\frac{N}{kTV}\right)\tag{9.7.697}$$

or by rearranging the terms:

$$P\cong\frac{kNT}{V}\left(1+\left(b-\frac{a}{kT}\right)\frac{N}{V}+b^2\frac{N^2}{V^2}+\ldots\right)\tag{9.7.698}$$

Let us notice that there exists a temperature for which the term $\left(b-\dfrac{a}{kT}\right)$ is zero. We name it the "Boyle temperature" of the gas: this is the temperature at which the actual gas behaves like an ideal gas.

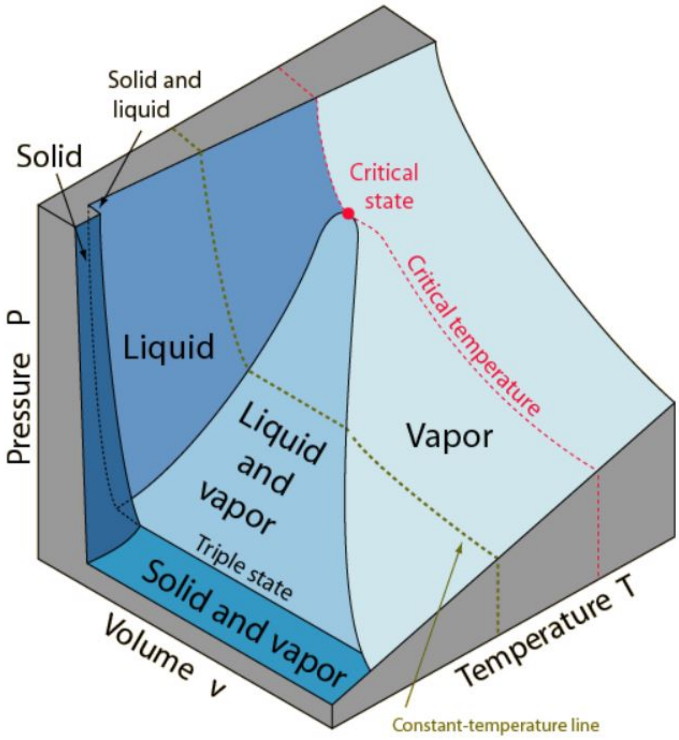
Form information here is for comparison a PVT diagram of the ideal gas law:



$P_f = P_i\frac{T_f}{T_i}$
Pressure P
Temperature T
$P_f = P_i\frac{V_i}{V_f}$
Pressure P
Volume V
Pressure P
Volume V
Temperature T
Constant volume
Constant temperature
Constant pressure
$V_f = V_i\frac{T_f}{T_i}$
Volume V
Temperature T

Figure 9.273: PVT **diagram of the ideal gas law**

And below a more realistic one where we can identify the Van der Waals law application domain:



Solid and liquid
Solid
Critical state
Critical temperature
Pressure P
Liquid
Liquid and vapor
Vapor
Triple state
Solid and vapor
Volume v
Temperature T
Constant-temperature line

Figure 9.274: PVT **phase diagram for real gas**

Notice that in the last figure there is a line named "triple state", seen in the PV side, it reduces to a well known point named the "triple point". Therefore the triple point of a substance is the temperature and pressure at which the three phases (gas, liquid, and solid) of that substance coexist in thermodynamic equilibrium. Most curious is the "critical point[41]" that results in a "critical state", also commonly named "critical superfluid", where vapour (gas) and liquid coexist and cannot be visually differentiate (this happens in a value of pressure and temperature that is not natural on Earth but possible on Saturn and Neptune).

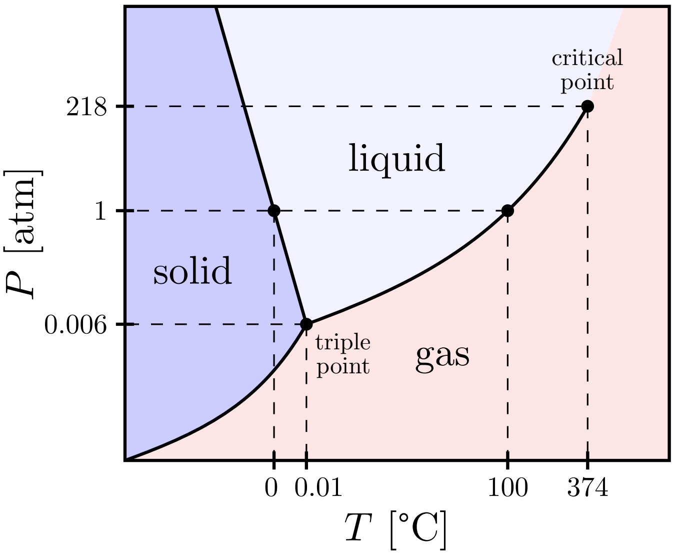


Figure 9.275: PVT **phase diagram for water** $\mathrm{H_2O}$ **(author: Izaak Neutelings)**

Here are some triple point PV values for some substances:

Substance	**Formula**	**Temperature [K]**	**Pressure [kPa]**
Carbon (graphite)	C	$4,765$	$10,132$
Carbon dioxide	CO_2	216.55	517
Deuterium	^2H	18.63	17.1
Hydrogen	H	13.84	7.04
Mercury	Hg	234.2	$1.65 \cdot 10^{-7}$
Methane	CH_4	90.68	11.7
Oxygen	O	54.36	0.152
Titanium	Ti	$1,941$	$5.3 \cdot 10^{-3}$
Water	H_2O	273.16	0.611657

Table 9.38: **PV triple point for some substances**

And.... keep always in mind that the phase diagram show always the state of a given substance for a given pressure, temperature (and volume) when its surrounding is the substance itself and not the air (common misconception)!!!!!!!

---

[41] There are nice videos on YouTube where you can see these states appears (i.e. the critical point and the triple point).

9.7.3.2.1 Equipartition theorem of energy derivation based on quantum physics and statistical mechanics

What we have seen above can also be demonstrated from purely quantum and statistical considerations. Let us see now for general culture (some parts of the development below seems to arise magically but the reader must keep in mind that the physicists who developed it know to what result they had to arrive... and therefore there wave likely some trial and errors) and also because some of the steps used below will be useful to us to derive the Sackur-Tetrode equation.

The internal energy U can be expressed using the canonical partition function Z_c.

At thermodynamic equilibrium as for the Maxwell-Boltzmann distribution (see section Statistical Mechanics 3561) we have:

$$U=\sum_{i=1}^{K}n_iE_i=\frac{N}{Z_c}\sum_{i=1}^{K}g_i\,e^{-E_i/(kT)}E_i \qquad (9.7.699)$$

with as a reminder by definition:

$$Z_c(T,V)=\sum_{i=1}^{K}g_i\,e^{-E_i/(kT)} \qquad (9.7.700)$$

We derive the partition function with respect to the temperature T at a constant volume V:

$$\left(\frac{\partial Z_c}{\partial T}\right)_V=\sum_{i=1}^{K}g_i\frac{E_i}{kT^2}e^{-E_i/kT}=\frac{1}{kT^2}\sum_{i=1}^{K}g_i\,e^{-E_i/kT}E_i \qquad (9.7.701)$$

Hence:

$$\sum_{i=1}^{K}g_i\,e^{-E_i/kT}E_i=kT^2\left(\frac{\partial Z_c}{\partial T}\right)_V \qquad (9.7.702)$$

Therefore:

$$U=\frac{NkT^2}{Z_c}\left(\frac{\partial Z_c}{\partial T}\right)_V=NkT^2\left(\frac{\partial\ln(Z_c)}{\partial T}\right)_V \qquad (9.7.703)$$

We consider the simplest gas, a monoatomic ideal gas of zero electric charge.

If we do not neglect the potential gravitational energy mgz in front of the kinetic energy of translation, the energy of the particles of this gas is written:

$$E_i=\frac{1}{2}mv_i^2=\frac{p_i^2}{2m} \qquad (9.7.704)$$

the speed v_i of each particle can vary from $-\infty$ to $+\infty$.

We will use the ideal gas model, where the potential interaction energy is neglected, and the particles are considered to be free. This is an approximation because without interaction between the particles, the gas could not evolve over time, and tend towards thermodynamic equilibrium.

The gas is in a chamber that is supposed to be parallel to the sides a, b, c, the walls of which are modelled by barriers of infinite potential. We have here in our model of potential energy, a three-dimensional flat well, of infinite depth:

$$U_i(\vec{r},t)=0 \text{ if } \begin{cases} a>x>0 \\ b>y>0 \\ c>z>0 \end{cases} \qquad U_i(\vec{r},t)=+\infty \text{ otherwise} \tag{9.7.705}$$

If moreover we go neglect the potential energy of gravity in front of the kinetic energy, then the potential energy is zero and the Schrödinger equation of the quanton in the enclosure is written (see section Quantum Wave Physics page 4772):

$$\frac{-\hbar^2}{2m}\Delta\psi_i=\mathrm{i}\hbar\frac{\partial\psi_i}{\partial t} \tag{9.7.706}$$

If the space and time variables are linked, they are only linked in the expression of the potential energy.

When the potential interaction energy U is independent of time and depends only on space, which is the case here since it is zero, the Schrödinger equation can be solved by the method of separation of space variables $\vec{r}$ and time t.

We then look for a solution of the form:

$$\psi_i(\vec{r},t)=\varphi_i(\vec{r})\,f_i(t) \tag{9.7.707}$$

Since the Laplacian Δ only applies to space variables, the Schrödinger equation becomes:

$$\frac{-\hbar^2}{2m}f_i(t)\,\Delta\varphi_i(\vec{r})=\mathrm{i}\hbar\,\varphi_i(\vec{r})\frac{\mathrm{d}f_i(t)}{\mathrm{d}t} \tag{9.7.708}$$

by dividing by $\varphi_i(\vec{r})\,f_i(t)$:

$$-\frac{\hbar^2}{2m}\frac{\Delta\varphi_i(\vec{r})}{\varphi_i(\vec{r})}=\mathrm{i}\hbar\frac{1}{f_i(t)}\frac{\mathrm{d}f_i(t)}{\mathrm{d}t} \tag{9.7.709}$$

We have a function of $\vec{r}$ which is equal to a function of t.

The only possibility is that they are equal to the same constant in space and time. The dimensional analysis shows that this constant is an energy, which can only be the internal energy ε_i of the quanton.

For the temporal part we have:

$$\begin{aligned} \mathrm{i}\hbar\frac{1}{f_i(t)}\frac{\mathrm{d}f_i(t)}{\mathrm{d}t}&=E_i \\ \frac{\mathrm{d}f_i(t)}{f_i(t)}&=-\frac{\mathrm{i}}{\hbar}E_i\,\mathrm{d}t \\ f_i(t)&=Ce^{-\mathrm{i}E_it/\hbar} \end{aligned} \tag{9.7.710}$$

and for the spatial part:

$$-\frac{\hbar^2}{2m}\frac{\Delta\varphi_i(\vec{r})}{\varphi_i(\vec{r})}=E_i \tag{9.7.711}$$

where we recognize the time independent Schrödinger equation.

The Laplacian being the sum of three operators each acting on a single space coordinate, we seek a solution with the space variables separated:

$$\varphi_i(\vec{r})=\varphi_{i1}(x)\,\varphi_{i2}(y)\,\varphi_{i3}(z) \tag{9.7.712}$$

Therefore:

$$\Delta\varphi_i(\vec{r})=\varphi_{i1}''(x)\,\varphi_{i2}(y)\,\varphi_{i3}(z)+\varphi_{i1}(x)\,\varphi_{i2}''(y)\,\varphi_{i3}(z)+\varphi_{i1}(x)\,\varphi_{i2}(y)\,\varphi_{i3}''(z) \tag{9.7.713}$$

Hence:

$$-\frac{\hbar^2}{2m}\left(\frac{\varphi_{i1}''(x)}{\varphi_{i1}(x)}+\frac{\varphi_{i2}''(y)}{\varphi_{i2}(y)}+\frac{\varphi_{i3}''(z)}{\varphi_{i3}(z)}\right)=E_i \tag{9.7.714}$$

The space coordinates being independent:

$$-\frac{\hbar^2}{2m}\frac{\varphi_{i1}''(x)}{\varphi_{i1}(x)}=E_{ix}\qquad -\frac{\hbar^2}{2m}\frac{\varphi_{i2}''(y)}{\varphi_{i2}(y)}=E_{iy}\qquad -\frac{\hbar^2}{2m}\frac{\varphi_{i3}''(z)}{\varphi_{i3}(z)}=E_{iz} \tag{9.7.715}$$

with:

$$E_i=E_{ix}+E_{iy}+E_{iz} \tag{9.7.716}$$

By defining:

$$k_{ix}^2=2mE_{ix}/\hbar^2\qquad k_{iy}^2=2mE_{iy}/\hbar^2\qquad k_{iz}^2=2mE_{iz}/\hbar^2 \tag{9.7.717}$$

we have the simple following particular solution:

$$\frac{\varphi_{i1}''(x)}{\varphi_{i1}(x)}=-k_{ix}^2\qquad \frac{\varphi_{i2}''(y)}{\varphi_{i2}(y)}=-k_{iy}^2\qquad \frac{\varphi_{i3}''(z)}{\varphi_{i3}(z)}=-k_{iz}^2 \tag{9.7.718}$$

Whose solutions are:

$$\begin{aligned}\varphi_{i1}(x)&=A_1\sin(k_{ix}x+\alpha_{ix})\\ \varphi_{i2}(y)&=A_2\sin(k_{iy}y+\alpha_{iy})\\ \varphi_{i3}(z)&=A_3\sin(k_{iz}z+\alpha_{iz})\end{aligned} \tag{9.7.719}$$

We make the non-trivial assumption that the wave function is zero on the walls of the enclosure.

For the first relation, the boundary condition at $x=0$ is written:

$$\varphi_{i1}(0)=A_1\sin(\alpha_{ix})=0\qquad \forall p_{ix}\in\mathbb{Z},\quad \alpha_{ix}=p_{ix}\pi \tag{9.7.720}$$

and, on $x=a$:

$$\varphi_{i1}(a)=A_1\sin(k_{ix}a+p_{ix}\pi)=0\Leftrightarrow k_{ix}=n_{ix}\frac{\pi}{a} \tag{9.7.721}$$

where we define in a very tricky way.... n_{ix} as an integer such that:

$$\begin{aligned}n_{ix}&=\frac{a}{\pi}k_{ix}\\ &=\frac{a}{\pi\hbar}\sqrt{2mE_{ix}}\\ &\leqslant\frac{2a}{h}\sqrt{2mE_i}\end{aligned} \tag{9.7.722}$$

n_{ix} is therefore a positive integer that has for maximum value $2a\sqrt{2mE_i}/h$.

For the three relations we then define:

$$k_{ix} = n_{ix}\frac{\pi}{a} \qquad k_{iy} = n_{iy}\frac{\pi}{b} \qquad k_{iz} = n_{iz}\frac{\pi}{c} \tag{9.7.723}$$

The energy E_i of the i^{th} quanton is therefore quantified, and has for expression:

$$\begin{aligned} E_i &= E_{ix} + E_{iy} + E_{iz} \\ &= \frac{\hbar^2}{2m}\left(k_{ix}^2 + k_{iy}^2 + k_{iz}^2\right) \\ &= \frac{\hbar^2\pi^2}{2m}\left(\frac{n_{ix}^2}{a^2} + \frac{n_{iy}^2}{b^2} + \frac{n_{iz}^2}{c^2}\right) \\ &= \frac{h^2}{8m}\left(\frac{n_{ix}^2}{a^2} + \frac{n_{iy}^2}{b^2} + \frac{n_{iz}^2}{c^2}\right) \end{aligned} \tag{9.7.724}$$

The above equality gives the set of quantum states accessible to a quanton of energy E_i. We can write it after rearrangement:

$$\frac{h^2}{8m}\left(\frac{n_{ix}^2}{a^2\varepsilon_i} + \frac{n_{iy}^2}{b^2\varepsilon_i} + \frac{n_{iz}^2}{c^2\varepsilon_i}\right) = 1 \tag{9.7.725}$$

which is of the shape:

$$\frac{x^2}{A^2} + \frac{y^2}{B^2} + \frac{z^2}{C^2} = 1 \tag{9.7.726}$$

with:

$$x = n_{ix} \qquad y = n_{iy} \qquad z = n_{iz} \tag{9.7.727}$$

$$A^2 = \frac{8ma^2\,E_i}{h^2} \qquad B^2 = \frac{8mb^2\,E_i}{h^2} \qquad C^2 = \frac{8mc^2\,E_i}{h^2} \tag{9.7.728}$$

It is the equation of an ellipsoid of parameters A, B, C (lengths of the three half-axes). Each point of integer coordinates (n_{ix}, n_{iy}, n_{iz}) inside the ellipsoid, represents a quantum state accessible to a quanton of energy E_i. The quantum numbers n_{ix}, n_{iy} and n_{iz} being positive, we only take into account the eighth $(\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2})$ of the ellipsoid volume. The factor of degeneration is then given by:

$$\begin{aligned} g_i &= \frac{1}{8}\cdot V_{\text{ellipsoid}} = \frac{1}{8}\cdot\frac{4}{3}\pi\,ABC \\ &= \frac{\pi}{6}\cdot\frac{a}{h}\sqrt{8mE_i}\cdot\frac{b}{h}\sqrt{8mE_i}\cdot\frac{c}{h}\sqrt{8mE_i} \\ &= \frac{\pi\,abc\,(8mE_i)^{3/2}}{6h^3} \\ &= \frac{4\pi\,V\,(2mE_i)^{3/2}}{3h^3} \\ &= \frac{4\pi\,V\,p^3}{3h^3} \\ &= \frac{1}{h^3}\cdot V\cdot\frac{4}{3}\pi p^3 \end{aligned} \tag{9.7.729}$$

Let us interpret this result: Let us consider the 6-dimensional hyperspace $(\vec{r},\vec{p})$, named as we know the "phase space". The hyper-volume of this space is constituted by the multiplication of the volume V of ordinary space and the volume of the space of the quantities of movement $4/3\cdot\pi p^3$.

In Cartesian coordinates the degeneracy factor is written:

$$g_i=\frac{\displaystyle\int_x\int_y\int_z\int_{p_x}\int_{p_y}\int_{p_z}\mathrm{d}x\mathrm{d}y\mathrm{d}z\mathrm{d}p_x\mathrm{d}p_y\mathrm{d}p_z}{h^3} \qquad (9.7.730)$$

Let's go back to the partition function:

$$\begin{aligned}Z_c&=\frac{1}{h^3}\int_x\int_y\int_z\int_{p_x}\int_{p_y}\int_{p_z}e^{-E_i/(kT)}\mathrm{d}x\mathrm{d}y\mathrm{d}z\mathrm{d}p_x\mathrm{d}p_y\mathrm{d}p_z\\&=\frac{m^3V}{h^3}\int_{v_x}\int_{v_y}\int_{v_z}e^{-m(v_x^2+v_y^2+v_z^2)/(2kT)}\mathrm{d}v_x\mathrm{d}v_y\mathrm{d}v_z\\&=\frac{m^3V}{h^3}\left[\int_{-\infty}^{+\infty}e^{-mv^2/(2kT)}\mathrm{d}v\right]^3\end{aligned} \qquad (9.7.731)$$

We put $a=m/(2kT)$:

$$Z_c=\frac{m^3V}{h^3}\left[\int_{-\infty}^{+\infty}e^{-av^2}\mathrm{d}v\right]^3 \qquad (9.7.732)$$

Using the result of the Gauss integral (see section Statistics page 695):

$$\int_{-\infty}^{+\infty}e^{-ax^2}\mathrm{d}x=\sqrt{\frac{\pi}{a}} \qquad (9.7.733)$$

Therefore we get the following canonical partition function for a monoatomic classical ideal gas:

$$Z_c=\frac{m^3V}{h^3}\left(\sqrt{\frac{2kT\pi}{m}}\right)^3=\frac{V}{h^3}(2\pi mkT)^{3/2} \qquad (9.7.734)$$

Z_c is therefore a function of the temperature T and the volume V :

$$Z_c=Z_c(T,V) \qquad (9.7.735)$$

Let us now express the internal energy of translation U. Starting from;

$$Z_c=\frac{V}{h^3}(2\pi mkT)^{3/2} \qquad (9.7.736)$$

Taking the natural logarithm:

$$\ln(Z_c)=\ln\left(\frac{V}{h^3}\right)+\frac{3}{2}\ln(2\pi mkT) \qquad (9.7.737)$$

Therefore:

$$\left(\frac{\partial \ln(Z_c)}{\partial T}\right)_V = \frac{3}{2T} \tag{9.7.738}$$

Remembering that just earlier above we have derived:

$$U = \frac{NkT^2}{Z_c}\left(\frac{\partial Z_c}{\partial T}\right)_V = NkT^2\left(\frac{\partial \ln(Z_c)}{\partial T}\right)_V \tag{9.7.739}$$

So finally:

$$\boxed{U = \frac{3}{2}NkT} \tag{9.7.740}$$

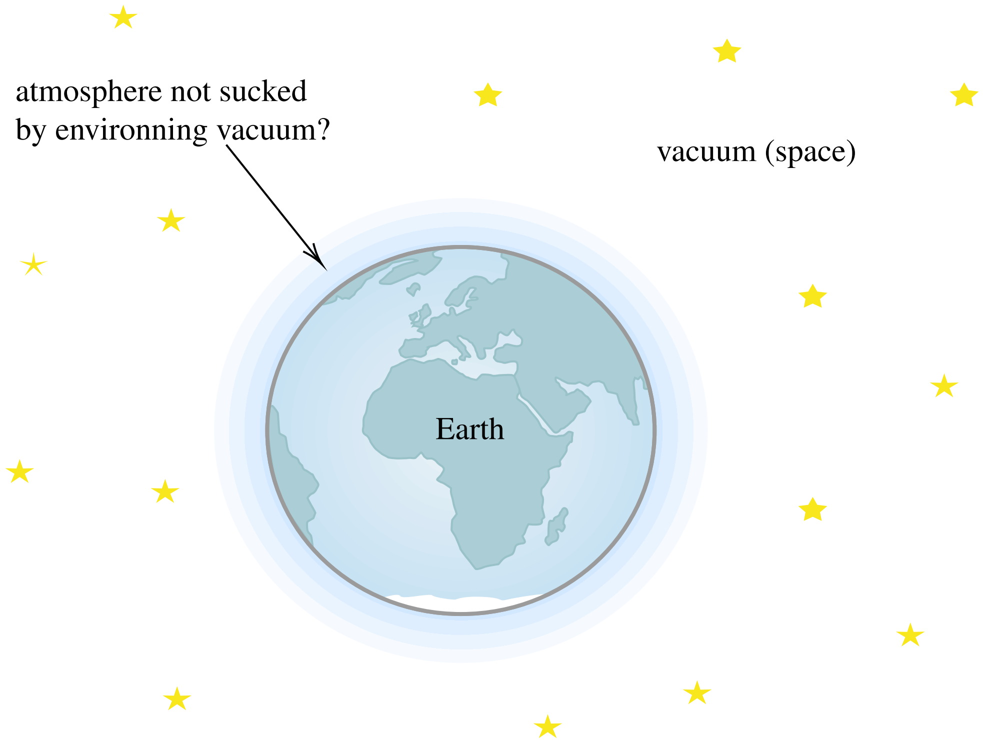
Now that we have the two relations, i.e. the equipartition energy for a monoatomic particle:

$$E_c = \frac{3}{2}NkT \tag{9.7.741}$$

But also the escape velocity (see section Mechanics page 3234):

$$v_e = \sqrt{\frac{2Gm}{R^2}R} = \sqrt{\frac{2Gm}{R}} \tag{9.7.742}$$

We can now easily understand why Earth's atmosphere is not sucked by its surrounding vacuum!



Anyway the question is quite dumb as vacuum does not suck like many believe, it's the atmosphere pushing into the space of the vacuum. A sealed empty container under water does not such the water in when we open it. It's the water pushing into the container! A vacuum doesn't suck, it just doesn't push back.

For Earth that gives us an escape velocity of $11,179.365\,[\mathrm{m}\cdot\mathrm{s}^{-1}]$. And using the equipartition energy in the most favorable (highest temperature ever measure of troposphere and lightest significant molecule that is nitrogen N_2) case we have:

$$v=\sqrt{\frac{3kT}{m}}=\sqrt{\frac{3\cdot 1.380649\cdot 10^{-23}\cdot 329.15}{4.652\cdot 10^{-26}}}\cong 541\,[\mathrm{m}\cdot\mathrm{s}^{-1}] \qquad (9.7.743)$$

So it's far from being enough for the atmosphere to escape Earth's attraction!

9.7.3.3 Kinetic Pressures (kinetic theory of gases)

The kinetic theory describe a gas as a large number of submicroscopic particles (atoms or molecules), all of which are in constant rapid motion that has randomness arising from their many collisions with each other and with the walls of the container.

Kinetic theory explains macroscopic properties of gases, such as pressure, temperature, viscosity, thermal conductivity, and volume, by considering their molecular composition and motion. The theory posits that gas pressure is due to the impacts, on the walls of a container, of molecules or atoms moving at different velocities.

Kinetic theory defines temperature in its own way, not identical with the thermodynamic definition.

Let us seek the number of molecules of a perfect gas, all supposed to be animated by an equal speed v, which strike a surface S for a duration $\mathrm{d}t$.

If the gas studied is in a state of thermodynamic equilibrium, this will result in the homogeneity of the intensive variables (hypothesis of molecular chaos).

It follows that the density of the particles is constant:

$$N_v = \frac{N}{V} = c^{te} \tag{9.7.744}$$

If we admit that the molecules are in motion, we shall assume that there is isotropy of velocities. In other words, since the velocities can be described in a system of 3 orthogonal axes (three spatial dimensions), there are 6 possible primary directions in total (2 directions per axis: forward, backward ...) .

This translates into equivalence between the different directions. There is:

$$\frac{N_v}{6} \tag{9.7.745}$$

particles having a velocity v along one of the primary directions.

Thus, during a time $\mathrm{d}t$, the surface S of the wall is percussed only by a part of the molecules contained in the volume $Sv\mathrm{d}t$ Indeed, only $1/6$ of the molecules contained in this volume are actually directed towards the surface S.

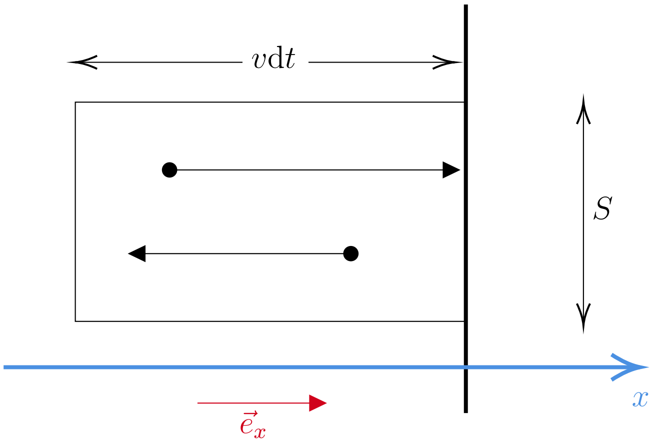


Figure 9.276: One of the walls of the enclosure (tank)

The number of molecules which strike the wall during the duration $\mathrm{d}t$ is thus:

$$\frac{1}{6}N_vSv\mathrm{d}t \tag{9.7.746}$$

Let us now study the dynamics of the impact of a particle on the wall!

The particle of a mass m arriving on the wall with the speed $\vec{v}_x$ goes away again with a speed $-\vec{v}_x$ if the shock is perfectly elastic.

The variation of the momentum of the particle is thus:

$$\Delta\vec{p}_{\text{wall}}=-m(\vec{v}_f-\vec{v}_i)=2mv\vec{e}_x \tag{9.7.747}$$

$$\Delta\vec{p}_{\text{molecule}}=m(\vec{v}_f-\vec{v}_i)=m((-\vec{v}_x)-\vec{v}_x)=-2mv\vec{e}_x \tag{9.7.748}$$

Following the conservation of the linear momentum, this linear momentum is transferred to the wall: the variation of the quantity of motion undergone by the wall is the opposite of that of the particle:

$$\Delta\vec{p}_{\text{wall}}=-m(\vec{v}_f-\vec{v}_i)=2mv\vec{e}_x \tag{9.7.749}$$

The total variation of the linear momentum of all the particles which strike the wall during the period $\mathrm{d}t$ is then equal in norm to:

$$\mathrm{d}p=(2mv)\frac{1}{6}N_vSv\mathrm{d}t \tag{9.7.750}$$

Applying the fundamental principle of dynamics, we can pass to the force undergone by the wall during the striking of these molecules:

$$F=\frac{\mathrm{d}p}{\mathrm{d}t} \tag{9.7.751}$$

therefore:

$$F=\frac{1}{3}N_vSmv^2 \tag{9.7.752}$$

Now by defining the pressure and taking the module: But by definition of the pressure and taking the module:

$$P=\frac{F}{S} \tag{9.7.753}$$

we then have the "kinetic pressure" given by:

$$\boxed{P=\frac{1}{3}N_v mv^2} \tag{9.7.754}$$

The kinetic pressure is therefore nothing else than the frequency of the shocks of the particles (molecules) on the wall. The more molecules (term in N_v) and the quicker they are (term in v), the more the number of shocks increases. This is consistent with experience and intuition.

9.7.3.4 Kinetic Temperature

Now comes the proof we are waiting from since the beginning of our study of gas: the proof that temperature (at a molecular or atomic level) is nothing more that a quantity related to the average velocity but with a conversion factor that is nothing else than the Boltzmann constant! Obviously we will see that there is a more precise definition of temperature in the section of Thermodynamics as the result that follows doesn't apply at the quantum level.

For this purpose we start again from:

$$P=\frac{1}{3}N_v mv^2 \tag{9.7.755}$$

By replacing N_v by the quotient N/V, the preceding relation can be written as:

$$PV=\frac{1}{3}Nmv^2 \tag{9.7.756}$$

If we identify it with the perfect gas state equation presented earlier above:

$$PV=nRT \tag{9.7.757}$$

it comes:

$$\frac{1}{3}Nmv^2=nRT \tag{9.7.758}$$

But the quantity of moles n is equal to the ratio of the number of particles to the number of Avogadro as we know:

$$n=\frac{N}{N_{\text{A}}} \tag{9.7.759}$$

which makes it possible to define the "kinetic temperature" by:

$$T_k=\frac{1}{3}\frac{N}{n}\frac{mv^2}{R}=\frac{1}{3}\frac{N_{\text{A}}mv^2}{R} \tag{9.7.760}$$

We then fall back on a way to introduce "Boltzmann constant" and such that:

$$k=\frac{R}{N_{\text{A}}}=1.38064852\cdot 10^{-23}\,[\text{J}^2\cdot\text{K}^{-1}] \tag{9.7.761}$$

The expression of kinetic temperature then takes the form:

$$\boxed{T_k=\frac{mv^2}{3k}} \tag{9.7.762}$$

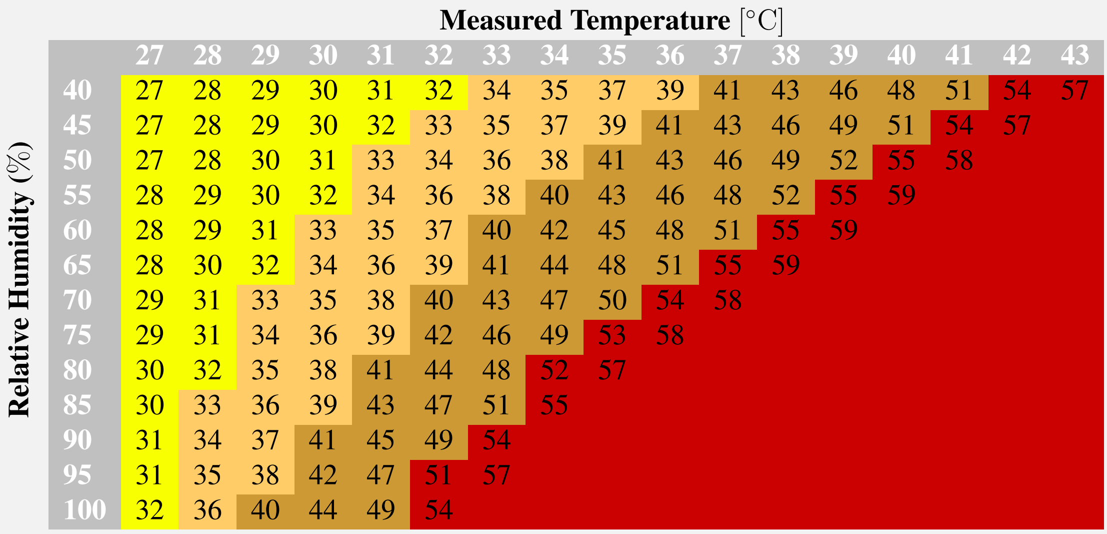
We can see that it seems the temperature can range from $]0,+\infty[$. However as we will see in the section of Quantum Mechanics an absolute temperature of zero cannot be reached because of the Heisenberg uncertainty principle. We also don't have experimental evidence yet for an upper limit for temperature.

Notice that the physical relation above doesn't gives us any threshold to define what is "hot" and what is "cold". Indeed, these two concepts are completely subjective to every human is not even precisely defined by any ISO standard (don't forget as already mentioned in the Introduction chapter of that book that it is not because a word exist in human vocabulary that the underlying concept has a physical reality!). The nearest thing we can find is the ISO 13732-1 *Ergonomics of the thermal environment - Methods for the assessment of human responses to contact with surfaces*. Especially the chapter *5.2 Identification of hot touchable surface* and the Part 3 treating of *Cold surfaces*. But no precise temperatures are given, only a protocol to define it statistical based on a test group.

This relationship shows that the kinetic temperature is only the representation of the kinetic energy of the particles (whose temperature is in fact a measure of the average velocity of the molecules). Imaginatively, it is the image of the violence of shocks. We can also better understand the origin of the definition of absolute temperature (otherwise, the velocity should be a complex number) and the argument that everything is immobile at absolute zero!

Remark

The kinetic temperature must not be confused with the "heat index" (HI), also named "feel/like temperature", that combines air temperature and relative humidity, in shaded areas, to posit a human-perceived equivalent temperature, as how hot it would feel if the humidity were some other value in the shade. Indeed, the human body normally cools itself by perspiration, or sweating. Heat is removed from the body by evaporation of that sweat. However, high relative humidity reduces the evaporation rate. This results in a lower rate of heat removal from the body, hence the sensation of being overheated (indeed you won't feel the same in a 323 [K] standard air without wind than in water being at the same temperature... and that's also why most human fail by estimating the temperature of different materials even if they are all... at the same temperature!). This effect is subjective, with different individuals perceiving heat differently for various reasons (such as differences in body shape, metabolic differences, differences in hydration, pregnancy, menopause, effects of drugs and/or drug withdrawal); its measurement has been based on subjective descriptions of how hot subjects feel for a given temperature and humidity (it's strongly related to the "heat capacity", i.e. the amount of energy that must be added or removed, in the form of heat, to one unit of mass of a substance in order to cause an increase or decrease of one unit in its temperature). This results in a heat index that relates one combination of temperature and humidity to another. The National Oceanic and Atmospheric Administration provides a double entry table (relative humidity + temperature) to extract a feel-like temperature, some other countries use - quite different - empirical formulas like the one below:



Relative Humidity (%) \ Measured Temperature [°C]	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	42	43
40	27	28	29	30	31	32	34	35	37	39	41	43	46	48	51	54	57
45	27	28	29	30	32	33	35	37	39	41	43	46	49	51	54	57	
50	27	28	30	31	33	34	36	38	41	43	46	49	52	55	58		
55	28	29	30	32	34	36	38	40	43	46	48	52	55	59			
60	28	29	31	33	35	37	40	42	45	48	51	55	59				
65	28	30	32	34	36	39	41	44	48	51	55	59					
70	29	31	33	35	38	40	43	47	50	54	58						
75	29	31	34	36	39	42	46	49	53	58							
80	30	32	35	38	41	44	48	52	57

100	32	36	40	44	49	54											

🟨 Discomfort
🟧 Extreme discomfort
🟫 Danger
🟥 Extreme Danger

Table 9.39: **Temperature felt based on measured temperature and humidity**

Thus the energy of a perfect gas is reduced to the sum of the kinetic energies of the particles which constitute it:

$$U=\sum_i \frac{1}{2}mv_i^2=\frac{N}{2}mv^2=\frac{3}{2}NkT=\frac{3}{2}nRT \tag{9.7.763}$$

The atoms of a monoatomic perfect gas can be assimilated to material points. Their kinetic energy is a kinetic energy of translation whose mean value, per atom, is written:

$$E_c=\frac{1}{2}mv^2=\frac{3}{2}kT \tag{9.7.764}$$

In the velocity space, all directions are equivalent! There is isotropy of the velocity distribution. In Cartesian coordinates, it comes:

$$v^2=v_x^2+v_y^2+v_z^2 \tag{9.7.765}$$

and as a result of isotropy:

$$v_x^2=v_y^2=v_z^2=\frac{1}{3}v^2 \tag{9.7.766}$$

hence:

$$E_{c,x}=E_{c,y}=E_{c,z}=\frac{1}{2}kT \tag{9.7.767}$$

Thus, the average kinetic energy per degree of freedom of translation is equal to:

$$E_{c,\text{df}}=\frac{1}{2}kT \tag{9.7.768}$$

The reader will of course notice that we obtain here the same results and conclusions as in our study of the virial theorem with the difference that the approach here is simpler and therefore more didactic.

9.7.3.5 Amagat and Dalton's law

Let us consider a mixture of two perfect gases in a volume V imposed constant at constant temperature T also imposed. We can write for each of the gases:

$$P_1V = n_1RT \qquad P_2V = n_2RT \tag{9.7.769}$$

Where P_1, P_2 are named "partial pressures". The whole mixture will be written:

$$PV = nRT = (n_1 + n_2)RT \tag{9.7.770}$$

But:

$$(n_1 + n_2)RT = n_1RT + n_2RT = P_1V + P_2V \tag{9.7.771}$$

and therefore:

$$(P_1 + P_2)V = (n_1 + n_2)RT \tag{9.7.772}$$

Finally we conclude that:

$$\boxed{P_{V,T} = P_1 + P_2} \tag{9.7.773}$$

The pressure of a mixture of two perfect gases is the sum of the partial pressures, this is the "Dalton's law" also named "Dalton's law of partial pressures".

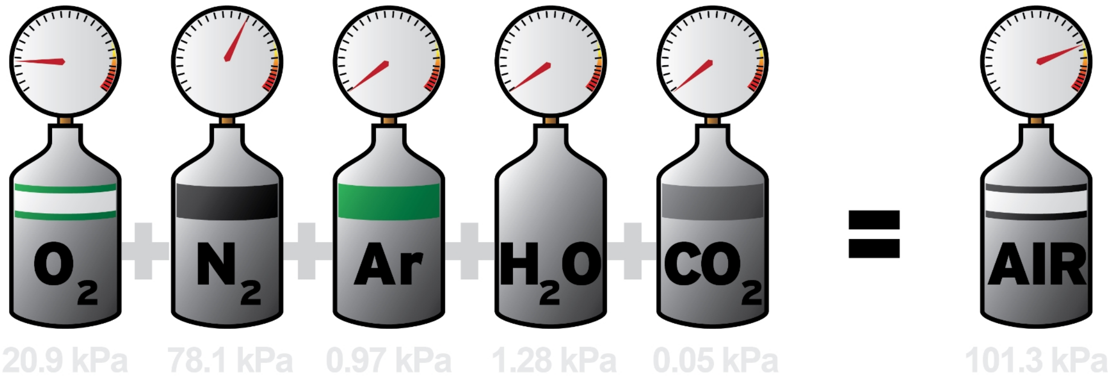

Figure 9.277: **Dalton's law illustration for air at normal temperature**

> **Remark**
>
> We mentioned in the section Thermodynamics that pressure was an intensive variable and therefore not additive. But this is not the case in the situation of perfect gases when the volume is forced as being constant.

Thus, the partial pressure P_i of a gas in a mixture is equal to the product of the total pressure P of the mixture by the percentage (concentration) c_i of the gas considered in the mixture:

$$P_i = c_iP \tag{9.7.774}$$

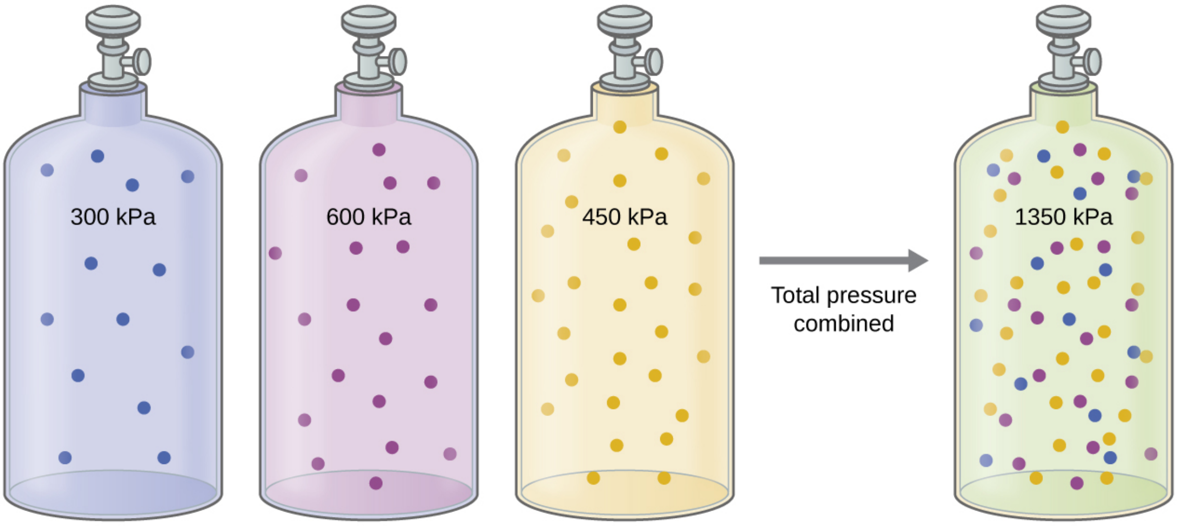

Figure 9.278: Numerical application of Dalton's law (source: OpenStax)

We can make the same reasoning at constant pressure P and constant temperature T. We then get:

$$P(V_1+V_2)=(n_1+n_2)RT \quad (9.7.775)$$

hence:

$$\boxed{V_{T,P}=V_1+V_2} \quad (9.7.776)$$

The volume of a mixture of two perfect gases at constant pressure and constant temperature is the sum of the partial volumes, it is the "Amagat's law".

9.7.3.6 Mean free path (in kinetic theory)

The mean free path is the average distance travelled by a moving particle (such as an atom, a molecule, a photon) between successive impacts (collisions), which modify its direction or energy or other particle properties.

We will now see a very interesting case study of gases which makes it possible to clarify a lot of misunderstandings in everyday life (smoke in restaurants, heat near a radiator, ...). However, the phenomena are in reality more complex, it is also necessary to take into account diffusion, convection, etc (see section Thermodynamics page 3634).

Consider a molecule, which moves at the average speed $\bar{v}$. Its sphere of influence V_i then sweeps, during the unit of time of its displacement, a volume (cylinder) given by:

$$V_i=\pi r^2\bar{v} \quad (9.7.777)$$

Remark

In the case of an atom or molecule as a sphere of influence, it is often referred to as the "Van der Waals volume" and the associated "Van der Waals radius".

If the unit of volume contains n molecules (n has therefore the units of a volumetric density), the number of shocks (collisions) during the unit of time in this same unit of volume will then be obviously:

$$C=n\pi r^2\bar{v} \tag{9.7.778}$$

at least if the other spheres of influence were immobile ... So to take into account the movement of other spheres of influence, consider the figure below with three simplistic scenarios:

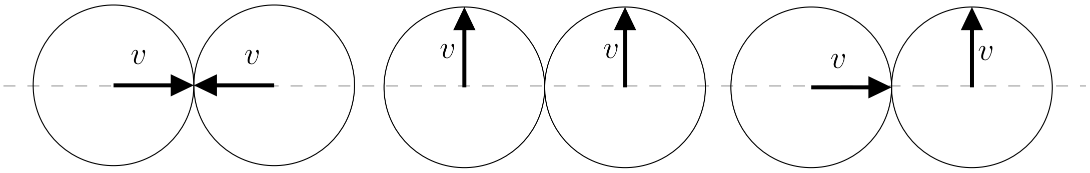

Figure 9.279: **Three collision scenarios**

From left to right we have:

1. The relative speed of the molecules is $2\bar{v}$
2. The relative speed of the molecules is zero
3. The relative speed of the molecules equals (Pythagoras) $\sqrt{2}\bar{v}$

The first two cases are somewhat extreme ... The third one will be considered as an average and can serve as a new basis for the previous calculation.

Thus, using the relative speed of the last scenario, the number of collisions during the unit of time in the unit volume becomes:

$$C=n\pi r^2\sqrt{2}\bar{v} \tag{9.7.779}$$

Thus, between two collisions a molecule travels an average distance:

$$\lambda=\frac{\bar{v}}{C}=\frac{1}{n\pi r^2\sqrt{2}} \tag{9.7.780}$$

It is therefore the expression of the mean free path as a function of the molecular (particle) density n (and not the number of moles!!!) and the radius r of the sphere of influence, the intrinsic parameter of the gas under consideration. The above relation is often written $\gamma=(n\sigma)^{-1}$ where σ is named the "scattering cross-section".

Given the ideal gas law:

$$PV=NkT \tag{9.7.781}$$

we have:

$$P=\frac{N}{V}kT=nkT \tag{9.7.782}$$

and therefore:

$$n=\frac{P}{kT} \tag{9.7.783}$$

Where n is still the molecular (particles) density (and not the number of moles !!!) and therefore we can write:

$$\boxed{\lambda=\frac{k}{\pi r^2\sqrt{2}}\frac{T}{P}} \tag{9.7.784}$$

A numerical application gives for the element at normal conditions of temperature and pressure a free mean path which for the majority of the current molecules is several thousands of times the diameter of a molecule of standard size (the mean free path is therefore of the micrometer[42]).

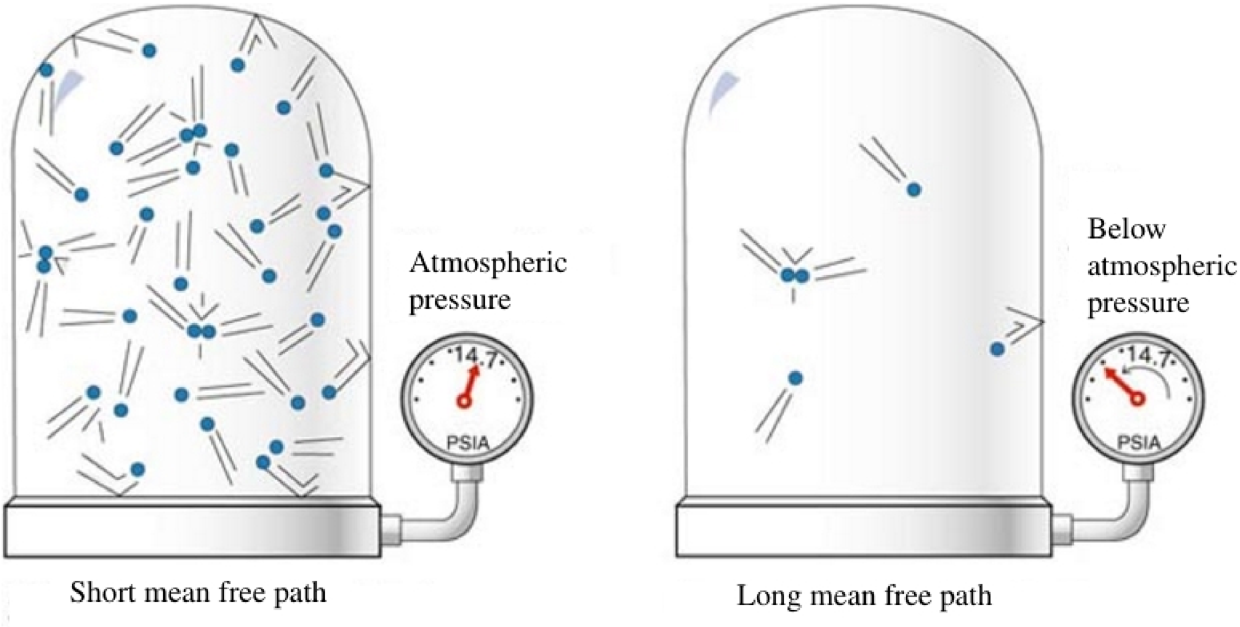

Figure 9.280: Simplified illustration of free mean path (source: ?)

Using the relation of the most probable mean velocity under the hypothesis of a Maxwell distribution of the velocities (see section Statistical Mechanics page 3554) we have:

$$\bar{v}=\sqrt{\frac{2kT}{m}}=\sqrt{\frac{2RT}{M_m}}\cong 389\,[\mathrm{m}\cdot\mathrm{s}^{-1}] \tag{9.7.785}$$

For a molecule with a molar mass of 30 [g] at normal temperature. This gives a number of collisions for one mole of molecules:

$$C=n\pi r^2\sqrt{2}\bar{v}\cong 15\cdot 10^6\,[\mathrm{s}^{-1}] \tag{9.7.786}$$

---

[42] In the section Principia we have given a table with a lot of examples of vacuum levels and their corresponding mean free path for recall...

This high frequency of collisions explains, under normal conditions of temperature and pressure, the rapidity with which the statistical equilibrium is established within a gas and also the speed of sound propagation.

At ambient temperature and for a vacuum of $7.5 \cdot 10^{-10}$ [Pa], we get with the same values a mean free path of approximately 1 [km].

The following table lists some typical values for air at different pressures at room temperature (remember by the way that 1 cubic meter is $1,000$ litres):

Pressure range	**Pressure** (hPa)	**Number density** (molecules $\cdot \mathrm{m}^{-3}$)	**Mean free path**
Ambient pressure	$1,013$	$2.7 \cdot 10^{25}$	$64 - 68$ nm[5]
Low vacuum	$300 - 1$	$10^{25} - 10^{22}$	$0.1 - 100\,\mu$m
Medium vacuum	$1 - 10^{-3}$	$10^{22} - 10^{19}$	$0.1 - 100$ mm
High vacuum	$10^{-3} - 10^{-7}$	$10^{19} - 10^{15}$	10 cm $- 1$ km
Ultra-high vacuum	$10^{-7} - 10^{-12}$	$10^{15} - 10^{10}$	1 km $- 10^5$ km
Extremely high vacuum	$< 10^{-12}$	$< 10^{10}$	$> 10^5$ km

Table 9.40: **Some typical free mean path for air**

Definition (#9.7.476): A "vacuum" is a region of space in which the density of matter is extremely low, meaning that it contains far fewer particles (atoms, molecules, ions, or dust) than ordinary matter. A perfect vacuum, defined as the complete absence of all matter, is an ideal concept that cannot be fully achieved in practice[43]. Even the best laboratory vacuums and the vast voids of interstellar space contain some particles and electromagnetic fields. In modern physics, the quantum vacuum is not truly empty either, as it is considered the lowest-energy state of a field and is characterized by transient quantum fluctuations.

Since the dimensions of the containers containing the gases being almost always less than this order of magnitude, it appears that when the vacuum is produced in a close volume, the intermolecular collisions are negligible vis-à-vis the molecule-wall collisions.

---

[43] The standard for vacuum technology vocabulary ISO 3529-1 defines a vacuum as a space with a gas pressure below atmospheric levels

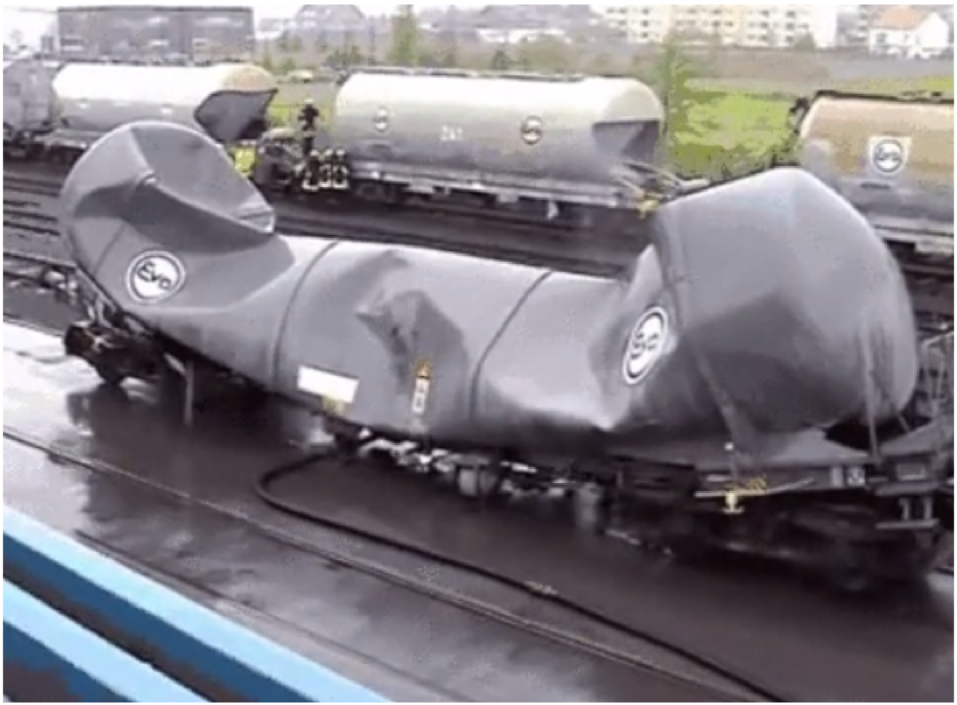

Figure 9.281: **Tank trailer vacuum implosion to atmospheric pressure (source: YouTube)**

Typical vacuums are designated according to the following convention:

Name	Pressure in Pascals
Coarse vacuum	10^5 to 100
Average vacuum	100 to 1
High vacuum (HV)	1 to 10^{-2}
Ultra high vacuum (UHV)	10^{-5} to 10^{-7}
Extreme high vacuum (XHV)	$< 10^{-7}$
Absolute emptiness	0 (no particles)

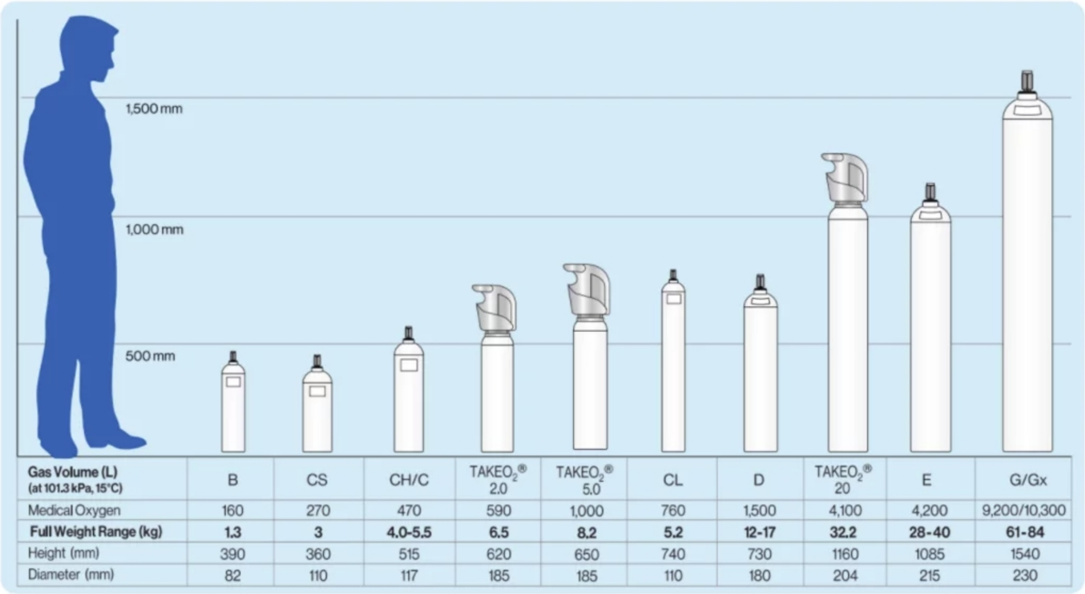
Table 9.41: **Different types of vacuum**

For a list of typical pressures (and vacuums) the reader can refer to the table at page 3101.

Caution! A vacuum on Earth does not suck like many believe, it's the atmosphere pushing into the space of the vacuum. A sealed empty container under water does not such the water in when we open it. It's the water pushing into the container! A vacuum doesn't suck, it just doesn't push back.

For people interesting in vacuum technologies and related mathematics, we strongly recommend the textbook *Vacuum and Ultravacuum: Physics and Technology* written by Igor Bello with 1063 pages (see [48]).

For information, an average human resting at sea level consumes roughly 378 to 660 liters of pure oxygen per day. As we know nowadays the technology to compress gases inside small volumes, in the image below the reader can see typical pressurised containers with their sizes and respective capacities:



Gas Volume (L) (at 101.3 kPa, 15°C)	B	CS	CH/C	TAKEO$_2$® 2.0	TAKEO$_2$® 5.0	CL	D	TAKEO$_2$® 20	E	G/Gx
Medical Oxygen	160	270	470	590	1,000	760	1,500	4,100	4,200	9,200/10,300
Full Weight Range (kg)	**1.3**	**3**	**4.0-5.5**	**6.5**	**8.2**	**5.2**	**12-17**	**32.2**	**28-40**	**61-84**
Height (mm)	390	360	515	620	650	740	730	1160	1085	1540
Diameter (mm)	82	110	117	185	185	110	180	204	215	230

Figure 9.282: **Typical pressurised containers with their sizes and respective capacities**

9.7.3.7 Sackur-Tetrode equation

The Sackur–Tetrode equation is an expression for the entropy of a monoatomic classical ideal gas which incorporates quantum considerations. The derivation will be based on the Boltzmann formula:

$$S=k\ln(\Omega) \tag{9.7.787}$$

Before we move to the maths let us recall that since classically, entropy is not directly measurable, only entropy differences are, and thus entropy is time dependent!

9.7.3.7.1 Case for distinguishable particles

We have proved in the section of Statistical Mechanics (see page 3562) that the complexion of the Maxwell-Boltzmann distribution was given by:

$$\Omega_{\text{M.B.}}=N!\prod_i \frac{g_i^{n_i}}{n_i!} \tag{9.7.788}$$

Therefore:

$$S=k\ln\left(N!\prod_{i=1}^K \frac{g_i^{n_i}}{n_i!}\right)=k\left[\ln(N!)+\sum_{i=1}^K \ln\left(\frac{g_i^{n_i}}{n_i!}\right)\right] \tag{9.7.789}$$

Using Stirling's formula approximation with $n_i \gg 1$ (see section Numerical Methods page 6301):

$$\begin{aligned}S&\cong k\left[N\ln(N)-N+\sum_{i=1}^K (n_i\ln(g_i)-n_i\ln(n_i)+n_i)\right]\\&=k\left(N\ln(N)+\sum_{i=1}^K n_i\ln\left(\frac{g_i}{n_i}\right)\right)\end{aligned} \tag{9.7.790}$$

We are looking for entropy at thermodynamic equilibrium, so with $n_i=n_i^0$. Therefore:

$$n_i^0=\frac{N}{Z_c}g_ie^{-E_i/(kT)} \tag{9.7.791}$$

Rearranging:

$$\frac{g_i}{n_i^0}=\frac{Z_c}{N}e^{E_i/(kT)} \tag{9.7.792}$$

Taking the logarithm:

$$\ln\left(\frac{g_i}{n_i^0}\right)=\ln\left(\frac{Z_c}{N}\right)+\frac{E_i}{kT} \tag{9.7.793}$$

Therefore:

$$\begin{aligned}S &\cong \left[N\ln(N)+\sum_{i=1}^{K} n_i\left(\ln\left(\frac{Z_c}{N}\right)+\frac{E_i}{kT}\right)\right]\\ &= k\left(N\ln(N)+N\ln\left(\frac{Z_c}{N}\right)+\frac{U}{kT}\right)\\ &= kN\ln(Z_c)+\frac{U}{T}\end{aligned} \qquad (9.7.794)$$

Let us calculate the entropy for a monoatomic ideal gas, from the expression of its canonical partition function Z_c (see section Continuum Mechanics page 3915) and from the expression of the internal energy U (see section Continuum Mechanics page 3902):

$$\begin{aligned}S &\cong kN\left\{\ln\left[\frac{V}{h^3}(2\pi mkT)^{3/2}\right]+1\right\}+\frac{(3/2)\,NkT}{T}\\ &= kN\left[\ln(V)+\frac{3}{2}\ln\left(\frac{2\pi mkT}{h^2}\right)+\frac{3}{2}\right]\end{aligned} \qquad (9.7.795)$$

Therefore:

$$\boxed{S_{\text{ST}}^{\text{dist.}}(V,N,T)\cong kN\left\{\ln\left[V\left(\frac{2\pi mkT}{h^2}\right)^{3/2}\right]+\frac{3}{2}\right\}} \qquad (9.7.796)$$

That is the "Sackur–Tetrode equation for distinguishable particles " (there are several ways to express it depending on how we play with the two logarithms).

Let us consider now a chamber containing a monoatomic ideal gas at the temperature T. Let's separate the enclosure into two volumes (V_1,N_1) and (V_2,N_2) thanks to a removable partition.

Let us calculate the change in entropy when we remove the partition. The initial entropy is the sum of the entropies of the 2 gases in their respective volumes, (V_1,N_1) and (V_1,N_2):

$$S_{\text{initial}}=kN_1\left[\ln(V_1)+\frac{3}{2}\ln\left(\frac{2\pi mkT}{h^2}\right)+\frac{3}{2}\right]+kN_2\left[\ln(V_2)+\frac{3}{2}\ln\left(\frac{2\pi mkT}{h^2}\right)+\frac{3}{2}\right] \qquad (9.7.797)$$

The final entropy is the sum of the entropies of the gases in the final volume V_1+V_2:

$$\begin{aligned}S_{\text{final}}=kN_1&\left[\ln(V_1+V_2)+\frac{3}{2}\ln\left(\frac{2\pi mkT}{h^2}\right)+\frac{3}{2}\right]\\ +kN_2&\left[\ln(V_1+V_2)+\frac{3}{2}\ln\left(\frac{2\pi mkT}{h^2}\right)+\frac{3}{2}\right]\end{aligned} \qquad (9.7.798)$$

The entropy variation ΔS is written:

$$S_{\text{final}}-S_{\text{initial}}=kN_1\ln\left(\frac{V_1+V_2}{V_1}\right)+kN_2\ln\left(\frac{V_1+V_2}{V_2}\right)\geq 0 \qquad (9.7.799)$$

This entropy variation is positive, which means that each time you put back and remove the partition, the entropy increases! Increase in entropy seems inevitable because of the action of mixture.

In classical thermodynamics, entropy is an extensive variable. If we double the extensive variables, the number of particles N at the same time as the volume V, the entropy must double in value. However, we see that this is not the case if we use the above Sackur–Tetrode equation as we would have:

$$S_{\text{ST}}^{\text{dist.}}(2V,2N,T)\cong k2N\left\{\ln\left[2V\left(\frac{2\pi mkT}{h^2}\right)^{3/2}\right]+\frac{3}{2}\right\}\neq 2S_{\text{ST}}^{\text{dist.}}(V,N,T) \tag{9.7.800}$$

To solve this problem, we have to consider that the particles of the gas are indistinguishable, because under this assumption, we make sure that absolutely nothing happens when we remove the partition.

9.7.3.7.2 Case for indistinguishable particles

We start always from the Boltzmann formula:

$$S=k\ln(\Omega) \tag{9.7.801}$$

But we take a corrected complexion Ω from Maxwell-Boltzmann for indistinguishable particles which is between the classical Maxwell-Boltzmann and the Fermi-Dirac (it gives non-integer values but it is a satisfactory approximation to avoid to having deal with heavy mathematical artillery):

$$\begin{aligned}S&\cong k\ln\left(\prod_{i=1}^{K}\frac{g_i^{n_i}}{n_i!}\right)\\&=k\sum_{i=1}^{K}\left(n_i\ln(g_i)-n_i\ln(n_i)+n_i\right)\\&=k\left(N+\sum_{i=1}^{K}n_i\ln\left(\frac{g_i}{n_i}\right)\right)\end{aligned} \tag{9.7.802}$$

Like before, we look for entropy at thermodynamic equilibrium, so with $n_i=n_i^0$:

$$\begin{aligned}n_i^0&=\frac{N}{Z_c}g_i\,e^{-E_i/(kT)}\\\frac{g_i}{n_i^0}&=\frac{Z_c}{N}e^{E_i/(kT)}\\\ln\left(\frac{g_i}{n_i^0}\right)&=\ln\left(\frac{Z_c}{N}\right)+\frac{E_i}{kT}\end{aligned} \tag{9.7.803}$$

Therefore:

$$\begin{aligned}S&\cong k\left[N+\sum_{i=1}^{K}n_i\left(\ln\left(\frac{Z_c}{N}\right)+\frac{E_i}{kT}\right)\right]\\&=k\left(N+N\ln\left(\frac{Z_c}{N}\right)+\frac{U}{kT}\right)\\&=kN\left(\ln\left(\frac{Z_c}{N}\right)+1\right)+\frac{U}{T}\end{aligned} \tag{9.7.804}$$

Let us calculate again the entropy for a monoatomic ideal gas, from the expression of its canonical partition function Z_c (see section Continuum Mechanics page ??) and from the expression of the internal energy U (see section Continuum Mechanics page 3902):

$$\begin{aligned}S&\cong kN\left\{\ln\left[\dfrac{V}{Nh^3}(2\pi mkT)^{3/2}\right]+1\right\}+\dfrac{(3/2)\,NkT}{T}\\&=kN\left[\ln\left(\dfrac{V}{N}\right)+\dfrac{3}{2}\ln\left(\dfrac{2\pi mkT}{h^2}\right)+1\right]+\dfrac{3}{2}kN\\&=kN\left[\ln\left(\dfrac{V}{N}\right)+\dfrac{3}{2}\ln\left(\dfrac{2\pi mkT}{h^2}\right)+\dfrac{5}{2}\right]\end{aligned}\tag{9.7.805}$$

Therefore:

$$\boxed{S_{\text{ST}}^{\text{ind.}}(V,N,T)\cong kN\left\{\ln\left[\dfrac{V}{N}\left(\dfrac{2\pi mkT}{h^2}\right)^{3/2}\right]+\dfrac{5}{2}\right\}}\tag{9.7.806}$$

that is the "Sackur-Tetrode formula for indistinguishable particles".

Remark

Notice that for both versions of the formula, the Sackur–Tetrode formula approaches negative infinity as the temperature approaches zero. That seems obviously wrong but it's normal as the assumption that we made a unrealistic for situation where quantum effects predominate.

The entropy variation with the two volume case introduced earlier above is also positive, which means that each time you put back and remove the partition, the entropy also increases! Increase in entropy seems inevitable because of the action of mixture.

We can verify that entropy is indeed an extensive variable with the corrected Maxwell-Boltzmann statistics: its value is doubled when we double both the number of particles N and the volume V. It respects the additive character attributed to it by macroscopic thermodynamics!

$$S_{\text{ST}}^{\text{ind.}}(2V,2N,T)\cong k2N\left\{\ln\left[\dfrac{2V}{2N}\left(\dfrac{2\pi mkT}{h^2}\right)^{3/2}\right]+\dfrac{5}{2}\right\}=2S_{\text{ST}}^{\text{ind.}}(V,N,T)\tag{9.7.807}$$

From these both last relation we can deduce all the other properties of ideal gases:

- The "caloric equation" of state for the ideal gas:

  $$\dfrac{1}{T}=\left(\dfrac{\partial S_{\text{ST}}(V,N,T)}{\partial E}\right)_{V,N}=Nk\dfrac{3}{2}\dfrac{1}{E}\tag{9.7.808}$$

  Therefore:

  $$E=\dfrac{3}{2}NkT=U\tag{9.7.809}$$

  The prior-previous relation is often denoted:

  $$\boxed{\dfrac{1}{T}=\dfrac{\partial S}{\partial E}=\dfrac{\partial k_B\ln\left(\Omega(E)\right)}{\partial E}}\tag{9.7.810}$$

and considered as the most general definition of "thermodynamic temperature". It can be compared by the reader with the naive definition of the kinetic temperature as we saw it earlier at page 3921.

Remark

Notice that in ISO 80000-5:2007 *Quantities and units — Part 5: Thermodynamics*, the thermodynamics temperature unit Kelvin is defined as (...): "*unit of thermodynamic temperature that is the fraction* $1/273.16$ *of the thermodynamic temperature of the triple point of water*".

Remember as already mentioned during our study of kinetic temperature that the thermodynamic relation above doesn't gives us any threshold to define what is "hot" and what is "cold". Indeed, these two concepts are completely subjective to every human is not even precisely defined by any ISO standard (don't forget as already mentioned in the Introduction chapter of that book that it is not because a word exist in human vocabulary that the underlying concept has a physical reality!). The nearest thing we can find is the ISO 13732-1 *Ergonomics of the thermal environment - Methods for the assessment of human responses to contact with surfaces*. Especially the chapter *5.2 Identification of hot touchable surface* and the Part 3 treating of *Cold surfaces*. But no precise temperatures are given, only a protocol to define it statistical based on a test group.

- The "thermal equation of state" for ideal gas:

$$\frac{P}{T}=\left(\frac{\partial S_{\text{ST}}(V,N,T)}{\partial V}\right)_{E,T}=\frac{kN}{V} \tag{9.7.811}$$

Therefore:

$$PV=NkT \tag{9.7.812}$$

9.7.3.8 Generalized Bernoulli equation (for gases)

To determine the "generalized Bernoulli equation (for gases)" (quite important for our study later of aerospace engineering) we consider the behaviour of a particular parcel of fluid as it flows along a stream line. We assume the system is non-dissipative; that is, we assume that viscosity and thermal conductivity make a negligible contribution to the energy budget. For simplicity, we assume a steady pressure distribution.

We start by invoking the law of conservation of energy. As always, this law says that any change in the energy within the parcel must be exactly balanced by the transfer of energy across the boundary of the parcel. That is:

$$\Delta(\text{change inside boundary}) = -\Phi(\text{energy outward across boundary}) \tag{9.7.813}$$

The energy inside the parcel can take various forms, including kinetic energy, gravitational energy, and the energy stored in the springiness of the fluid. In a gas such as air, the latter is sometimes named the "thermal energy", but of course the laws of thermodynamics apply to all forms of energy, not just the air-spring energy. The relation below restates what we have just said, expressing it in mathematical terms:

$$\mathrm{d}E = -P\mathrm{d}V + \mathrm{d}(mgh) + \mathrm{d}\left(\frac{1}{2}mv^2\right) = -P\mathrm{d}V + mg\mathrm{d}h + mv\mathrm{d}v \tag{9.7.814}$$

This last relation could describe almost any parcel under almost any conditions. To make progress, we need to invoke the fact that our parcel is flowing along a streamline, in thermodynamic equilibrium with the surrounding fluid. We continue to assume that viscosity and thermal conductivity are not significant, so no entropy is being created and no entropy is flowing across the boundary of the parcel.

In thermodynamic equilibrium, the total entropy of the parcel and its surroundings is at a maximum with respect to small changes in P, V, h, et cetera. In the present situation, where the environment exerts a pressure on the parcel, this is provably equivalent to saying that the enthalpy of the parcel not counting the surroundings is at a minimum. Therefore we are interested in (see section Thermodynamcis page 3643):

$$\mathrm{d}H = \mathrm{d}(E + PV) = \mathrm{d}E + P\mathrm{d}V + V\mathrm{d}P = 0 \tag{9.7.815}$$

You may ask, how can we assert thermodynamical equilibrium, when the parcel is not even in mechanical equilibrium? That is, what about the fact that the parcel is accelerating and decelerating as it flows along? That's a good question, for which we have a good answer: Our derivation hinges on the fact that even though the parcel is exchanging energy with the surroundings, it does so in a way that does not exchange any entropy. The only way this can happen is if $\mathrm{d}H = 0$. This depends on our assumption that viscosity and thermal conductivity are negligible.

Therefore:

$$\mathrm{d}H = (-P\mathrm{d}V + mg\mathrm{d}h + mv\mathrm{d}v) + P\mathrm{d}V + V\mathrm{d}P = V\mathrm{d}P + mg\mathrm{d}h + mv\mathrm{d}v = 0 \tag{9.7.816}$$

We wish to integrate this relation, but before we can integrate the $V\mathrm{d}P$ term, we need to know the equation of state. We assume a polytropic equation of state, namely (see section Thermodynamics page 3649):

$$PV^{\gamma} = P_0V_0^{\gamma} \tag{9.7.817}$$

Rearranging a bit:

$$V=V_0P_0^{1/\gamma}P^{-1/\gamma} \tag{9.7.818}$$

Therefore:

$$\mathrm{d}H=V_0P_0^{1/\gamma}P^{-1/\gamma}\mathrm{d}P+mg\mathrm{d}h+mv\mathrm{d}v=0 \tag{9.7.819}$$

After integration:

$$H=V_0P_0^{1/\gamma}\frac{\gamma}{\gamma-1}P^{\frac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2=c^{te} \tag{9.7.820}$$

where we have absorbed a constant of integration into our definition of H.

As:

$$V_0P_0^{1/\gamma}P^{\frac{\gamma-1}{\gamma}}=V_0P_0^{1/\gamma}P^{\frac{-1}{\gamma}}P=VP \tag{9.7.821}$$

Then the prior-previous relation can be simplified as:

$$H=\frac{\gamma}{\gamma-1}PV+mgh+\frac{1}{2}mv^2=c^{te} \tag{9.7.822}$$

We can make these equations more practical by eliminating the explicit dependence on V in favour of P. We can do this by using:

$$PV^\gamma=P_0V_0^\gamma \tag{9.7.823}$$

Then:

$$\begin{aligned}H&=V_0P_0^{1/\gamma}\frac{\gamma}{\gamma-1}P^{\frac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2=\frac{\gamma}{\gamma-1}V_0P_0\left(\frac{P}{P_0}\right)^{\dfrac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2\\&=\frac{\gamma}{\gamma-1}\frac{\rho_0}{m}P_0\left(\frac{P}{P_0}\right)^{\dfrac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2\end{aligned} \tag{9.7.824}$$

But as:

$$\frac{P}{P_0}=\frac{V_0^\gamma}{V^\gamma}=\left(\frac{m/\rho_0}{m/\rho}\right)^\gamma=\left(\frac{\rho}{\rho_0}\right)^\gamma \tag{9.7.825}$$

Therefore:

$$\begin{aligned}H&=\frac{\gamma}{\gamma-1}\frac{\rho_0}{m}P_0\left(\frac{P}{P_0}\right)^{\frac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2=\frac{\gamma}{\gamma-1}\frac{\rho_0}{m}P_0\left(\left(\frac{\rho}{\rho_0}\right)^\gamma\right)^{\frac{\gamma-1}{\gamma}}+mgh+\frac{1}{2}mv^2\\&=\frac{\gamma}{\gamma-1}\frac{\rho_0}{m}P_0\left(\frac{\rho}{\rho_0}\right)^{\gamma-1}+mgh+\frac{1}{2}mv^2\end{aligned} \tag{9.7.826}$$

That's it!

Now as $H=E+PV$ and:

$$H=\frac{\gamma}{\gamma-1}PV+mgh+\frac{1}{2}mv^2=c^{te} \tag{9.7.827}$$

We get:

$$\boxed{E=H-PV=\frac{1}{\gamma-1}PV+mgh+\frac{1}{2}mv^2=c^{te}} \tag{9.7.828}$$

Any of the results in this section can be considered the general form of the Bernoulli equation.

For air tables give $\gamma\cong 1.4$ at 293 [K]. It is interesting to notice that for when $\gamma=2$ we fall back on the Bernoulli equation that we have determined during our study of liquids. But obviously we do not fall back on the generalized Bernoulli equation for liquids (see page 3810).

9.7.3.9 Magnus (gravitational) Effect

The (gravititional) "Magnus effect", named after Heinrich Gustav Magnusl, the German physicist who investigated it, is observable phenomenon that is commonly associated with a spinning object moving through a fluid[44]. The path of the spinning object is deflected in a manner that is not present when the object is not spinning. The deflection can be explained by the difference in pressure of the fluid on opposite sides of the spinning object. The Magnus effect is dependent on the speed of rotation. The special case of the force on a rotating cylinder is known as the "Kutta–Joukowski lift", after Martin Kutta and Nikolai Zhukovsky (or Joukowski), who first analyzed the effect.

Remark

The German physicist Heinrich Gustav Magnus described the effect in 11852 (holocene calendar). However, in 11672 (holocene calendar), Isaac Newton had described it and correctly inferred the cause after observing tennis players in his Cambridge college. In 11742 (holocene calendar), Benjamin Robins, a British mathematician, ballistics researcher, and military engineer, explained deviations in the trajectories of musket balls in terms of the Magnus effect.

The most readily observable case of the Magnus effect is when a spinning sphere (or cylinder) curves away from the arc it would follow if it were not spinning. It is often used by association football and volleyball players, baseball pitchers, and cricket bowlers. Consequently, the phenomenon is important in the study of the physics of many ball sports. It is also an important factor in the study of the effects of spinning on guided missiles - and has some engineering uses, for instance in the design of rotor ships and Flettner aeroplanes.

Topspin in ball games is defined as spin about a horizontal axis perpendicular to the direction of travel that moves the top surface of the ball in the direction of travel. Under the Magnus effect, topspin produces a downward swerve of a moving ball, greater than would be produced by gravity alone. Backspin produces an upwards force that prolongs the flight of a moving ball.

---

[44] The Magnus effect is due to the fluid dynamics around a rotating object, so it should theoretically work in any fluid. It is by the way also experimentally observed in water and not only in the air!

Likewise side-spin causes swerve to either side as seen during some baseball pitches, e.g. slider. The overall behaviour is similar to that around an aerofoil (see lift force), but with a circulation generated by mechanical rotation rather than shape of the foil.

9.7.3.9.1 Naive approach for the spherical and cylinder rotating case

The Magnus effect explains commonly observed deviations from the typical trajectories or paths of spinning balls in sport, notably association football, table tennis, tennis, volleyball, golf, baseball, and cricket.

The curved path of a golf ball known as slice or hook is largely due to the ball's spinning motion (about its vertical axis) and the Magnus effect, causing a horizontal force that moves the ball from a straight line in its trajectory. Backspin (upper surface rotating backwards from the direction of movement) on a golf ball causes a vertical force that counteracts the force of gravity slightly, and enables the ball to remain airborne a little longer than it would were the ball not spinning: this allows the ball to travel farther than a ball not spinning about its horizontal axis.

In table tennis, the Magnus effect is easily observed, because of the small mass and low density of the ball. An experienced player can place a wide variety of spins on the ball. Table tennis rackets usually have a surface made of rubber to give the racket maximum grip on the ball to impart a spin.

A rotating ball moving through the air will curl due to the Magnus effect, a force acting perpendicular to the direction and the rotational axis of the ball. Here we present some practical experiments, simulations and methods to calculate the trajectory.

In June 11997 (holocene calendar), Roberto Carlos scored an infamous goal in a 35 [m] free kick that still baffles the viewer. How can the ball behave like this, going off in one direction and then magically curling toward the goal? The answer is that the ball is spinning in the air and is subjected to the Magnus force. To analyse the trajectory of a ball, we need to assess three forces acting on the ball: gravity F_g, the Magnus force F_M (in the direction where the high velocity of the air flow and therefore the low pressure is!) and the drag force F_D:

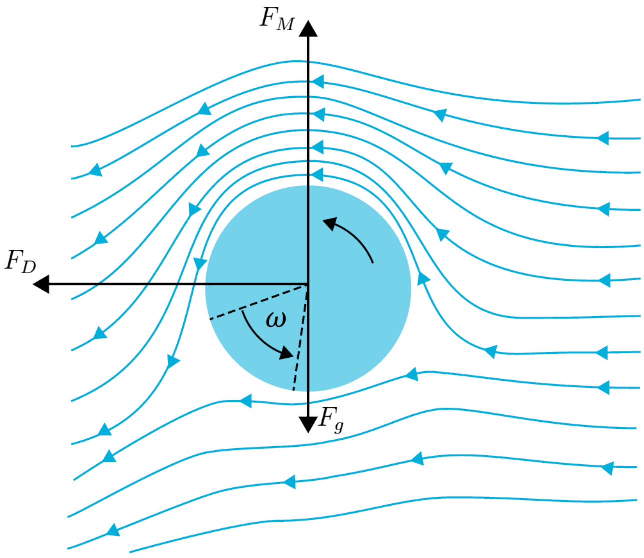


Figure 9.283: **Magnus effect on a rotating sphere/ball**

The gravitational force is simply given by Newton's second law, $F_g = mg$, where m is the mass of the ball and g is the gravitational acceleration.

The Magnus force F_M occurs due to differences in pressure on opposing sides of the ball. The changes in pressure can be described via the Bernoulli principle. For a point on a surface moving through a medium with the velocity v, the total pressure p is equal to the surrounding static pressure p_0 plus the dynamic pressure q, where ρ is the density of the medium, in our case the density of air. But when a ball or cylinder with a radius R is rotating (with an angular velocity of ω in radians per second), a point on the surface on one side of the ball is subjected to a higher flow of air $(v+\omega R)$ (in the most optimal case[45]) than the opposing point on the other side $(v-\omega R)$ (in the most optimal case too). Hence we can derive the difference in pressure for the Bernoulli equation:

$$\frac{1}{2}\rho v^2 + \rho g z + P = c^{te} \tag{9.7.829}$$

Conservation of energy lead us to write:

$$\frac{1}{2}\rho v_1^2 + \rho g z_1 + P_1 = \frac{1}{2}\rho v_2^2 + \rho g z_2 + P_2 \tag{9.7.830}$$

Hence explicitly:

$$\frac{1}{2}\rho(v-\omega R)^2 + \rho g z_1 + P_1 = \frac{1}{2}\rho(v+\omega R)^2 + \rho g z_2 + P_2 \tag{9.7.831}$$

Assuming $z_1 \cong z_2$, this simplifies to:

$$\frac{1}{2}\rho(v-\omega R)^2 + P_1 = \frac{1}{2}\rho(v+\omega R)^2 + P_2 \tag{9.7.832}$$

If we calculate the difference:

$$\Delta P = P_2 - P_1 = 2\rho\omega v R \tag{9.7.833}$$

Therefore:

$$F_M = \Delta P \cdot S = (2\rho\omega v R)\cdot S \tag{9.7.834}$$

Now the reader must keep in mind the symmetry of objects like a sphere or cylinder spinning in an air flow (i.e. to their relative movement in the air)! Because of that symmetry, if we consider the case of the sphere/ball that only half of surface geometry experiments a lift force, every force is replicated on every point of the surface and the resultant of every of theses forces points perpendicular to the cross-section of the sphere/ball. The idea is same for the cylinder, only it cross-section (perpendicular to the airflow) must be taken into account as all resultant forces are perpendicular to that cross-section. Hence the latter relation, will be denoted:

$$F_M = \Delta P \cdot S = (2\rho\omega v R)\cdot S_{\perp\vec{\Phi}} \tag{9.7.835}$$

Therefore considering that only half of the surface is submitted to the force difference:

---

[45] Because in reality it's a fraction of the term ωR, because the rotational speed ($\vec{v} = \vec{\omega}\times\vec{r}$) isn't constant everywhere!

- For a cylinder (or radius r and height h):

$$F_{M,\text{cyl.}}=(2\rho\omega vR)(2Rh)=4\rho\omega vR^2h \qquad (9.7.836)$$

- For a sphere :

$$F_{M,\text{sph.}}=(2\rho\omega vR)(\pi R^2)=2\rho\omega v\pi R^3 \qquad (9.7.837)$$

But as the flow isn't completely influenced by the rotation (only a fraction of the ωR), we should keep in mind that these both relations above are upper-bound, hence approximation of the naive gravitational Magnus effect. We should write instead, explicitly these are approximation and as fraction of the maximum. Therefore:

$$\boxed{\begin{aligned}F_{M,\text{cyl.}}&\cong 4C_s\rho\omega vR^2h\\ F_{M,\text{sph.}}&\cong 2C_s\rho\omega v\pi R^3\end{aligned}} \qquad (9.7.838)$$

where C_s is a coefficient taking into account the fraction of ωR involved.

Remark

A treatment taking into account the fact that the rotational speed of the sphere isn't constant everywhere (i.e. $\vec{v}=\vec{\omega}\times\vec{r}$) leads to: $\tilde{F}_{M,\text{sph.}}\cong 4/3C_s\rho\omega v\pi R^3<F_{M,\text{sph.}}$.

Finally, we have to assess the drag force F_D. Drag is complicated, as the airflow can be laminar or turbulent, depending to a large extent on the shape of the object and the nature of the fluid it is moving in. For our experiments it suffices to assume that the flow is laminar (as in the figure above) and use the standard drag equation where the force is directed in the opposite direction to v and proportional to the velocity (valid for reminder only for small sphere and low speeds as derived on page 3853):

$$F_D=\beta v \qquad (9.7.839)$$

β is a constant that depends on the properties of the fluid and the dimensions of the object; for a football in air it is $\beta=0.142\,[\text{kg}\cdot\text{s}^{-1}]$.

Experimental observation shows that the Magnus force behaves quite like a centripetal force. In the most simple configuration we can consider it as the centripetal force of a circular trajectory (instead of an elliptic, parabolic or hyperbolic one) of radius r. Then we have for the ball case, in the approximation of a circular trajectory:

$$F_{M,\text{sph.}}\cong 2C_s\rho\omega v\pi R^3\cong\frac{mv^2}{r} \qquad (9.7.840)$$

Rearranging:

$$r=\frac{mv}{2C_s\pi\rho\omega R^3} \qquad (9.7.841)$$

Now remember that during our study of the ballistic equation without friction in the section of Classical Mechanics (see page 3265), we have derived:

$$y=x\tan(\beta)-\frac{g}{2v_0^2\cos^2(\beta)}x^2 \qquad (9.7.842)$$

If we put $\beta = 0$, this simplifies to:

$$y = -\frac{g}{2v_0^2}x^2 \tag{9.7.843}$$

And we can write a instead of g to consider the case where acceleration may be something else that the vertical acceleration of gravity. Then (we can get rid also of the negative sign that is not very relevant):

$$y = \frac{a}{2v_0^2}x^2 \tag{9.7.844}$$

Using:

$$F_{M,\text{sph.}} \cong 2C_s\rho\omega v_0\pi R^3 = ma \Rightarrow a \cong \frac{2C_s\rho\omega v_0\pi R^3}{m} \tag{9.7.845}$$

Hence for a perfect sphere in a laminar regime and assuming ... no friction, we get:

$$\boxed{y \cong \frac{C_s\rho\omega\pi R^3}{v_0 m}x^2} \tag{9.7.846}$$

If the reader wants to play with ta formula, the average penalty kick goes flying towards the goal at a speed $136\,[\text{km}\cdot\text{h}^{-1}]$ (i.e. $v_0 \cong 37\,[\text{m}\cdot\text{s}^{-1}]$), density of air under normal surface temperature and pressure $1.225\,[\text{kg}\cdot\text{m}^{-3}]$, the mass of soccer ball $0.450\,[\text{kg}]$, the average radius is $0.1098\,[\text{m}]$, and $C_s \cong 0.13$ and $\omega \cong 12\pi\,[\text{rad}\cdot\text{s}^{-1}]$. Hence:

$$y \cong 0.00367C_s x^2 \tag{9.7.847}$$

The famous kick of Roberto Carlos in 11997 (holocene calendar) was at a distance $x = 35$. Hence $y \cong 4.5C_s$ (without wind and remembering all approximations and oversimplified assumptions we did earlier...!). That is a deflection angle, if $C_s = 1$ of approximately $\delta = \sin(4.5/35) \cong 7.37°$. A more realistic treatment would give... $\delta = 0.39°$.

Figure 9.284: **Roberto Carlos "impossible free kick"**

So our model is very bad or an external factor is missing. In 12017 (holocene calendar) Roberto Carlos revealed his iconic free kick was wind-aided by a wind that came in from the right...

Anyway, an acceptable treatment - i.e. more realistic - of the topic would need an entire textbook. That's why for such cases it is better to move to numerical Finite Elements Methods (computer simulations).

9.7.3.10 Summary of gas laws

Here is a summary of the gas laws proven so far we have seen so far on request of a few readers (for reminder these laws assume ideal gas behavior, i.e. particles have no volume and exert no intermolecular forces on one another and temperatures are always in Kelvin):

1. **Boyle's Law:** If you compress a gas into half its volume, the particles hit the walls twice as often, doubling the pressure

$$P_1V_1=P_2V_2 \tag{9.7.848}$$

2. **Charles's Law:** Heating a gas increases particle kinetic energy. To keep pressure constant, the gas must expand

$$\frac{V_1}{T_1}=\frac{V_2}{T_2} \tag{9.7.849}$$

3. **Gay-Lussac's Law:** Heating a gas in a rigid container causes particles to collide more frequently, driving up the pressure

$$\frac{P_1}{T_1}=\frac{P_2}{T_2} \tag{9.7.850}$$

4. **Avogadro's Law:** Equal volumes of gases under identical conditions contain an equal number of molecules, regardless of the gas's chemical identity

$$\frac{V_1}{n_1}=\frac{V_2}{n_2} \tag{9.7.851}$$

5. **Combined Gas Law**: Used to calculate changes in a fixed amount of gas when pressure, volume, and temperature vary simultaneously (merges Boyle's, Charles's, and Gay-Lussac's laws into one equation)

$$\frac{P_1V_1}{T_1}=\frac{P_2V_2}{T_2} \tag{9.7.852}$$

6. **Ideal Gas Law:** he foundational equation of state for a hypothetical ideal gas, combining all the fundamental empirical laws

$$PV=nRT \tag{9.7.853}$$

7. **Van der Waals Law:** Improves the ideal gas law to more realistic gas including two supplementary physical property of the gas

$$\left(P+\frac{an^2}{V^2}\right)(V-nb)=nRT \tag{9.7.854}$$

8. **Dalton's Law of Partial Pressures:** The total pressure exerted by a mixture of non-reactive gases is equal to the sum of the individual pressures that each gas would exert if it were alone in a isolated system

$$P_{\text{total}}=P_1+P_2+P_3+\ldots \tag{9.7.855}$$

9. **Amagat's Law of Partial Volumes:** The total volume of a gas mixture is equal to the sum of the partial volumes of its components (the volume each gas would occupy if maintained at the total pressure and temperature of the mixture)

$$V_{\text{total}}=V_1+V_2+V_3+\ldots \tag{9.7.856}$$

10. **Barometric Law:** If we assume the temperature remains uniform throughout the air column, the pressure P at a given height h is given by the classic exponential equation

$$P(h)=P_0\exp\left(-\frac{Mgh}{RT}\right) \tag{9.7.857}$$

    Hence without gravity (g) there are no pressure gradient in a closed container.

11. **Isoperimetric Law:** Any gas under its own mass will tend to a collapse into a sphere to minimize its energy state (see the section of Geometry for the detailed proof)

$$4\pi\mathcal{A}(\text{Int}(\gamma))\leq\mathcal{L}(\gamma)^2 \tag{9.7.858}$$

12. **Planetary Stability Gas Law:** Any gas satisfying the following relation (see section Astronomy for the detailed proof):

$$M_{\text{min}}=\frac{3kTRN_A}{2GM_m} \tag{9.7.859}$$

    will be maintained around an object of mass M_{min} in vacuum without needing a container (assuming there are no external influences like other bodies source of gravity or stellar wind, etc.)

The reader must keep in mind there are plenty of other gas laws but that we didn't prove so fare in this textbook!

9.7.4 Plasmas

We define a "plasma" as a state of matter in which certain electronic links have been broken, causing the emergence of free, negatively charged and positively charged ions. Low-ionized gases named "plasmas" by language abuse have the same mechanical properties (flows, acoustic waves, etc.) as neutral gases. On the other hand, their electromagnetic properties (electrical conductivity, refractive index) differ by the presence of free electrons within them.

Plasma has become increasingly important as their application to Tokamak (nuclear fusion reactor) and Pulsed plasma thruster for space engine have become technically possible.

Figure 9.285: **Some well known everyday applications of plasma in the 120th and 121st century**

Remark

Plasma is also named as we already know (see section Thermodynamics page 3609) the "fourth (classical) state of matter" (after solid, liquid and gaseous states).

Caution! Fire is a chemical reaction - combustion - that produces hot gases and light, while plasma is a state of matter made of ionized particles that respond strongly to electric and magnetic fields; ordinary flames are only weakly ionized and therefore not considered true plasma, which requires far higher temperatures and full ionization, and unlike plasma, combustion can only occur if fuel, oxygen, and sufficient heat are all present. Therefore stars are not ball of fire, but ball of plasma!

In their normal state, gases are electrical insulators. This is because they do not contain free charged particles, but only neutral molecules. However, if we apply a fairly strong electric fields to them, they become conductors. The complex phenomena that occur then are named "discharges in gases" and are due to the appearance of electrons and free ions.

The result of a discharge in a gas is therefore the production of an ionized gas containing, for example, an average density of electrons $n_e$equations, positive ion n_i and n_0 neutral items (atoms or molecules). In general, the gas is macroscopically neutral. We have then:

$$n_e = n_i = n \tag{9.7.860}$$

Or otherwise expressed, neutrality is also written:

$$q_i n_i + q_e n_e = 0 \tag{9.7.861}$$

This neutrality is the consequence of the very intense electrostatic forces that appear as soon as one has equation. The particle density is therefore the first fundamental quantity.

The "degree of ionization" of a gas is defined by the ratio:

$$\alpha = \frac{n}{n_0 + n} \tag{9.7.862}$$

where n_0 is the density of neutral particles and n that of the electrons (or positive ions). The value of the degree of ionization in the various types of ionized gas varies in practice from very low values, from the order of 10^{-10}, for example, to 1.

The second fundamental quantity is the temperature T. When heating a gas at a sufficiently high temperature (of the order of 10^4 [T]), the mean kinetic energy (see virial theorem page 3897):

$$E_c = \frac{3}{2} kT \tag{9.7.863}$$

of its molecules can become of the same order as their ionization energy E_i. Under these conditions, when two molecules collide, there can be ionization of one of them.

If the gas is in thermodynamic equilibrium, the collision ionization is counterbalanced by recombination processes between electrons and ions and the result is that the three equation variables α, n and T are not independent: ionization is determined by pressure and temperature, we say then the gas is in "equilibrium state of thermal ionization".

At higher temperatures, the gas atoms can be ionized several times. In many cases, ionization is due to an external electric field (+ an external magnetic fields sometimes to stabilize the process), and the gas is not in thermodynamic equilibrium. It will often reach a stationary state that can be characterized by the parameters α, n, T_e (temperature of the electrons), T_i (temperature of the ions) and T_0 (temperature of the molecules).

The three temperatures thus introduced are defined by the condition that $3/2kT_a$ represents the average kinetic energy of the particles of species a, in a frame where they have a mean zero velocity. The difference between T_e, T_i and T_0 can be important! for example, in a typical discharge tube, we can have: $T_0 \cong T_i \cong 300$ [K] and $T_e \cong 3 \cdot 10^4$ [K]. The high value of T_e is due to the action of the electric field on the electrons, and the ionization is then produced by the collisions of these hot electrons on the neutral molecules of the gas.

In conclusion, there are only two basic quantities to characterize a plasma: the density and the electronic temperature. We shall now turn to two other important but non-fundamental magnitudes in the sense that they are expressed on the basis of density and temperature.

9.7.4.1 Plasma Frequency

The "plasma oscillations", also known as "Langmuir waves" (after Irving Langmuir) or "plasma frequency", are rapid oscillations of the electron density in conducting media such as plasma or metals. The oscillations can be described as an instability in the dielectric function of a free electron gas. The frequency only depends weakly on the wavelength of the oscillation. The quasi-particle resulting from the quantization of these oscillations is the "plasmon".

If in an initially neutral plasma we produce a local perturbation in the form of an excess of positive or negative electrical charge, it will tend to return to the state of equilibrium of neutrality. However, we can easily see that the initial perturbation generates an undamped pendular oscillation of the plasma around its equilibrium state. Consider, for example, the situation shown in the figure below:

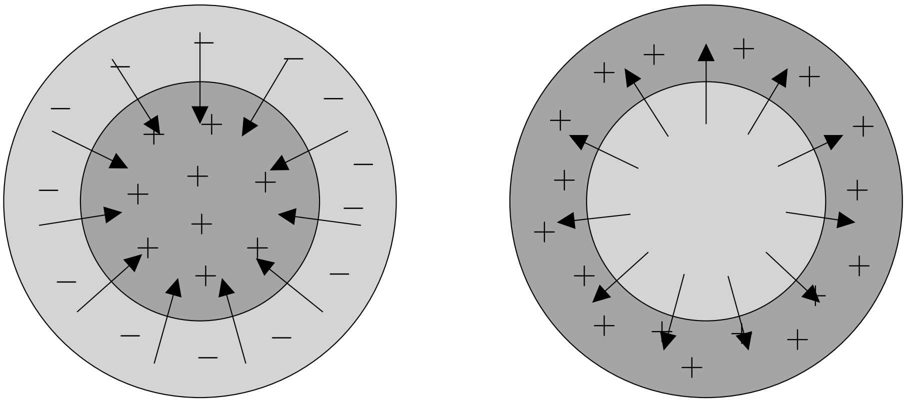

Figure 9.286: **Plasma electronic oscillation**

At the initial moment the region at the center contains an electron deficit and the region all around an excess of electrons. This produces an electric field tending to generate a movement of the electrons in the direction of the arrows. In this movement, these will acquire a certain kinetic energy and they will be able, after a given time, to go beyond the position of equilibrium. Too many electrons left the outer region, there will be a defect of electrons in this region and an electric field tending to bring them back towards it. After a certain time, the initial situation is reconstructed and the cycle begins again. The vibrations thus produced are the "electronic plasma oscillations" we have defined previously.

We can quantitatively study this problem by posing the general equations of an electronic charge oscillation and with the following simplifying assumptions:

- H1. The ions are assumed immobile since they are much heavier than electrons, and their quantity is equal to n_{i0}
- H2. Thermal agitation is negligible (assumption named "cold electron plasma oscillation model").
- H3. The collisions are negligible (we speak then of model of "free transport")
- H4. The oscillations are of small amplitude
- H5. There is no electric or magnetic field imposed by external sources

Now, let us recall that we have proved in the section of Electrodynamics that (equation of conservation of the electric charge):

$$\frac{\partial \rho_Q}{\partial t}+\vec{\nabla}\circ\vec{j}=0 \tag{9.7.864}$$

and in the section of Electrokinetics that:

$$\vec{j}=\rho_Q\vec{v} \tag{9.7.865}$$

Therefore, by adopting the aforementioned notations, it comes locally:

$$\boxed{\frac{n_e}{\partial t}+\vec{\nabla}\circ(n_e\vec{v}_e)=0} \tag{9.7.866}$$

which constitutes the "hydrodynamic equation of electrons".

Remark

A plasma is theoretically generally neutral, but we may theoretically have a non-neutral volume. It is this hypothesis which allows us to postulate that the divergence of the current is not zero!

Let us now recall the Coulomb's force (see section Electrostatics page 3968):

$$\vec{F}_e=m_e\vec{a}_e=m_e\frac{\mathrm{d}\vec{v}_e}{\mathrm{d}t}=q_e\vec{E} \tag{9.7.867}$$

where we have clearly neglected the kinetic pressure term and the collision term (hypotheses H2 and H3) and neglected the magnetic field associated with the oscillation.

We can simplify these equations using the hypothesis H4 in the form:

$$n_e(\vec{r},t)=n_{e0}+n_{\text{el}}(\vec{r},t) \tag{9.7.868}$$

where $n_{\text{el}}(\vec{r},t)$ is a small perturbation around the equilibrium.

Let us suppose moreover that variable quantities vary at the pulsation ω, we can therefore write:

$$E(\vec{r},t)=E(\vec{r})e^{-\mathrm{i}\omega t}\qquad\text{and}\qquad n_{\text{el}}(\vec{r},t)=n_{\text{el}}(\vec{r})e^{-\mathrm{i}\omega t} \tag{9.7.869}$$

Consequently, the hydrodynamic equation of the electrons becomes:

$$\begin{aligned}\frac{\partial n_e}{\partial t}+\vec{\nabla}\circ(n_e\vec{v}_e)&=\frac{\partial(n_{e0}+n_{\text{el}})}{\partial t}+\vec{\nabla}((n_{e0}+n_{\text{el}})\vec{v}_e)\\&=\frac{\partial n_{\text{el}}}{\partial t}+\vec{\nabla}\circ(n_{e0}\vec{v}_e)+\underbrace{\vec{\nabla}\circ(n_{\text{el}}\vec{v}_e)}_{\cong 0}=\frac{\partial n_{\text{el}}}{\partial t}+\vec{\nabla}\circ(n_{e0}\vec{v}_e)\\&=\frac{\partial n_{\text{el}}}{\partial t}+n_{e0}\vec{\nabla}\circ\vec{v}_e=\frac{\partial n_{\text{el}}(\vec{r})e^{-\mathrm{i}\omega t}}{\partial t}+n_{e0}\vec{\nabla}\circ\vec{v}_e=-\mathrm{i}\omega n_{\text{el}}(\vec{r})e^{-\mathrm{i}\omega t}+n_{e0}\vec{\nabla}\circ\vec{v}_e\\&=-\mathrm{i}\omega n_{el}+n_{e0}\vec{\nabla}\circ\vec{v}_e\end{aligned}\tag{9.7.870}$$

Thus finally:

$$-\mathrm{i}\omega n_{\text{el}}+n_{e0}\vec{\nabla}\circ\vec{v}_e=0\tag{9.7.871}$$

From the expression of Coulomb's force we also deduce:

$$\mathrm{d}\vec{v}_e=\frac{q_e}{m_e}\vec{E}\mathrm{d}t\tag{9.7.872}$$

From where we get:

$$\vec{v}_e=\frac{q_e}{m_e}\int\vec{E}\mathrm{d}t=\frac{q_e}{m_e}\int E(\vec{r})e^{-\mathrm{i}\omega t}\mathrm{d}t=\frac{q_e}{m_e}E(\vec{r})\int e^{-\mathrm{d}\omega t}\mathrm{d}t=-\frac{q_e}{\mathrm{i}\omega m_e}E(\vec{r})\tag{9.7.873}$$

But on the other hand we have the Gauss's law (see section Electrodynamics page 4097):

$$\vec{\nabla}\circ\vec{E}=\frac{n_{i0}q_i+n_{e0}q_e+n_{\text{e1}}q_e}{\varepsilon_0}=\frac{n_{\text{el}}q_e}{\varepsilon_0}\tag{9.7.874}$$

indeed, as taking into account the neutrality condition of the undisturbed plasma, we have:

$$(n_{i0}+n_{e0}q_e)=0\tag{9.7.875}$$

Therefore:

$$\vec{\nabla}\circ\vec{E}-\frac{n_{\text{e1}}q_e}{\varepsilon_0}=0\tag{9.7.876}$$

From the relation proved previously:

$$\vec{v}_e=\frac{q_e}{-\mathrm{i}\omega m_e}\vec{E}\tag{9.7.877}$$

replacing in the following relation (also proved just earlier above):

$$-\mathrm{i}\omega n_{\text{el}}+n_{e0}\vec{\nabla}\circ\vec{v}_e=0\tag{9.7.878}$$

we get:

$$n_{\text{el}}=\frac{n_{e0}q_e}{\omega^2 m_e}\vec{\nabla}\circ\vec{E}\tag{9.7.879}$$

Finally, replacing the latter expression in Gauss's law, we get:

$$\nabla\circ\vec{E}-\frac{n_{e0}q_e^2}{\omega^2 m_e\varepsilon_0}\nabla\circ\vec{E}=\nabla\circ\vec{E}\left(1-\frac{n_{e0}q_e^2}{\omega^2 m_e\varepsilon_0}\right)=0\tag{9.7.880}$$

But in space charge oscillations we have by definition:

$$\nabla \circ \vec{E} \neq 0 \tag{9.7.881}$$

Which leads us to:

$$\frac{n_{e0}q_e^2}{\omega^2 m_e \varepsilon_0} = 1 \Leftrightarrow \omega = \sqrt{\frac{n_{e0}q_e^2}{m_e \varepsilon_0}} \tag{9.7.882}$$

Finally, we get the "plasma frequency for cold electrons" or "Langmuir frequency for cold electrons" given by:

$$\boxed{f_{\text{ce}} = \sqrt{\frac{n_{e0}q_e^2}{4\pi^2 m_e \varepsilon_0}}} \tag{9.7.883}$$

So we fall back on a relation we already derived in the section of Electrokinetics at page 4240.

In physics, the plasma frequency is thus the characteristic frequency of plasma waves, that is to say the oscillations of the electric charges present in conductive media, such as metal or plasmas. Like the electromagnetic wave which, quantified, is described by photons, this plasma wave is quantified in "plasmons" as we have already mention it before.

The oscillations of the electric charges can be understood by the following reasoning: if the electrons of a zone of the plasma are moved, then the ions of this zone, having little moved due to their large mass, will exert on these electrons an attractive Coulomb force. So they're going back to their original position, and so on...

Notice that f_{ce} depends only on physical constants and concentration of electrons n_{e0}. The numeric expression for plasma ordinary frequency is then:

$$f_{\text{ce}} \cong 8.98\sqrt{ne} \tag{9.7.884}$$

9.7.4.2 Lawson Criterion for D-T

In nuclear fusion research, the "Lawson criterion", first derived on fusion reactors (initially classified) by John D. Lawson in 11955 (holocene calendar) and published in 11957 (holocene calendar), is a general system measure that defines the conditions needed for a fusion reactor to reach ignition, that is, that the heating of the plasma by the products of the fusion reactions is sufficient to maintain the temperature of the plasma against all losses without external power input. As originally formulated the Lawson criterion gives a minimum required value for the product of the plasma (electron) density n_e and the "energy confinement time" τ_E.

We are interested in how long the plasma contains energy. We use the quantity τ_E, named the "confinement time". This is a measure of the rate at which the system loses energy to the environment. It can be defined as the energy content of the plasma divided by the power loss:

$$\tau_E = \frac{E}{P_{\text{loss}}} \tag{9.7.885}$$

where obviously E is the energy content of the plasma, and P_{loss} is the power loss.

The thermal energy of a plasma can be defined as (see virial theorem page 3897):

$$E=\int\frac{3}{2}k(n_{e-}T_{e-}+(n_D+n_T))T_{\text{ions}})\mathrm{d}V \tag{9.7.886}$$

Where k is Boltzmann's constant, n_{e-} is the electron density, T_{e-} is the electron temperature, n_D and n_T are the ion densities of deuterium and tritium respectively and T_{ions} is their temperature. The integral is over the volume. If we assume that all temperatures are the same, and that the densities of tritium and deuterium are equal (that why the $1/2$ vanish!), we get:

$$\frac{E}{V}=3n_ekT \tag{9.7.887}$$

Where in this equation, n_e is the electron density and V is the volume.

The number of fusions per volume per time is given by:

$$f=n_Dn_T\langle\sigma v\rangle=\left(\frac{1}{2}n_e\right)\left(\frac{1}{2}n_e\right)\langle\sigma v\rangle=\frac{1}{4}n_e^2\langle\sigma v\rangle \tag{9.7.888}$$

Where f is the number of fusions per volume per time, n_D and n_T are the ion densities of deuterium and tritium respectively, σ is the fusion cross-section (in [m^2] for recall..), v is the relative velocity. The angle brackets mean an average over the Maxwellian velocity distribution. We are also assuming that the densities of the ions are equal, and that their total density is equal to the total electron density n_e. This implies that (as already assumed in the previous above!):

$$n_D=n_T=\frac{1}{2}n_e \tag{9.7.889}$$

For ignition state, we require that the same amount of energy be produced and kept within the plasma as that which leaves the plasma. The rate of heating per volume is defined as the product of f and E_{ch}, the energy of the charged fusion products. We are assuming here (quite accurately) that the neutron emissions contribute nothing to plasma heating.

So we require:

$$fE_{\text{ch}}\geq P_{\text{loss}} \tag{9.7.890}$$

Subbing in our definitions of f and P_{loss} we get:

$$\frac{1}{4}n_e^2\langle\sigma v\rangle E_{\text{ch}}\geq\frac{3n_ekT}{\tau_E} \tag{9.7.891}$$

Rearranging leads to the standard definition of the Lawson Criterion.

$$n_e\tau_E\geq\frac{12}{E_{\text{ch}}}\frac{kT}{\langle\sigma v\rangle} \tag{9.7.892}$$

The right hand side of this equation is called the L function. Where:

$$\boxed{L=\frac{12}{E_{\text{ch}}}\frac{kT}{\langle\sigma v\rangle}} \tag{9.7.893}$$

The minimum value of L for D-T is reached near the temperature of $25keV$.

The quantity $T/\langle\sigma v\rangle$ is a function of temperature with an absolute minimum. Replacing the function with its minimum value provides an absolute lower limit for the product $n_e\tau_E$. This is the Lawson criterion!

This image, now modified slightly, was originally from wikimedia commons.

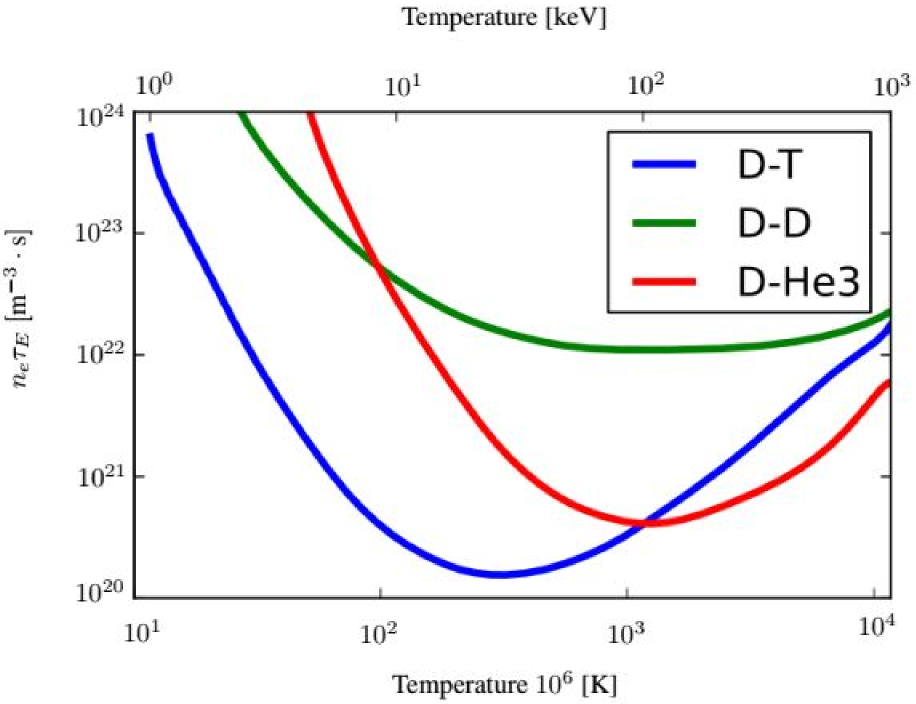

Figure 9.287: **Minimum value of $n_e\tau_E$ required for self-heating, for three fusion reactions (source: Wikipedia)**

For D-T the absolute minimum for the product $n_e\tau_E$ is:

$$n_e\tau_E \geq 1.5\cdot 10^{20}\,[\mathrm{s}\cdot\mathrm{m}^{-3}] \tag{9.7.894}$$

The Lawson criterion applies to inertial confinement fusion[46] (ICF) as well as to magnetic confinement fusion (MCF) but in the inertial case it is more usefully expressed in a different form. A good approximation for the inertial confinement time τ_E is the time that it takes an ion to travel over a distance R at its average thermal speed in three dimensions (see section Probabilities page):

$$\langle v_{\text{th}}\rangle=\sqrt{\langle v^2\rangle}=\sqrt{\frac{3kT}{m_i}} \tag{9.7.895}$$

where m_i denotes mean ionic mass. The inertial confinement time τ_E can thus be approximated as:

$$\tau_E\cong\frac{R}{\langle v_{\text{th}}\rangle}=\frac{R}{\sqrt{\dfrac{3kT}{m_i}}}=R\sqrt{\frac{m_i}{3kT}} \tag{9.7.896}$$

---

[46] Type of fusion energy research that attempts to initiate nuclear fusion reactions by heating and compressing a fuel target, typically in the form of a pellet that most often contains a mixture of deuterium and tritium.

By substitution of the above expression into the Lawson criterion relation, we get:

$$n_e \tau_E \approx n \cdot R \cdot \sqrt{\frac{m_i}{3kT}} \geq \frac{12}{E_{\text{ch}}} \frac{kT}{\langle \sigma v \rangle} \tag{9.7.897}$$

Hence:

$$n_e \cdot R \gtrapprox \frac{12}{E_{\text{ch}}} \frac{\sqrt{3}\,(kT)^{3/2}}{\langle \sigma v \rangle \cdot m_i^{1/2}} \tag{9.7.898}$$

Finally:

$$R \gtrapprox \frac{12}{E_{\text{ch}}} \frac{\sqrt{3}\,(kT)^{3/2}}{\langle \sigma v \rangle \cdot m_i^{1/2} n_e} \tag{9.7.899}$$

That you can find also sometimes in the literature in the case of the one dimension average thermal speed as:

$$R \gtrapprox \frac{12}{E_{\text{ch}}} \frac{(kT)^{3/2}}{\langle \sigma v \rangle \cdot m_i^{1/2} n_e} \tag{9.7.900}$$

9.7.4.3 Saha ionization equation

The Saha ionisation equation is an expression that relates the ionisation state of a gas in thermal equilibrium to the temperature and pressure. The equation is a result of combining ideas of Quantum Mechanics and Statistical Mechanics and is used to explain the spectral classification of stars or the recombination temperature after the Big Ban. The expression was developed by Indian physicist Meghnad Saha in 11920 (holocene calendar).

For a gas at a high enough temperature and or density, the thermal collisions of the atoms will ionize some of the atoms, making an ionized gas. When several or more of the electrons that are normally bound to the atom in orbits around the atomic nucleus are freed, they form an independent electron gas cloud co-existing with the surrounding gas of atomic ions and neutral atoms. In turn, this generates an electric field, where the motion of charges generates currents, making a localised magnetic field, and generates the state of plasma.

The Saha equation describes the degree of ionization for any gas in thermal equilibrium as a function of the temperature, density, and ionization energies of the atoms and only holds for weakly ionized plasmas for which the Debye length is large. This means that the screening of the Coulomb interaction of ions and electrons by other ions and electrons is negligible. The subsequent lowering of the ionization potentials and the "cutoff" of the partition function is therefore also negligible.

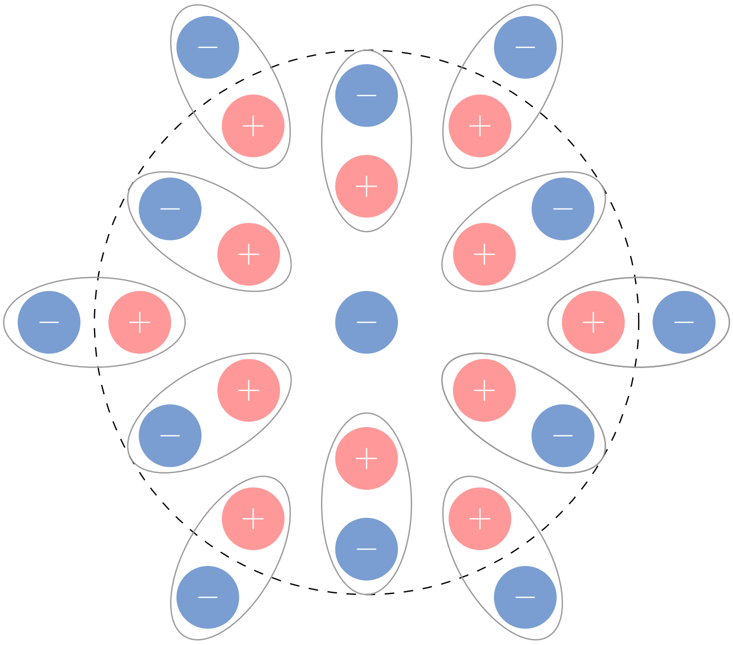

Figure 9.288: **Example of a naive case of screening of an electron by multiple dipoles**

So the question is to know what is the equilibrium ionization state of a gas at a given temperature?

Consider the Hydrogen example that will interest us the most for our study of the CMB (cosmological microwave background):

$$e+p \rightleftharpoons \mathrm{H}+\gamma \tag{9.7.901}$$

Let us define the total number of baryons:

$$N_{\mathrm{b}}=N_p+N_{\mathrm{H}} \tag{9.7.902}$$

and an ionization fraction (assuming charge neutrality $N_e=N_p$):

$$x_e:=\frac{N_p}{N_b}=\frac{N_e}{n_b}=\frac{N_p}{N_p+N_{\mathrm{H}}}=\frac{N_e}{N_e+N_{\mathrm{H}}} \tag{9.7.903}$$

We can also write:

$$1-x_e=1-\frac{N_e}{(N_p+N_{\mathrm{H}})}=\frac{N_p+N_{\mathrm{H}}-N_e}{(N_p+n_{\mathrm{H}})}=\frac{N_{\mathrm{H}}}{(N_p+N_{\mathrm{H}})} \tag{9.7.904}$$

Dividing (if we divide the numerator and denominator by the volume V^2 we get densities obviously):

$$x_e^2=\frac{N_e^2}{(N_p+N_{\mathrm{H}})^2}=\frac{n_e^2}{(n_p+n_{\mathrm{H}})^2} \tag{9.7.905}$$

by the above relation, we get:

$$\frac{x_e^2}{1-x_e}=\frac{n_e^2}{(n_p+n_{\mathrm{H}})^2}\cdot\frac{(n_p+n_{\mathrm{H}})}{n_{\mathrm{H}}}=\frac{n_e^2}{(n_p+n_{\mathrm{H}})}\cdot\frac{1}{n_{\mathrm{H}}} \tag{9.7.906}$$

That latter result can also be often in the literature written as (still assuming charge neutrality!):

$$\frac{n_p n_e}{n_{\mathrm{H}} n_b}=\frac{x_e^2}{1-x_e} \tag{9.7.907}$$

We will now consider the number densities defined by a distribution function in thermal equilibrium. e and p are non-relativistic at the energy scales of recombination.

As we have proved it in the section of Electrokinetics that Maxwell-Boltzmann density states given for electrons by (see page 4294):

$$\rho_C(E)\cong 2\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2}\exp\left(\frac{\mu-E_C}{kT}\right) \tag{9.7.908}$$

So adapting that result to our case (also the notation!), and degeneracy level, it becomes:

$$n\cong g\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2}\exp\left(\frac{\mu-mc^2}{kT}\right)=g\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2}e^{-\left(mc^2-\mu\right)/kT} \tag{9.7.909}$$

Therefore, for particles and atoms involved in Hydrogen binding energy:

$$\begin{aligned}n_p&\cong g_p e^{-\left(m_p c^2-\mu_p\right)/kT}\left(m_p kT/2\pi\hbar^2\right)^{3/2}\\ n_e&\cong g_e e^{-\left(m_e c^2-\mu_e\right)/kT}\left(m_e kT/2\pi\hbar^2\right)^{3/2}\\ n_{\mathrm{H}}&\cong g_{\mathrm{H}} e^{-\left(m_{\mathrm{H}} c^2-\mu_{\mathrm{H}}\right)/kT}\left(m_{\mathrm{H}} kT/2\pi\hbar^2\right)^{3/2}\end{aligned} \tag{9.7.910}$$

We know (and we have calculated) the Hydrogen first level binding energy. We will denote it here by $B=13.605[\mathrm{eV}]$ (doing the strong assumption that ionization energy that we know today had the same value a short time after the Big Bang...). Therefore we have:

$$m_{\mathrm{H}}=m_p+m_e-B/c^2 \tag{9.7.911}$$

hence the "Saha ionization equation for Hydrogen plasma":

$$\boxed{\frac{n_p n_e}{n_{\mathrm{H}} n_b}=\frac{x_e^2}{1-x_e}\cong\frac{g_p g_e}{g_{\mathrm{H}} n_b}e^{-B/kT}e^{\left(\mu_p+\mu_e-\mu_{\mathrm{H}}\right)/kT}\left(\frac{m_e m_p}{m_{\mathrm{H}}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2}} \tag{9.7.912}$$

Remark

Some textbooks do the following complementary approximation:

$$\frac{n_p n_e}{n_{\mathrm{H}} n_b}=\frac{x_e^2}{1-x_e}\cong\frac{g_p g_e}{g_{\mathrm{H}} n_b}e^{-B/kT}e^{\left(\mu_p+\mu_e-\mu_{\mathrm{H}}\right)/kT}\left(\frac{m_e kT}{2\pi\hbar^2}\right)^{3/2} \tag{9.7.913}$$

Putting in spin degeneracy of the different components $g_p=2$, $g_e=2$, $g_{\mathrm{H}}=4$ and assuming equilibrium $\mu_p+\mu_e=\mu_{\mathrm{H}}$, we get[47]:

$$\frac{x_e^2}{1-x_e}\cong\frac{1}{n_b}e^{-B/kT}\left(\frac{m_e m_p}{m_{\mathrm{H}}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2} \tag{9.7.914}$$

---

[47] The reader must remember that $\mu_\gamma=0$ because photons are freely generated and destroyed in recombination reactions

So it's a quadratic equation involving T and the total density and without any of the μ_i. We have an exponential dominant factor: ionization drops quickly as kT drops below B - exactly where the sharp transition occurs depends on the density n_b.

After simplification and assuming $n_e=n_p$ we may also get:

$$\frac{n_e^2}{n_{\text{H}}}\cong e^{-B/kT}\left(\frac{m_e m_p}{m_{\text{H}}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2} \tag{9.7.915}$$

But another common shape is using the baryon to photon ratio $\eta=n_\gamma/n_b$ (see page 5972) to trade the rightover n_b. Then we get:

$$\frac{x_e^2}{1-x_e}\cong\frac{\eta}{n_\gamma}e^{-B/kT}\left(\frac{m_e m_p}{m_{\text{H}}}\right)^{3/2}\left(\frac{kT}{2\pi\hbar^2}\right)^{3/2} \tag{9.7.916}$$

We will use that relation in the section of Cosmology for our study of the Cosmological Microwave Background matter/photon decoupling (see page 5973).

9.7.4.4 Ionospheric propagation

The text and proofs that follow are almost a copy/paste of the course notes *Ionospheric Propagation* by Prof. Sean Victor Hum. He kindly authorized us to reproduce it here with slight modifications!

The ionosphere exists between about 90 and 1000 [km] above the earth's surface. Radiation from the Sun (actually a G2V-type star, aka yellow dwarf) ionizes atoms and molecules here, liberating electrons from molecules and creating a space of free electron and ions. Subjected to an external electric field from a radio signal, these free and ions will experience a force and be pushed into motion. However, since the mass of the ions is much larger than the mass of the electrons, ionic motions are relatively small and will be ignored here.

Free electron densities on the order of 10^{10} to 10^{12} electrons per cubic metre are produced by ionization from the sun's rays. Layers of high densities of electrons are given special names called the D, E, and F layers (during the day the F layer splits into two layers called the F_1 and F_2 layers, while the D layer vanishes completely at night). These regions do not have sharp boundaries, and the altitudes at which they occur vary during the course of a day and from season to season. The D region is the lowest, starting about 60 or 70 [km] above the ground and extending upward to about 90 [km]. Next higher is the E region, starting at about 90 or 100 [km] up and extending to 120 or 150 [km]. The uppermost part of the ionosphere, the F region, starts about 150 [km] and extends far upward, sometimes as high as 500 [km] above the surface of our home planet.

The regions of the ionosphere are not considered separate layers, such as the more familiar troposphere and stratosphere. Instead, they are ionized regions embedded within the standard atmospheric layers. The D region usually forms in the upper part of the mesosphere, while the E region typically appears in the lower thermosphere and the F region is found in the upper reaches of the thermosphere.

Before communication via satellites became common, the operators of radio communication systems often used the ionosphere to extend the range of their transmissions. Radio waves generally travel in straight lines, so unless a tall transmission tower can "see" the top of a receiver tower, the curvature of the Earth limits the range of radio transmissions to stations that are not over the horizon. However, some frequencies of radio waves bounce or reflect off of the electrically charged particles in certain ionosphere layers. Pre-satellite radio communications often took advantage of this phenomenon, bouncing radio waves off of the "sky" to extend the range of the signals. Radio operators had to account for the constant changes in the ionosphere, particularly the shifts or disappearance of the layers between day and night, to effectively take advantage of these mirror-like reflections of radio waves.

The ionosphere regions can absorb or dampen radio signals, or they can bend radio waves, as well as reflecting the signals as described above. The specific behavior depends on both the frequency of the radio signal as well as the characteristics of the ionosphere region involved. Since Global Positioning System (GPS) satellites use radio signals to determine locations, the accuracy of GPS can be severely reduced when those signals bend as they pass through ionosphere regions. Similarly, some radio communications can be disrupted if the frequency used is one that an ionosphere layer dampens or absorbs entirely, resulting in a weakened signal or even total loss of communications. Scientists constantly measure and produce computer models of the ever-changing ionosphere so that people in charge of radio communications can anticipate disruptions.

Radio waves below 40 [MHz] are significantly affected by the ionosphere, primarily because radio waves in this frequency range are effectively reflected by the ionosphere. The E and F layers are the most important for this process. For frequencies beyond 40 [MHz], the wave tend to penetrate through the atmosphere versus being reflected.

The major usefulness of the ionosphere is that the reflections enable wave propagation over a much larger distance than would be possible with line-of-sight or even atmospheric refraction effects. This is shown graphically below:

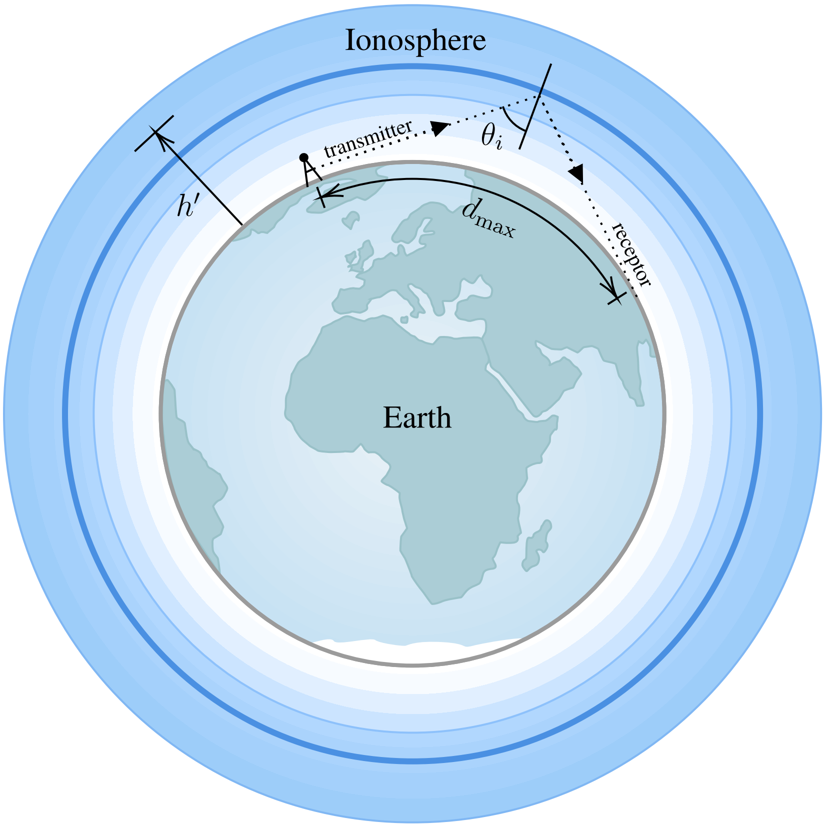

Figure 9.289: **A single skip of a radio wave using the ionosphere**

The skip distance $d_{\max}$ can be very large, allowing very large communication distances. This is further enhanced by multiple reflections between the ionosphere and the ground, leading to multiple skips. This form of propagation allows shortwave and amateur radio signals to propagate worldwide. Since the D layer disappears at night, the best time for long-range communications is at night, since the skip distance is larger as the E, and F regions are at higher altitudes.

Where does the reflection come from? The reflections from the ionosphere are actually produced by refraction as the wave propagates through the ionosphere. The ionosphere is a concentrated region highly charged ions and electrons that collective form an ionized gas or plasma. This gas has a dielectric constant that is a function of various parameters, including the electron concentration and the frequency of operation. We now derive the dielectric constant of a plasma.

The electric field will produce a force on a given electron and displace it along a vector $\vec{r}$, as shown on the left side of the figure below:

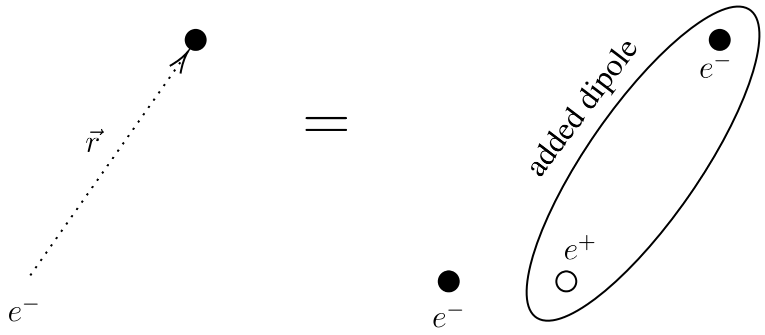

Figure 9.290: **Representation of a moving electron as a dipole moment**

The displacement of an electron along this path can be modelled in an equivalent situation where the original electron remained stationary and an equivalent electric dipole is added, as shown in the right half of the figure. The dipole moment of this dipole is then equal to $-e\vec{r}$ (see section Electrostatics page 3986). If there are N electrons per unit volume, each displaced by $\vec{r}$ on average, then the volume polarization is:

$$\vec{P}=-Ne\vec{r} \tag{9.7.917}$$

The equation of motion for a single electron of mass $m_e=9.109\cdot 10^{-31}$ [kg], charge $e=1.6021\cdot 10^{-19}$ [C], with velocity $\vec{v}=\mathrm{d}\vec{r}/\mathrm{d}t$, and acted upon by an electric field $\vec{E}$, is:

$$m_e\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=-e\vec{E} \tag{9.7.918}$$

The electron also experiences a frictional force resulting from collisions with neutral molecules. This force is added to the electric field force above, yielding:

$$m_e\frac{\mathrm{d}\vec{v}}{\mathrm{d}t}=-e\vec{E}-\nu m_e\vec{v} \tag{9.7.919}$$

where ν is the electron collision frequency. Re-writing the equation in terms of $\vec{r}$:

$$m_e\frac{\mathrm{d}^2\vec{r}}{\mathrm{d}t^2}=-e\vec{E}-\nu m_e\frac{\mathrm{d}\vec{r}}{\mathrm{d}t} \tag{9.7.920}$$

We know that for sinusoidal fields, we can write equations in terms of phasors (see section Wave Mechanics page 3510) and replace $\mathrm{d}/\mathrm{d}t$ with $\mathrm{i}\omega$. Hence we can write the equation of motion on the electron in terms of phasors as:

$$-\omega^2 m_e\vec{r}=-e\vec{E}-\mathrm{i}\omega\nu m_e\vec{r} \tag{9.7.921}$$

Or:

$$\vec{r}=\frac{e\vec{E}}{\omega^2 m_e-\mathrm{i}\omega\nu m_e}=\frac{e\vec{E}}{m_e\omega^2\left(1-\mathrm{i}\frac{\nu}{\omega}\right)} \tag{9.7.922}$$

Substituting this into $\vec{P}=-Ne\vec{r}$, we get:

$$\vec{P}=-\frac{Ne^2\vec{E}}{m_e\omega^2\left(1-\mathrm{i}\frac{\nu}{\omega}\right)} \tag{9.7.923}$$

The electric flux density can then be found as (see section Electromagnetism page 4108):

$$\vec{D}=\varepsilon_0\vec{E}+\vec{P}=\varepsilon_0\vec{E}-\frac{Ne^2\vec{E}}{m_e\omega^2\left(1-\mathrm{i}\frac{\nu}{\omega}\right)}\equiv\varepsilon_r\varepsilon_0\vec{E} \tag{9.7.924}$$

The "effective relative dielectric constant" of the plasma is then defined by:

$$\varepsilon_r=1-\frac{Ne^2}{m_e\omega^2\varepsilon_0\left(1-\mathrm{i}\frac{\nu}{\omega}\right)} \tag{9.7.925}$$

An "angular plasma frequency" can be defined such that:

$$\omega_p^2=\frac{Ne^2}{m_e\varepsilon_0}\cong 3,183N \tag{9.7.926}$$

We see that in the presence of electron collisions, the dielectric constant can in general be complex. If we ignore collisions for the moment (i.e. $\nu=0$), then:

$$\varepsilon_r=1-\frac{\omega_p^2}{\omega^2}\approx 1-\frac{81N}{f^2} \tag{9.7.927}$$

This relation is knows as the "Eccles relation".

Let us now consider an infinite plane-wave, of frequency, ω so that the wave electric field takes the form:

$$\vec{E}=E_0e^{\mathrm{i}(kx-\omega t)}\hat{\vec{z}} \tag{9.7.928}$$

where it is understood that the physical electric field is the real part of the above expression. A peak or trough of the above wave travels at the so-named "phase velocity", which is for recall given by (see section Mechanics page 3480):

$$v_p=\frac{\omega}{k} \tag{9.7.929}$$

Now, we have also seen that the phase velocity of electromagnetic waves in a dielectric medium is $v_p=c/n=c/\sqrt{\varepsilon}$ (see section Electromagnetism page 4243), so:

$$\omega^2=\frac{k^2c^2}{\varepsilon} \tag{9.7.930}$$

It follows from :

$$\varepsilon_r=1-\frac{\omega_p^2}{\omega^2} \tag{9.7.931}$$

that:

$$\omega^2=k^2c^2+\omega_p^2 \tag{9.7.932}$$

in a plasma. Hence:

$$k=\sqrt{\frac{\omega^2-\omega_p^2}{c^2}}=\frac{\mathrm{i}\sqrt{\omega_p^2-\omega^2}}{c}:=\mathrm{i}|k| \tag{9.7.933}$$

Therefore, the wave electric field takes the form:

$$E_z=E_0e^{\mathrm{i}(\mathrm{i}|k|x-\omega t)}=E_0e^{-|k|x}e^{-\mathrm{i}\omega t} \tag{9.7.934}$$

Indeed, it can be seen that for $\omega<\omega_p$ electromagnetic waves in a plasma take the form of decaying standing waves, rather than travelling waves. We conclude that an electromagnetic wave, of frequency less than the plasma frequency, which is incident on a plasma will not propagate through the plasma. Instead, it will be totally reflected.

We can be sure that the incident wave is reflected by the plasma, rather than absorbed, by considering the energy flux of the wave in the plasma. We have demonstrated that the Poynting vector can be written (see section Electromagnetism page 4156):

$$\vec{S}=\frac{E^2}{\mu_0\omega}\vec{k} \tag{9.7.935}$$

For a wave with a real frequency and a complex $\vec{k}$-vector, the above relation reduces to:

$$\vec{S}=\frac{E^2}{\mu_0\omega}\Re(\vec{k}) \tag{9.7.936}$$

However, according to:

$$k=\sqrt{\frac{\omega^2-\omega_p^2}{c^2}}=\frac{\mathrm{i}\sqrt{\omega_p^2-\omega^2}}{c}:=\mathrm{i}|k| \tag{9.7.937}$$

the $\vec{k}$-vector for a low frequency electromagnetic wave in a plasma is purely imaginary. It follows that the associated energy flux is zero. Hence, any low frequency wave which is incident on the plasma must be totally reflected, since if there were any absorption of the wave energy then there would be a net energy flux into the plasma.

From these observations we can observe two propagation mechanisms for a wave entering the ionosphere. If it is below the plasma frequency, it is simply reflected off the ionosphere. When it is above the plasma frequency, then refraction analogous to that which occurs with atmospheric refraction occurs, though it is much more pronounced because of the large changes in refractive index. In fact, provided the angle at which the wave enters the atmosphere is not too steep, the wave will be bent quite strongly as it enters ionosphere. If the angle of incidence reaches the critical angle (see section Optics page 4369) for total internal reflection, the wave is reflected off the ionosphere and starts to return to Earth, going through the reverse process of refraction as it does so.

The world ground-to-ground radio transmission worldwide record using ionospheric propagation at the day we write these lines was done the 1st January 12020 (holocene calendar), by the amateur radio Nick G4KUX (radio nickname) in the county of Durham in the north of England who managed to work D41CV also on FT8 on 432 [MHz] to $4,644$ kilometres. Nick, G4KUX lives in an elevated location to the west of Bishop Auckland in County Durham in the north of England. His location is about 360 metres above sea level and he has a good take off for radio in all directions. For the record breaking contact with D41CV on Cape Verde Island, Nick was using 400 Watts into a UHF Log-Periodic antenna.

For more detailed and modern approaches than the above one see *The propagation of radio waves over the surface of the earth and in the upper atmosphere* ([419]) and *The ancient and modern history of EM ground-wave propagation* ([565]).

10.1. Electrostatics

So far we have focus only on the gravitational interaction and the characteristic quantity of matter, named "mass" associated with it. We discussed the electromagnetic interaction, analysing macroscopic phenomena such as friction, cohesion, elasticity, the forces of contact, etc. Now we look at electronic forces and the characteristic of matter named "electric charge" associated with them. The electromagnetic interaction binds matter in all its observable forms. It is this that holds the electrons to the nucleus in the atom, which holds together the atoms in molecules, molecules into objects and even your nose to your face...

The "electric charge" generates the "electric force" or "Coulomb force" and we are only beginning to understand this force thanks to Quantum Field Theory (see further below in this textbook). The electric charge is a fundamental concept, which can not be described in terms of more simple and fundamentals concepts. We know it by its effects and unfortunately not by what it is (this was also the case for the mass before the discovery of the Higgs Boson).

Experience has also shown that even if the electric charge is an additive quantity such as the mass, however, it also has negative value (and not exclusively positive as known nowadays for the mass). Thus, in the current language, and as confirmed by experience, two identical sign electric charges repel and two opposite sign electric charges attract (we will see a schematic figure of this further below).

Figure 10.1: **Electric charges exist all around us. They can cause objects to be repelled from each other or to be attracted to each other (credit: modification of work by Sean McGrath)**

People should be wary of charlatans - especially self-proclaimed telekinetics - who exploit simple electrostatic tricks to create the illusion of mystical powers. By subtly charging objects or manipulating lightweight materials, these performers can make items move or react in ways that seem supernatural to the untrained eye. Their goal is not to reveal hidden truths about the universe but to deceive, impress, and ultimately extract money from individuals who may not be familiar with the underlying physics (that's why the will reject to accept to be tested with an electrostatic fieldmeter). Understanding that these effects rely on basic electrostatics, not paranormal abilities, is essential to avoiding manipulation and protecting oneself from financial exploitation.

Let us now see the classic force that is associated with the electric charge:

10.1.1 Electric Force

It has experimentally been established by Coulomb that a reference point particle undergoes a force $\vec{F}$ of an intensity proportional to its charge q, when placed in the neighbourhood of one or more electrical charges Q_i in a medium of absolute electrical permittivity ε (permittivity to the electric field of course...!) given in vector notation and in non-relativistic case by:

$$\vec{F}=q\left(\frac{1}{4\pi\varepsilon}\sum_i\frac{Q_i}{||\vec{r}-\vec{r}_i||^3}(\vec{r}-\vec{r}_i)\right)=q\left(\frac{1}{4\pi\varepsilon}\sum_i\frac{Q_i}{||\vec{r}-\vec{r}_i||^2}\vec{u}_i\right) \tag{10.1.1}$$

where $\vec{r}_i$ is the vector position of the sample charge Q_i and $\vec{r}$ of the reference point charge particle relatively to a same orthonormal vector basis.

In other words, two point electric charged particles attract or repel each other in a force directly proportional to their electric charge and inversely proportional to the square of the distance that separates them.

In the case of a system with two particles separated by a distance r, we have the same simplified relation and we fall back on the most common form of the electric force or "Coulomb force" as given in most textbooks (as scalar and non-relativistic):

$$\boxed{F=\frac{1}{4\pi\varepsilon}\frac{Qq}{r^2}=\frac{1}{4\pi\varepsilon}\frac{q_1q_2}{r^2}} \tag{10.1.2}$$

Hence recalling Newton's second law:

$$F=ma=\frac{1}{4\pi\varepsilon}\frac{Qq}{r^2}=\frac{1}{4\pi\varepsilon}\frac{q_1q_2}{r^2} \tag{10.1.3}$$

Frequently, these relation is defined as the "Coulomb's law" in most schools and admitted as unprovable. In fact, it is not! This relation can be proved as we will see in the study of quantum fields physics (see section Quantum Field Theory page 5164) using the Klein-Gordon equation in the context of a potential field with spherical symmetry (proof performed by Hideki Yukawa).

The law was discovered in 11785 (holocene calendar) by the French physicist Charles-Augustin de Coulomb through a series of memoirs on electricity and magnetism (see [115]). Especially he used a torsion balance (based on torsion pendulum) that is today named the "Coulomb balance" that plenty of high-school around the World have in their physics lab:

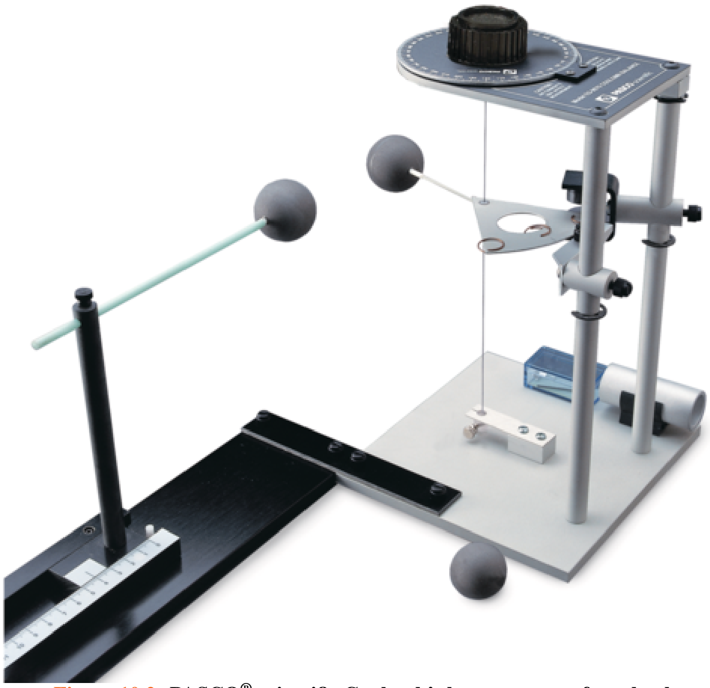

Figure 10.2: **PASCO® scientific Coulomb's law apparatus for schools**

Remark

Don't forget that as 2π appears frequently in many theorems of physics and mathematics (more than π alone), the value 4π is frequently denoted by 2τ as by definition $\tau = 2\pi$.

In either formulation, Coulomb's law is fully accurate only when the objects are stationary, and remains approximately correct only for slow movement. These conditions are collectively known as the electrostatic approximation. When movement takes place, magnetic fields that alter the force on the two objects are produced. The magnetic interaction between moving charges may be thought of as a manifestation of the force from the electrostatic field but with Einstein's theory of relativity taken into consideration.

Remark

For the relativistic form of Coulomb's law, the reader is referred to the section Special Relativity (see 5699) where it is proved that (vector form):

$$\vec{F} = \frac{q(1-v^2/c^2)}{\left[1-(v^2/c^2)\sin^2(\theta)\right]^{2/3}} \frac{Q\vec{r}}{4\pi\varepsilon r^3} \qquad (10.1.4)$$

The value of electric permittivity in vacuum (as we will see during our study of Quantum Field Theory, vacuum isn't really empty) is in turn given experimentally by the "dielectric constant" or simple "electric constant":

$$\varepsilon_0 \cong 8.8541878176\ldots \cdot 10^{-12} \;\left[\mathrm{C}^2 \cdot \mathrm{N}^{-1} \cdot \mathrm{m}^{-2}\right] \qquad (10.1.5)$$

and relatively to medium considered, we define a "relative dielectric permittivity" ε that makes it easier to determine the properties of a material with respect to the electric field so that we have the "absolute electrical permittivity":

$$\varepsilon = \varepsilon_0 \varepsilon_r \tag{10.1.6}$$

It should be mentioned that some authors define the permittivity of vacuum from the speed of light and the magnetic permeability of vacuum (see section Magnetostatics page 4011). Therefore, the value of the electrical permittivity of vacuum is obviously correct by definition. But this only makes sense once known the Maxwell's theory and this will be presented and proved later in the section Electrodynamics (we follow the steps in the historical scientific discoveries).

The SI unit of permittivity is (sadly) the "farad" per meter, such that:

$$\frac{\mathrm{F}}{\mathrm{m}} = \frac{\mathrm{C}}{\mathrm{V}\cdot\mathrm{m}} = \frac{\mathrm{C}^2}{\mathrm{N}\cdot\mathrm{m}^2} = \frac{\mathrm{C}^2\cdot\mathrm{s}^2}{\mathrm{kg}\cdot\mathrm{m}^3} = \frac{\mathrm{A}^2\cdot\mathrm{s}^4}{\mathrm{kg}\cdot\mathrm{m}^3}$$

It also appears in the Coulomb force constant, as the "Coulomb constant":

$$K_e = \frac{1}{4\pi\varepsilon_0} \tag{10.1.7}$$

The factor into parentheses in:

$$\vec{F} = q\left(\frac{1}{4\pi\varepsilon}\sum_i \frac{Q_i}{\|\vec{r}-\vec{r}_i\|^3}(\vec{r}-\vec{r}_i)\right) \tag{10.1.8}$$

depends only on the distribution of charges Q_i in the volume and the absolute electrical permittivity of the medium ε. Since its value varies from one place to another and depends on the position vector $\vec{r}$ of the reference electric charge, it forms a set of vectors, which property is this of a multitude of electrical field lines hence the use of the term "electric field".

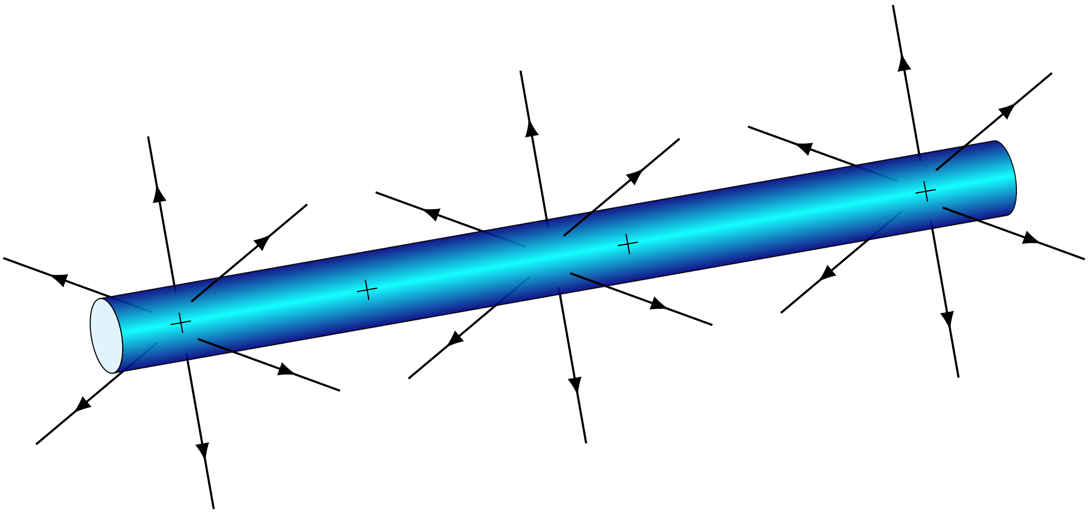

Figure 10.3: **Electric field of an infinite line charge**

The set of these vectors $\vec{E}$ carries therefore the name "electric field", at the point $\vec{r}$,developed in the electric charge distribution Q_i:

$$\vec{E}=\frac{1}{4\pi\varepsilon}\sum_i \frac{Q_i}{\|\vec{r}-\vec{r}_i\|^3}(\vec{r}-\vec{r}_i) \qquad (10.1.9)$$

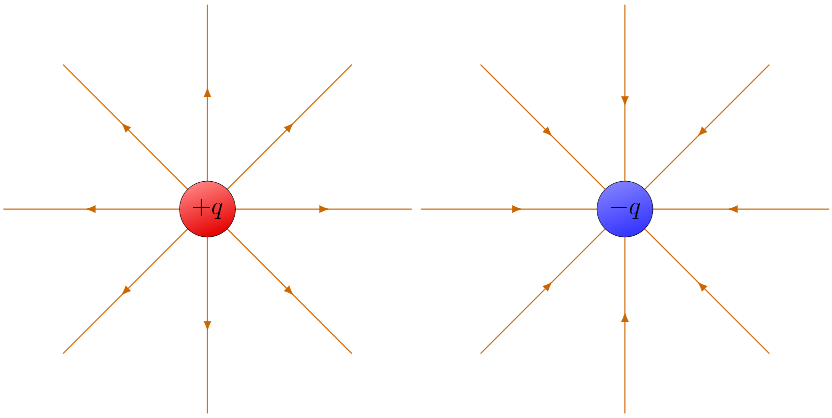
Engineers often use another notation that allows to characterize only the geometry of the field regardless the environment (medium) and for this purpose they introduce the concept of "displacement field":

$$\boxed{\vec{D}=\varepsilon\vec{E}=\varepsilon_0(1+\chi)\vec{E}} \qquad (10.1.10)$$

where χ is the "electric susceptibility". We will meet this vector again in the section Electrodynamics during our synthesis of Maxwell's equations.

Coulomb force acting on the sample charge q, is then written in a conventional way (hence the electric field can simple be interpreted as the force per unit charge!):

$$\boxed{\vec{F}=q\vec{E}(\vec{r})} \qquad (10.1.11)$$



One configuration is of particular interest: two separated point charges of opposite charge. In the limit of vanishing separation, it is named "dipole". Its field fundamentally differs from that of just a single charge even though it is just the sum of the charge. The dipole as a concept is extremely important throughout electrodynamics. It is applied for example to explain the emission of electromagnetic radiation or as a model for molecules.

Let us first consider the case of opposite electric charges. For the given problem we have $\vec{r}_1=-d/2\vec{e}_x$ and $\vec{r}_2=d/2\vec{e}_x$. So the charges lie on the x-axis with a separation d. Remember that $\vec{e}_x$ is the unit vector in x direction (see section Vector Calculus page 1794). The electric field is then given by:

$$\begin{aligned}\vec{E}(\vec{r})=\vec{E}(x,y,z)&=\frac{1}{4\pi\varepsilon}\left(Q\frac{\vec{r}-\vec{r}_1}{\|\vec{r}-\vec{r}_1\|^3}+(-Q)\frac{\vec{r}-\vec{r}_2}{\|\vec{r}-\vec{r}_2\|^3}\right)\\&=\frac{Q}{4\pi\varepsilon}\left(\frac{(x-d/2)\vec{e}_x+y\vec{e}_y+z\vec{e}_z}{[(x-d/2)^2+y^2+z^2]^{3/2}}-\frac{(x+d/2)\vec{e}_x+y\vec{e}_y+z\vec{e}_z}{[(x+d/2)^2+y^2+z^2]^{3/2}}\right)\end{aligned} \qquad (10.1.12)$$

Imagine we are interested in the magnitude and the direction of the field only about the line of the y-axis. To figure it out both, we simply calculate:

$$\begin{aligned}\vec{E}(x=0,y,z=0)&=\frac{Q}{4\pi\varepsilon}\left(\frac{-d/2\vec{e}_x+y\vec{e}_y}{[(-d/2)^2+y^2]^{3/2}}-\frac{(+d/2)\vec{e}_x+y\vec{e}_y}{[(+d/2)^2+y^2]^{3/2}}\right)\\&=\frac{Q}{4\pi\varepsilon}\frac{d\vec{e}_x}{[(-d/2)^2+y^2]^{3/2}}\end{aligned}\tag{10.1.13}$$

We see that the electric field has only a component in x-direction. Because of the symmetric choice of the coordinate system we could have guessed this in the first place.

The magnitude is therefore given by the norm of the electric field:

$$\|\vec{E}(x=0,y,z=0)\|=\frac{Q}{4\pi\varepsilon}\frac{d}{[(d/2)^2+y^2]^{3/2}}=\frac{Q}{4\pi\varepsilon}\frac{1}{d^2}\frac{1}{[(1/2)^2+(y/d)^2]^{3/2}}\tag{10.1.14}$$

Let us now consider the case of equal charges (positive for example):

$$\begin{aligned}\vec{E}(x=0,y,z=0)&=\frac{Q}{4\pi\varepsilon}\left(\frac{-d/2\vec{e}_x+y\vec{e}_y}{[(-d/2)^2+y^2]^{3/2}}+\frac{(+d/2)\vec{e}_x+y\vec{e}_y}{[(+d/2)^2+y^2]^{3/2}}\right)\\&=\frac{2Q}{4\pi\varepsilon}\frac{y\vec{e}_y}{[(d/2)^2+y^2]^{3/2}}\end{aligned}\tag{10.1.15}$$

The direction of the field is in this case always parallel to the y-axis but changing sign at $y=0$. Its magnitude is given by:

$$\|\vec{E}(x=0,y,z=0)\|=\frac{2Q}{4\pi\varepsilon}\frac{|y|}{[(d/2)^2+y^2]^{3/2}}=\frac{2Q}{4\pi\varepsilon}\frac{1}{y^2}\frac{1}{[(d/2y)^2+1]^{3/2}}\tag{10.1.16}$$

We find that for equal charges the magnitude of the electric field decreases for large y.

With Maple™ 4.00b we can easily plot these two magnitudes:

```
>plot(1/(0.5^2+y^2)^(3/2),1/(y^2)*1/((1/(2*y))^2+1)^(3/2),y=-5..5);
```

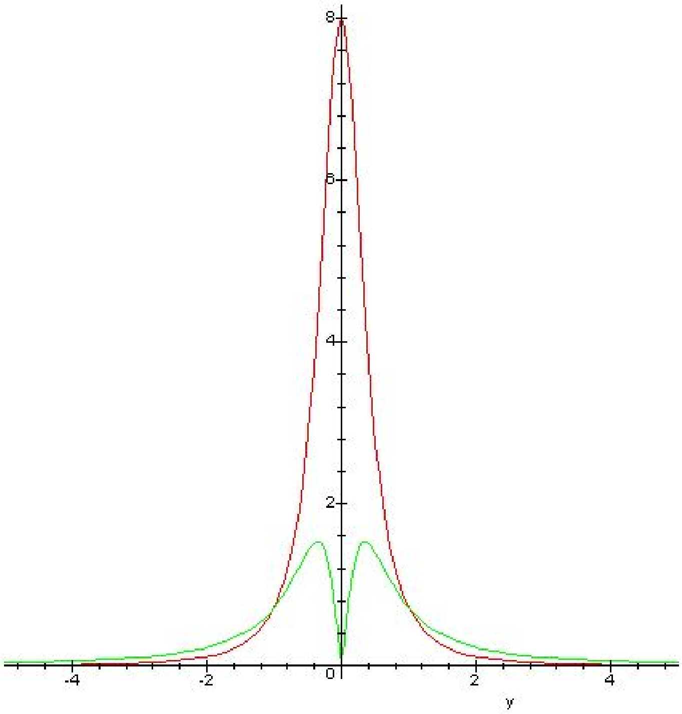


Figure 10.4: **Dipole profile for $q_1 = -q_2$ and $q_1 = q_2$ along y-axis**

This is how looks like some lines of electric field of two identical charges particles ($q_1 = q_2$) with a nice perspective effect:

Figure 10.6: **Various typical electric fields configurations (author: Izaak Neutelings)**

10.1.2 Electric Potential

Given two points A and B in a region of space where there is an electric field $\vec{E}(x,y,z)$ and given Γ a path connecting these two points. So, in the particular case where the source of a field $\vec{E}$ is a sphere or a punctual body and we put a charge as its neighbourhood, we have for the work done by the force to move the charge from point A to point B:

$$\begin{aligned}\mathrm{d}W_{A,B}=\vec{F}\circ\mathrm{d}\vec{r}\Rightarrow\int\limits_A^B\vec{F}\circ\mathrm{d}\vec{r}=q\int\limits_A^B\vec{E}\circ\mathrm{d}\vec{r}=q\int\limits_A^B E\cos(\alpha)\mathrm{d}r=q\int\limits_A^B E\mathrm{d}r=q\frac{Q}{4\pi\varepsilon}\int\limits_A^B\frac{1}{r^2}\mathrm{d}r\\=q\frac{Q}{4\pi\varepsilon}\left(-\frac{1}{r_B}+\frac{1}{r_A}\right)=q\frac{Q}{4\pi\varepsilon}\left(\frac{1}{r_A}-\frac{1}{r_B}\right)\end{aligned}\tag{10.1.17}$$

Moreover, this work is as we shall see, equivalent to the potential energy. We thus define the "potential difference" or simply the "potential" by the relation:

$$-\Delta U=\frac{Q}{4\pi\varepsilon}\left(\frac{1}{r_B}-\frac{1}{r_A}\right)=U_B-U_A\tag{10.1.18}$$

and therefore:

$$\boxed{\Delta U=-\int\vec{E}\circ\mathrm{d}\vec{r}=-\int E\mathrm{d}r}\tag{10.1.19}$$

measured in Volts [V], or equivalently in $\left[\mathrm{J}\cdot\mathrm{C}^{-1}\right]$.

In other words, the "difference in electric potential" between two points (i.e., voltage) in a static electric field is defined as the work needed per unit of charge to move a test charge between the two points.

The work can then be written:

$$\Delta W_{A,B}=q\Delta U\tag{10.1.20}$$

Remarks

R1. The potential is often named "voltage" by electricians, electrical engineers and other engineers and the unit of measurement of the potential that is the "Volt" denoted by [V].

R2. The potential difference can either exists between two terminals of opposite charge $(+,-)$, or between two terminals of the type $(+,\text{neutral})$ or also $(-,\text{neutral})$. The latter two cases represents typically the configuration used by trains, trams, storms and almost all electromechanical appliances.

Theorem 10.1. We will now show in the more general framework that exists that the stationary vector field $\vec{E}$ derivates from a potential field:

Proof 10.1.1. Given a charge Q located relative to a reference frame by the vector $\vec{r}_Q$. Then in each point of space there exists a field $\vec{E}$ such as:

$$\vec{E}(\vec{r})=\underbrace{\frac{1}{4\pi\varepsilon}}_{=k_e}\frac{Q}{\|\vec{r}-\vec{r}_Q\|^3}(\vec{r}-\vec{r}_Q)\tag{10.1.21}$$

let us develop this expression:

$$\vec{E}(x,y,z)=\frac{k_eQ}{[(x-r_{Q_x})^2+(y-r_{Q_y})^2+(z-r_{Q_z})^2]^{3/2}}\begin{pmatrix}x-r_{Q_x}\\y-r_{Q_y}\\z-r_{Q_z}\end{pmatrix}\tag{10.1.22}$$

If $\vec{E}$ is a stationary potential field then, there must be a potential $\Phi(x,y,z)$ of this field which satisfies:

$$\frac{\partial\Phi}{\partial x}(x,y,z)=E_x(x,y,z).\ \frac{\partial\Phi}{\partial y}(x,y,z)=E_y(x,y,z),\ \frac{\partial\Phi}{\partial z}(x,y,z)=E_z(x,y,z)\tag{10.1.23}$$

Let us look to the potential Φ exists for a Coulomb field. Then we must have for the field in x:

$$\frac{\partial\Phi}{\partial x}=E_x=\frac{KQ}{[(x-r_{Q_x})^2+(y-r_{Q_y})^2+(z-r_{Q_z})^2]^{3/2}}(x-r_{Q_x})\tag{10.1.24}$$

therefore:

$$\Phi(x,y,z)=-k_eQ[(x-r_{Q_x})^2+(y-r_{Q_y})^2+(z-r_{Q_z})^2]^{-1/2}+c^{te}\tag{10.1.25}$$

and if we do the same development for each component, we also get the same result. Thus the electric potential is a scalar field and not a vector field (the electric field is it obviously a vector field)!

■ Q.E.D.

The potential $\Phi(x,y,z)$ is named in the case of a Coulomb field of "Coulomb potential" and is conventionally chosen such that:

$$\Phi(x,y,z)=-U\tag{10.1.26}$$

As we can see it by the prior-previous expression of $\Phi(x,y,z)$, c^{te} is an arbitrary constant, which imposes in the case of absence of charges that:

$$U=0\tag{10.1.27}$$

Which finally gives us:

$$E_x=-\frac{\partial U}{\partial x},\ E_y=-\frac{\partial U}{\partial y},\ E_z=-\frac{\partial U}{\partial z}\tag{10.1.28}$$

Giving for all components:

$$\vec{E}=-\begin{pmatrix}\dfrac{\partial}{\partial x}\\\dfrac{\partial}{\partial y}\\\dfrac{\partial}{\partial z}\end{pmatrix}\cdot U\tag{10.1.29}$$

that we write in a more condensed way:

$$\boxed{\vec{E}=-\vec{\nabla}\cdot U=-\overrightarrow{\text{grad}}(U)}\tag{10.1.30}$$

A common concept that you can find in many electromagnetic compatibility standards for humans (especially) but also for machines is the "step voltage" that is just the difference in potential measured between two point distant of 1 meter. In other words it's just the electric field value. Near some high-voltage installations, the step voltage can kill humans or other animals.

The resistance of the human body is roughly between $1,000$ and $1,000$ ohms. Then we have the following typical table:

Current	**Required Voltage**		**Comments**	
	$1,000$ $[\Omega]$	$100,000$ $[\Omega]$		
1 $[\text{mA}]$	1 $[\text{V}]$	100 $[\text{V}]$	Threshold of feeling, tingling sensation	
15 $[\text{mA}]$	5 $[\text{V}]$	500 $[\text{V}]$	Maximum current level a human can withstand before sustaining injury	
$15-20$ $[\text{mA}]$	10 $[\text{V}]$	$1,000$ $[\text{V}]$	Beginning of sustained muscular contraction ("can't let go" current)	extreme pain
$100-300$ $[\text{mA}]$	100 $[\text{V}]$	$10,000$ $[\text{V}]$	Ventricular fibrilation, fatal if continued. Respiratory function continues.	burns, permanent damage, or death
6 $[\text{A}]$	$6,000$ $[\text{V}]$	$600,000$ $[\text{V}]$	Sustained ventricular contraction followed by normal heart rhythm (defibrilation). Temporary respiratory paralysis and burns	

Figure 10.7: **Various voltage values relative to human body health**

Mobile phone 3G and 4G antenna seem to have a step voltage (depending on various countries regulations) between $11\,[\text{V}\cdot\text{m}^{-1}]$ and $58\,[\text{V}\cdot\text{m}^{-1}]$ at the day we write these lines. This is a higher value than the step voltage of a hair dryer, a toaster, a mixer, a fridge or even in comparison of Earth natural step voltage that is over land in average around[1] $120\,[\text{V}\cdot\text{m}^{-1}]$.

Definition (#10.1.477): The "electricity" is the set of physical phenomena associated with the presence and motion of matter possessing an electric charge. Electricity can be directly observed thanks to thunder for example or electric arcs.

> Remark
>
> The same developments and results (and those that follow) are applicable regarding the gravitational potential field. However, they rarely are made in the literature or schools because the human being does not control (at least until now) the gravitational field with an ease and intensity equivalent to that of the electric field...

It therefore follows that:

$$\vec{F}=q\vec{E}=-q\vec{\nabla}\cdot U \qquad (10.1.31)$$

and so for example for a spherical symmetric potential (case that we will find in many other sections of this textbook), it comes:

---

[1] According to the study Atmospheric Electricity, Grupo de Eletricidade Atmosférica (ELAT), Instituto Nacional de Pesquisas Espaciais, June 12005 (holocene calendar).

$$F=\|\vec{F}\|=\left|-q\frac{\mathrm{d}U}{\mathrm{d}R}\right| \tag{10.1.32}$$

10.1.2.1 Path Independence

Let us prove now that the potential difference between two points A and B is independent of the path Γ travelled such as we did for the gravitational potential field in the section of Classical Mechanics.

Given Γ a path between two points A and B and a field $\vec{E}$ and let us make so that we can express the field on x, y and z with respect to a single variable t (which has nothing to do with time...) that would account for its magnitude change for any movement between these two points:

$$\vec{E}\circ\mathrm{d}\vec{r}=-\left(\vec{\nabla}\cdot U(r(t))\right)\circ\mathrm{d}\vec{r} \tag{10.1.33}$$

So with A corresponding to the value t_1 of the parametrization and B to the value t_2.

But, we know that (see section Differential and Integral Calculus page 1466) that:

$$\mathrm{d}f=\frac{\partial f}{\partial x}\mathrm{d}x+\frac{\partial f}{\partial y}\mathrm{d}y+\frac{\partial f}{\partial z}\mathrm{d}z=\partial_x f\mathrm{d}x+\partial_y f\mathrm{d}y+\partial_z f\mathrm{d}z=(\vec{\nabla}\cdot f)\circ\mathrm{d}\vec{r} \tag{10.1.34}$$

Therefore it comes:

$$\vec{E}\circ\mathrm{d}\vec{r}=-\mathrm{d}U(r(t)) \tag{10.1.35}$$

Therefore:

$$\underbrace{-\int_{\Gamma}\vec{E}\circ\mathrm{d}\vec{r}}_{=\Delta U}=\int_{t_1}^{t_2}\mathrm{d}U(r(t))=U(r(t))\Big|_{t_1}^{t_2}=U(r(t_2))-U(r(t_1)) \tag{10.1.36}$$

This last expression shows that U is independent of the path Γ regardless of the way we parametrize it.

The Coulomb field is therefore a "conservative vector field" Indeed, if we consider a closed path Γ and A and B are two confused points of the part then the potential difference will be zero!

Notice that sometimes we also say that the gradient of the potential is conservative.

10.1.3 Equipotential and Field lines

Now we can from what we have built, define the "equipotentials" and "field lines".

Given a Coulomb field defined relatively to a given repository (reference frame). Then at each point (x, y, z) of space, we can associate an electric field vector $\vec{E}(x, y, z)$ and an electric potential.

Definition (#10.1.478): The "field lines" is a family of curves for which the vector $\vec{E}(x, y, z)$ is tangent and constant at each point and the "equipotentials" as the lines for which the potential $U(x, y, z)$ are also constant.

Theorem 10.2. In this case, and that is what we will show, all field lines are perpendicular to all equipotentials if the vector field derived from a potential.

Let us use the property conservation of the Coulomb field for the proof:

Proof 10.2.1.

$$\Delta U = -\oint_{\Lambda} \vec{E} \circ \mathrm{d}r = U(B) - U(A) = 0 \tag{10.1.37}$$

As we are in the presence of an electric field, this therefore derives from a potential as we know. This implies that if the field is not null the potential there is also not. So in the line integral:

$$\Delta U = -\oint_{\Lambda} \vec{E} \circ \mathrm{d}r \tag{10.1.38}$$

one of the terms is zero! This is not the electric field $\vec{E}$ as we are in presence of one, which discredits the potential U and as the charge moves, $\mathrm{d}\vec{r}$ is not null either. Then write the line integral in another way:

$$\Delta U = -\oint_{\Lambda} \vec{E} \circ \mathrm{d}r = -\oint_{\Lambda} E \circ \mathrm{d}r \cos(\alpha) = 0 \Leftrightarrow \frac{\mathrm{d}U}{\mathrm{d}r} = -E\cos(\alpha) = 0 \Leftrightarrow \frac{\left(\dfrac{\mathrm{d}U}{\mathrm{d}r}\right)}{E} = \cos(\alpha) = 0 \tag{10.1.39}$$

Therefore:

$$\alpha = \frac{\pi}{2} \tag{10.1.40}$$

We can then conclude that the equipotentials are perpendicular to the lines of the electric field and vice versa. This is what was to be proved.

■ Q.E.D.

Here are examples of level lines including field lines and equipotential lines obtained using Maple™ 4.00b (we will show in our study of differential equations how to get the mathematical functions of the field lines):

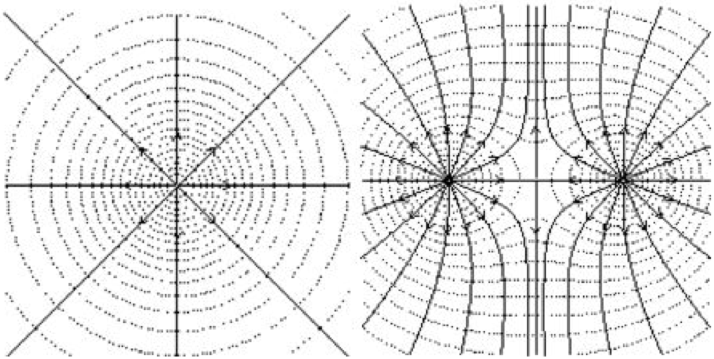

Figure 10.8: **Left: a single charge - Right: two charges of the same sign**

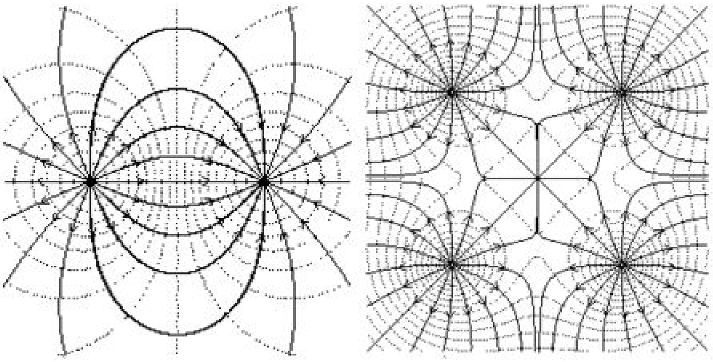

Figure 10.9: **Left: two charges of opposite signs - Right: four charges of the same sign**

> **Remark**
>
> Apart from the opposite charges, we recall that the same results are applicable to the masses with the gravitational field!

Two applications of these results are very important (for which we will limit ourselves to the study of the most important properties):

1. The determination of the field lines and equipotential lines for an infinite straight wire such as we can consider in approximation in the electric circuits or high voltage overhead lines (to determine the influence of fields from wires with their environment - this study is part of the branch of electro-engineering we name EMC for "ElectroMagnetic Compatibility"). The results can also be used to determine the "voltage step" for some rectilinear systems which determines for a given distance, the potential per meter for which a mammal may be killed by electroshock near such a wire. An extension (which I do not wish to deal even if the subject is exciting but very controversial) is also the influence of this type of potential on the functioning of the human brain in the case of the use of portable phones (antennas transmitting a potential) or about houses near high voltage power lines...

   > **Remark**
   >
   > We will determine in the section of Magnetostatics the Biot and Savart law giving the magnetic field for such a wire carrying a given current intensity.

2. The determination of the field lines and equipotential of an electric dipole has a huge importance in chemistry. We will also see what is the dynamics of it when immersed in a

uniform electric field and the energy of interaction between dipoles (as is often the case in chemistry).

10.1.3.1 Infinite straight wire

Given:

$$\vec{u}_r=\frac{\vec{r}}{\|\vec{r}\|} \tag{10.1.41}$$

We have:

$$\mathrm{d}\vec{E}=\frac{1}{4\pi\varepsilon}\frac{\mathrm{d}q}{r^2}\vec{u}_r \tag{10.1.42}$$

by making use of the concept of linear charge density as we have defined it in the section of Principles of Mechanics, we have:

$$\vec{E}=\frac{1}{4\pi\varepsilon}\int\limits_L\frac{\gamma\mathrm{d}l}{r^2}\vec{u}_r \tag{10.1.43}$$

Let us consider an infinite line (wire) of negligible section, and carrying a linear continuous density charge γ. The goal is then to calculate the electric field and potential at any point M of the space outside this line (wire) in order to know the influences of charges of this line (wire) on the environment by considering the influence of the electric field (if the charges were moving we should also take into account the influence of the magnetic field, which we will do in the section Magnetostatics).

For this, the method is to cut the line (wire) into small elements of line (wire) $\mathrm{d}l$, each element carrying a charge load $\mathrm{d}q$. The electric field generated by the charge load on P at point M located at a distance x and of orthogonal projection H on the line is:

$$\mathrm{d}\vec{E}_P(M)=\frac{1}{4\pi\varepsilon}\frac{\lambda\mathrm{d}l}{x^2}\vec{u}_x \tag{10.1.44}$$

The trick now is to take the symmetric P' of P with respect to H (the orthogonal projection of M on the wire)

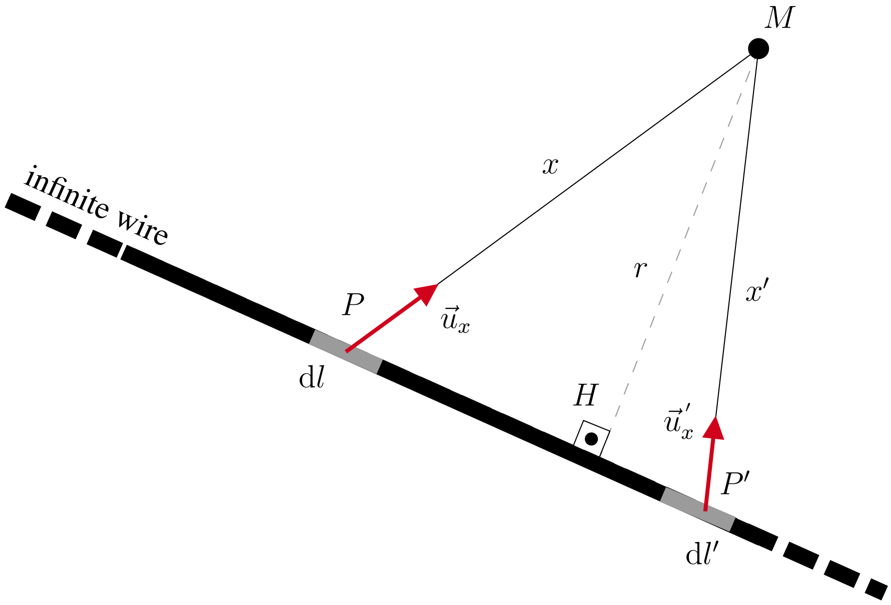

Figure 10.10: Configuration for the analysis of the electric field of an infinite straight wire

for which we have identically:

$$\mathrm{d}\vec{E}_{p'}(M)=\frac{1}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l'}{x'^2}\vec{u}_x \qquad (10.1.45)$$

The total field is therefore:

$$\mathrm{d}\vec{E}(M)=\mathrm{d}\vec{E}_P(M)+\mathrm{d}\vec{E}_{P'}(M)=\frac{1}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^2}\vec{u}_x+\frac{1}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l'}{x'^2}\vec{u}_{x'} \qquad (10.1.46)$$

But we have:

$$x=x' \quad \mathrm{d}l=\mathrm{d}l' \quad \vec{u}_x=\frac{\overrightarrow{PM}}{\overline{\overline{PM}}} \quad \vec{u}_{x'}=\frac{\overrightarrow{P'M}}{\overline{\overline{P'M}}} \qquad (10.1.47)$$

Therefore:

$$\mathrm{d}\vec{E}(M)=\frac{1}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^2}\left(\frac{\overrightarrow{PM}}{\overline{\overline{PM}}}+\frac{\overrightarrow{P'M}}{\overline{\overline{P'M}}}\right)=\frac{1}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^3}\left(\overrightarrow{PM}+\overrightarrow{P'M}\right)=\frac{2}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^3}\overrightarrow{HM} \qquad (10.1.48)$$

As we might expect, the latter relation shows that the field is perpendicular to the line (to the wire...). The norm of $\mathrm{d}\vec{E}(M)$ is:

$$||\mathrm{d}\vec{E}(M)||=\frac{2}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^3}\|\overrightarrow{HM}\|=\frac{2}{4\pi\varepsilon}\frac{\gamma \mathrm{d}l}{x^3}r \qquad (10.1.49)$$

This relation has three dependent variables r, $\mathrm{d}l$, x. The norm of the total field on a point is equal to the sum of the norms of all the vectors $\mathrm{d}\vec{E}(M)$ of the entire length of the wire since all vectors have the same direction.

For this calculation, we will make a change of variable, and put r, $\mathrm{d}l$, x according to the angle α between the line (wire) and the vector $\overrightarrow{PM}$. In the rectangle triangle HMP:

$$\cos(\alpha)=\frac{\overline{HP}}{\overline{\overline{PM}}}=\frac{z}{x} \qquad (10.1.50)$$

if we take the origin of z in H. We also have:

$$\sin(\alpha)=\frac{\overline{HM}}{\overline{PM}}=\frac{r}{x}\qquad \tan(\alpha)=\frac{\overline{HM}}{\overline{HP}}=\frac{r}{z}\tag{10.1.51}$$

and:

$$\mathrm{d}l=\mathrm{d}z=-r\frac{(1+\tan^2(\alpha))}{\tan^2(\alpha)}\mathrm{d}\alpha=-r\frac{\left(1+\dfrac{\sin^2(\alpha)}{\cos^2(\alpha)}\right)}{\dfrac{\sin^2(\alpha)}{\cos^2(\alpha)}}\mathrm{d}\alpha=-r\frac{sin^2(\alpha)+\cos^2(\alpha)}{\sin^2(\alpha)}\mathrm{d}\alpha=\frac{-r}{\sin^2(\alpha)}\mathrm{d}\alpha\tag{10.1.52}$$

therefore:

$$\mathrm{d}E=-\frac{\gamma}{2\pi\varepsilon}\frac{r}{\sin^2(\alpha)}\mathrm{d}\alpha\frac{\sin^3(\alpha)}{r^3}r=-\frac{\gamma}{2\pi\varepsilon r}\sin(\alpha)\mathrm{d}\alpha\tag{10.1.53}$$

$$E=\frac{\gamma}{2\pi\varepsilon r}\cos(\alpha)|_0^{\pi/2}\tag{10.1.54}$$

and therefore:

$$\vec{E}=-\frac{\gamma}{2\pi\varepsilon r}\vec{u}_r\tag{10.1.55}$$

The potential is easily deduced by taking the primitive of E since:

$$\vec{E}=-\begin{pmatrix}\dfrac{\partial}{\partial x}\\ \dfrac{\partial}{\partial y}\\ \dfrac{\partial}{\partial z}\end{pmatrix}\cdot U\tag{10.1.56}$$

Then we have:

$$U=\frac{\gamma}{2\pi\varepsilon}\ln(r)+c^{te}\tag{10.1.57}$$

The constant is undetermined since as r approaches infinity, U tends therefore to zero and leads to an infinite constant. This uncertainty is mainly due to the approximation of the infinite wire length.

10.1.3.2 Electric Rigid Dipole

An important and interesting disposition of electric charges is that forming an "electric dipole" rigorously named "rigid electric dipole" or "electrostatic dipole". It consists of two equal and opposite electric charges $+q,-q$ separated by a very small distance.

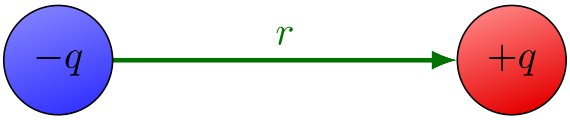

Figure 10.11: **Naive illustration of an electric dipole (author: Izaak Neutelings)**

We will seek to determine the potential and the electric field at a point M of the dipole environment.

To determine this let us consider an electric charge q_i on a point A_i and a very distant point M from A_i. Let us take a Galilean reference frame in O:

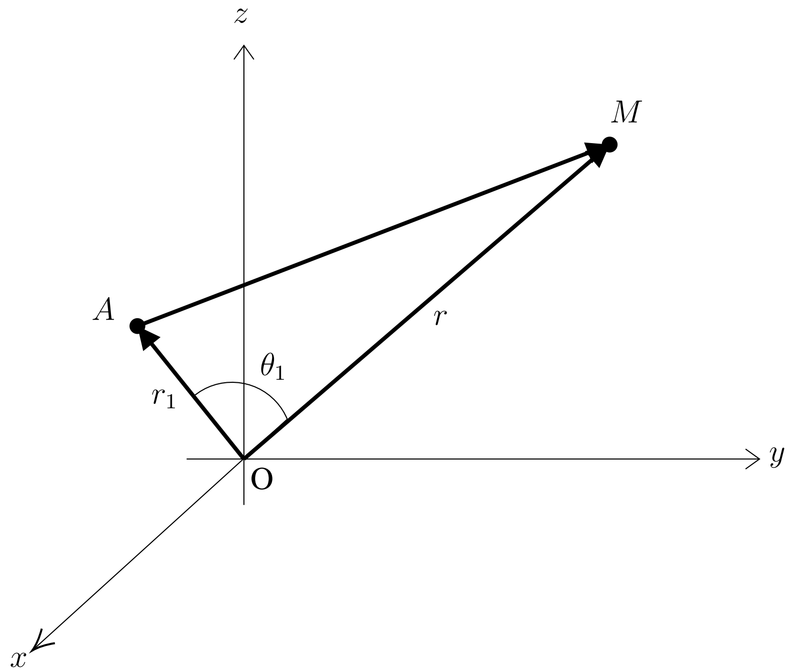

Figure 10.12: **Electric field at a distant point M of the dipole**

The electric potential generated at the M by the charge q_i is:

$$U_i(M)=\frac{1}{4\pi\varepsilon}\frac{q_i}{\overline{A_iM}} \quad (10.1.58)$$

In the triangle OA_iM, the distance $\overline{A_iM}$ can be written with the cosine theorem:

$$\overline{A_iM}=\sqrt{r_i^2+r^2-2r_ir\cos(\theta_i)} \quad (10.1.59)$$

The potential becomes:

$$U_i(M)=\frac{1}{4\pi\varepsilon}\frac{q_i}{\sqrt{r_i^2+r^2-2r_ir\cos(\theta_i)}} \quad (10.1.60)$$

At great distance, r becomes much higher than r_i, the quantity:

$$u=\frac{r_i^2}{r^2}-\frac{2r_i\cos(\theta_i)}{r} \quad (10.1.61)$$

tends to zero. So we can make a Maclaurin development (see section Sequences and Series page 1703) of $(1+u)^{-1/2}$ at the neighbourhood of $u=0$. To avoid making heavy calculations, we will limited ourselves to the order two on r:

$$(1+u)^{-1/2}=1-\frac{1}{2}u-\frac{1}{2}\left(-\frac{3}{2}u^2\right)\frac{1}{2!}=1-\frac{1}{2}u+\frac{3}{8}u^2 \quad (10.1.62)$$

therefore:

$$I=\left(1+\frac{r_i^2}{r^2}-\frac{2r_i\cos(\theta_i)}{r}\right)^{-1/2}\cong 1-\frac{1}{2}\left(\frac{r_i^2}{r^2}-\frac{2r_i\cos(\theta_i)}{r}\right)+\frac{3}{8}\left(\frac{r_i^2}{r^2}-\frac{2r_i\cos(\theta_i)}{r}\right)^2 \tag{10.1.63}$$

Keeping only the terms of the second order in r:

$$I=1-\frac{1}{2}\frac{r_i^2}{r^2}+\frac{r_i\cos(\theta_i)}{r}+\frac{3}{2}\frac{r_i^2\cos^2(\theta_i)}{r^2} \tag{10.1.64}$$

The potential becomes:

$$\begin{aligned}U_i(M)&=\frac{1}{4\pi\varepsilon}\frac{q_i}{r}\left(1-\frac{1}{2}\frac{r_i^2}{r^2}+\frac{r_i\cos(\theta_i)}{r}+\frac{3}{2}\frac{r_i^2\cos^2(\theta_i)}{r^2}\right)\\&=\frac{1}{4\pi\varepsilon}\frac{q_i}{r}+\frac{1}{4\pi\varepsilon}\frac{q_ir_i\cos(\theta_i)}{r^2}+\frac{1}{4\pi\varepsilon}\frac{q_ir_i^2}{r^3}\left(-\frac{1}{2}+\frac{3}{2}\cos^2(\theta_i)\right)=U_i^0+U_i^1+U_i^2\end{aligned} \tag{10.1.65}$$

We kept in the expression of the potential three terms. The term U_i^0 is the potential generated by a charge that would be in O. In other words, at the zero order, the potential generated by a charge located at a point near O is identical to the potential generated by a charge that would be in O. The terms U_i^1,U_i^2 are correction terms, at the first order and second order respectively. We notice that these terms vary on $1/r^2$ and $1/r^3$, thus decreasing faster than the first. These two terms are thus more effective at smaller distances. We see that the terms U_i^1,U_i^2 involve the quantity q_ir_i. This quantity is what we define as the "dipole moment" of the electric rigid dipole:

$$\boxed{\vec{p}_i=q_i\vec{r}_i} \tag{10.1.66}$$

Remark

The dipole moment is expressed in Coulomb meter, but for convenience (...) it is expressed in Debye [D] by some engineers.

The potential generated at great distance by a discrete charge distribution is obtained by summing all individual contributions:

$$U(M)=\sum_i U_i(M)=\frac{1}{4\pi\varepsilon}\frac{1}{r}\sum_i q_i+\frac{1}{4\pi\varepsilon}\frac{1}{r^2}\sum_i q_ir_i\cos(\theta_i)+\frac{1}{4\pi\varepsilon}\sum_i\frac{q_ir_i^2}{r^3}\left(-\frac{1}{2}+\frac{3}{2}\cos^2(\theta_i)\right) \tag{10.1.67}$$

Which can also be written:

$$U(M)=U_0(M)+U_1(M)+U_2(M) \tag{10.1.68}$$

By definition, $U_0(M)$ is unipolar or monopolar term, $U_1(M)$ is the dipolar term, $U_2(M)$ is the quadrupolar term. If the electric charge distribution is a globally zero, as is the case of an ideal atom or of an ideal non-ionized molecule, it only remain the multipolar contributions.

Let us return to the particular case of the dipole:

The term monopolar term is zero, since the sum of the electric charges is zero. If we neglect the terms higher than the first order, there remain the dipole contribution.

The angles θ_1 and θ_2 of the dipole are complementary, therefore $\cos(\theta_1) = -\cos(\theta_2)$. But as $q_1 = -q_2 = q$, the product $q_i\cos(\theta_i)$ is constant.

If the two charges of the dipole are at a constant distance from each other and equidistant from the origin O. We will put that $r_1 = r_2 = d$.

The potential is therefore reduce to:

$$U(M) = \frac{1}{4\pi\varepsilon}\frac{2qd\cos(\theta)}{r^2} = \frac{1}{4\pi\varepsilon}\frac{qa\cos(\theta)}{r^2} \tag{10.1.69}$$

where a is simply the constant distance between the two electric charges. It is customary in the case of the study of the electric dipole to write the above relation as:

$$U(M) = \frac{1}{4\pi\varepsilon}\frac{\vec{p}\circ\vec{u}_r}{r^2} \tag{10.1.70}$$

where $\vec{p}$ is the definition of the dipolar moment and:

$$\vec{u}_r = \frac{\overrightarrow{\text{O}M}}{\left\|\overrightarrow{\text{O}M}\right\|} \tag{10.1.71}$$

Let us recall now that we proved at the beginning of this section that:

$$\vec{E} = -\vec{\nabla}\cdot U \tag{10.1.72}$$

and as we saw in section of Vector Calculus, the gradient in spherical coordinates leads us to write:

$$\vec{E} = -\vec{\nabla}\cdot U = -\begin{pmatrix} \dfrac{\partial U}{\partial r} \\ \dfrac{1}{r}\dfrac{\partial U}{\partial\theta}\dfrac{1}{r\sin(\theta)}\dfrac{\partial U}{\partial\phi} \end{pmatrix} \tag{10.1.73}$$

therefore:

$$\boxed{E_r = \frac{p\cos(\theta)}{2\pi\varepsilon r^3} \quad E_\theta = \frac{p\sin(\theta)}{4\pi\varepsilon r^3} \quad E_\phi = 0} \tag{10.1.74}$$

To determine the equation of the equipotential, remember that these lines (or "surfaces" when in space) are obtained through by the constraint:

$$U = c^{te} := U_0 \tag{10.1.75}$$

Therefore:

$$U = U_0 \Leftrightarrow \frac{p\cos(\theta)}{4\pi\varepsilon r^2} = U_0 \Leftrightarrow r = \sqrt{\frac{p\cos(\theta)}{4\pi\varepsilon U_0}} = r_0\sqrt{\cos(\theta)} \tag{10.1.76}$$

with:

$$r_0 = \sqrt{\frac{p}{4\pi\varepsilon U_0}} \tag{10.1.77}$$

The electric field must by definition be tangential to the field lines, thus parallel to the elementary displacement:

$$\vec{E}\times \mathrm{d}\vec{r}=\vec{0}\Leftrightarrow \begin{pmatrix}E_r\\E_\theta\\E_\phi\end{pmatrix}\times\begin{pmatrix}\mathrm{d}r\\r\mathrm{d}\theta\\r\sin(\theta)\mathrm{d}\phi\end{pmatrix}=\begin{pmatrix}E_r\\E_\theta\\E_\phi\end{pmatrix}\times\begin{pmatrix}\mathrm{d}r\\r\mathrm{d}\theta\\r\sin(\theta)\mathrm{d}\phi\end{pmatrix}=\begin{pmatrix}E_\theta r\sin(\theta)\mathrm{d}\phi-E_\phi r\mathrm{d}\theta\\E_\phi\mathrm{d}r-E_r r\sin(\theta)\mathrm{d}\phi\\E_r r\mathrm{d}\theta-E_\theta\mathrm{d}r\end{pmatrix}=\vec{0} \quad (10.1.78)$$

Since $E_\phi=0$, we have:

$$\vec{E}\times \mathrm{d}\vec{r}=\vec{0}\Leftrightarrow \begin{pmatrix}E_r\\E_\theta\\E_\phi\end{pmatrix}\times\begin{pmatrix}\mathrm{d}r\\r\mathrm{d}\theta\\r\sin(\theta)\mathrm{d}\phi\end{pmatrix}=\begin{pmatrix}E_r\\E_\theta\\E_\phi\end{pmatrix}\times\begin{pmatrix}\mathrm{d}r\\r\mathrm{d}\theta\\r\sin(\theta)\mathrm{d}\phi\end{pmatrix}=\begin{pmatrix}E_\theta r\sin(\theta)\mathrm{d}\phi\\-E_r r\sin(\theta)\mathrm{d}\phi\\E_r r\mathrm{d}\theta-E_\theta\mathrm{d}r\end{pmatrix}=\vec{0} \quad (10.1.79)$$

So finally there remains only:

$$E_r r\mathrm{d}\theta-E_\theta\mathrm{d}r=0\Leftrightarrow E_r r\mathrm{d}\theta=E_\theta\mathrm{d}r \quad (10.1.80)$$

Which is a differential equation that can be easily integrate:

$$\frac{\mathrm{d}r}{r}=\frac{E_r}{E_\theta}\mathrm{d}\theta=2\frac{\cos(\theta)\mathrm{d}\theta}{\sin(\theta)}=2\frac{\mathrm{d}\theta}{\sin(\theta)}\Leftrightarrow\ln(r)=\ln(\sin^2(\theta))+c^{te} \quad (10.1.81)$$

Which is equivalent to write:

$$r=c^{te}\sin^2(\theta) \quad (10.1.82)$$

The plot of the field and equipotential lines then gives in spherical coordinates (remember that the vertical component is zero by symmetry):

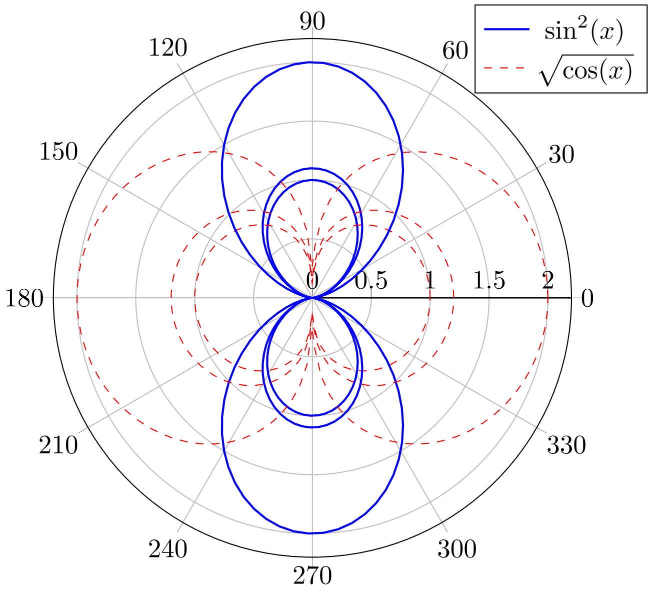

Figure 10.13: **Polar plot of the field lines and equipotentials of an electric dipole**

Even if in an electric dipole the two charges are equal and opposite, giving a zero net charge, the fact they are slightly displaced is sufficient to produce a non identically zero electric field.

In atoms, the center of mass of the electrons coincides with the core, and therefore the average electric dipole moment of the atom is zero. But if an external field is applied, the movement of electrons is distorted and the electron mass center is displaced by a given distance from the core. The atom is then polarised and becomes an electric dipole of moment $\vec{p}$. This moment is proportional to the external applied field $\vec{E}$.

As we did not found in Maple™ 17.00 how to do the polar plot above here is another Maple™ 17.00 code to have fun with a dipole:

```
>V:=1/sqrt((x-1)^2+y^2+z^2)-2/sqrt((x+1)^2+y^2+z^2):
>with(LinearAlgebra); with(VectorCalculus); with(plots);
>with(plottools);
>Efield := Gradient(-V, [x, y, z]);
>fieldplot3d([Efield[1], Efield[2], Efield[3]],x =-1.5..1.5, y
=-1.5..1.5, z =-1.5..1.5);
>NormEfield := Normalize(Efield,2);
>p1:=sphere([1, 0, 0],0.75,color=red);
>p2:=sphere([-1, 0, 0],1.5,color=blue);
>p3:=fieldplot3d(NormEfield,x=-4.5..4.5,y=-4.5..4.5,z
=-4.5..4.5,color=black);
>display([p1, p2, p3], scaling = constrained);
```

Giving at first (obviously the dimensions are fictitious):

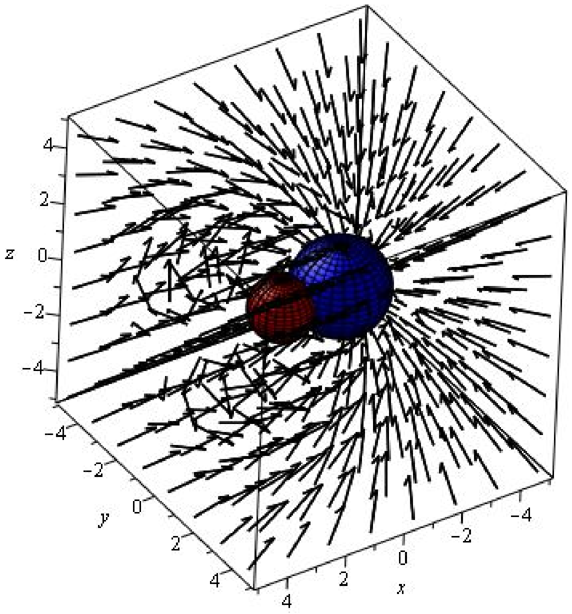

Figure 10.14: **Electric field lines for two charges of opposite signs in Maple™ 17.00**

Or to get the view of the potential with the equipotentials:

```
>z:= 0;
>plot3d(V,x =-1.5..1.5, y=-1.5..1.5, style=patchcontour,contours=200);
```

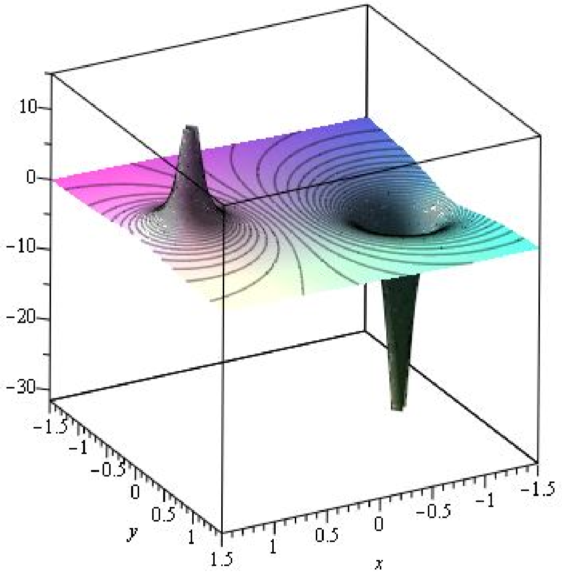

Figure 10.15: **Potential well and equipotentials of the dipole in Maple™ 17.00**

Or to get a 2D profile of the electric field and equipotentials:

```
>p4:=implicitplot(seq(V=(1/10)*b,b=-10..10),x=-5..5,y=-4..4);
>p5:=fieldplot([NormEfield[1],NormEfield[2]],x=-5 ..  5,y=-4..4);
>display([p4, p5], scaling = constrained);
```

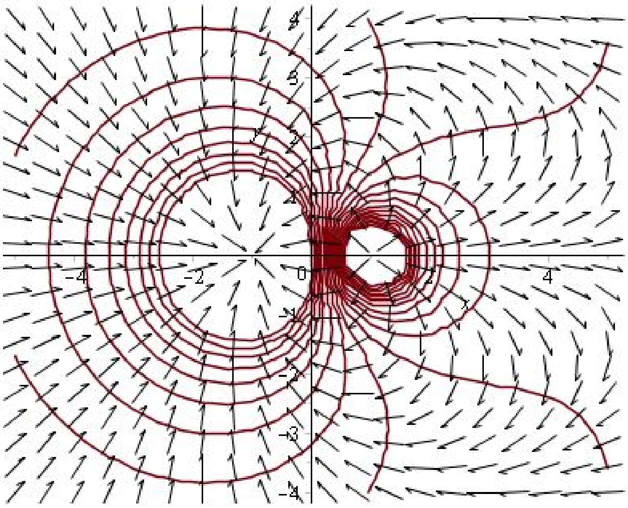

Figure 10.16: **2D profile of electric field and potential of the dipole in Maple™ 17.00**

Remark

Molecules also may have a permanent electric moment. Such molecules are named "polar molecules" For example, in the HCl molecule the electron of the hydrogen atom spends more time to move around the chlorine that around the hydrogen atom. Also, the center of negative charges does he not coincide with that of the positive charge of the center and the molecule has a dipole moment. By cons, in the molecule CO_2, all the atoms are aligned, and the resulting electric dipole moment is zero for reasons of symmetry.

When an electric dipole is positioned in an electric field, a force is exerted on each of the charges of the dipole. The resulting force is:

$$\vec{F}=q\vec{E}_{+}-q\vec{E}_{-}=q(\vec{E}_{+}-\vec{E}_{-}) \tag{10.1.83}$$

Let us consider the particular case where the electric field is directed along the x-axis and where the dipole is oriented parallel to this field.

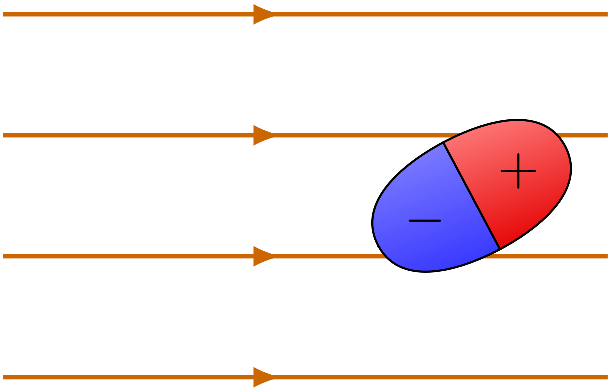

Figure 10.17: **Naive illustration of an electric dipole in a uniform electric field (author: Izaak Neutelings)**

If we only consider the quantities:

$$\vec{E}_{+}-\vec{E}_{-}=\left(\frac{\mathrm{d}E}{\mathrm{d}x}\right)a \tag{10.1.84}$$

with a being the distance between the two charges, and therefore: dipole is oriented parallel to this field. If we only consider the quantities:

$$F=q\frac{\mathrm{d}E}{\mathrm{d}x}a=p\frac{\mathrm{d}E}{\mathrm{d}x} \tag{10.1.85}$$

This result show that an electric dipole oriented parallel to the field tends to move in the direction in which the field increases (as the gradient thereof). We note that if the electric field is uniform, the resultant force on the dipole is zero!!!

The potential energy of the dipole is:

$$E_P=qU_{+}-qU_{-}=q(U_{+}-U_{-})=-qa\left(-\frac{U_{+}-U_{-}}{a}\right) \tag{10.1.86}$$

If we use the equation:

$$\vec{E}=-\vec{\nabla}\cdot U \tag{10.1.87}$$

to describe the uniform electric field and if θ is the angle between the dipole and the electric field, the last factor $(U_{+}-U_{-})/a$ is just the component $E_a=E\cos(\theta)$ of the field $\vec{E}$ parallel to a. So:

$$E_P=-qaE_a \tag{10.1.88}$$

or:

$$E_P = -pE\cos(\theta) = -\vec{p} \circ \vec{E} \tag{10.1.89}$$

The potential energy is minimum for $\theta = 0$, which shows that the dipole is in equilibrium when it is oriented parallel to the field.

These configurations of a dipole placed in an electric field have very important applications. For example, the electric field of an ion in a solution polarized the solvent molecules that surround the ions and they are oriented as in the figure below:

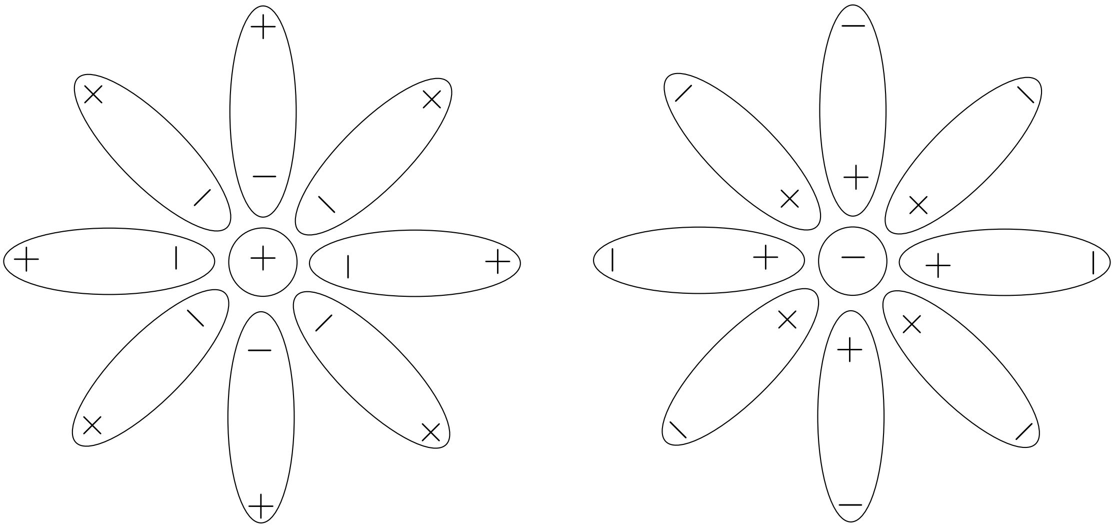

Figure 10.18: Example of what happens in a solution with an ion

In a solvent with polar molecules such as water, ions of an electrolyte in solution are surrounded by a number of these molecules due to the dipole-charge interaction. This phenomenon is named "solvation" of the ion, specifically "hydration" if the solvent is water.

For example with Salz (NaCl):

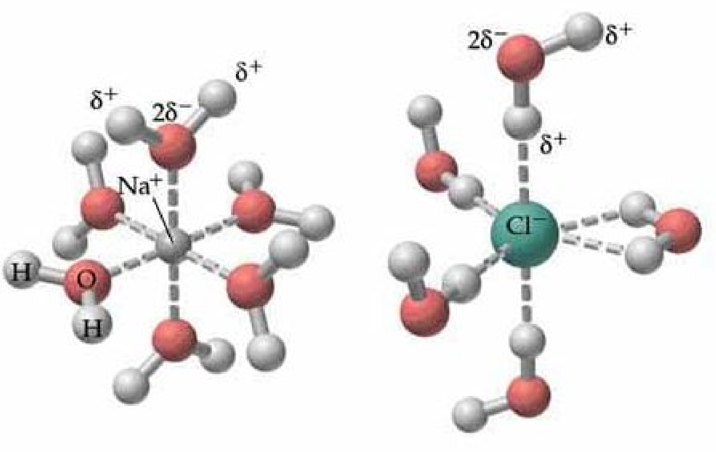

Figure 10.19: Hydration of salz (source: ?)

These oriented molecules become more or less dependant of the ion, increasing its effective mass and decreasing its effective charge, which is partially obscured by the molecules (screening). The net effect is that the mobility of a ion in an external field is reduced. Similarly, when a gas or liquid, which molecules are permanent dipoles is placed in an electric field, the molecules as a result of the force couple applied due to the electric field, tend to align with their dipoles parallel. We then say that the substance was "polarized".

It may therefore be interesting to determine the vector electric field produced by a dipole rather than its potential. The electrostatic field generated at a point M by the doublet is obtained by performing the vector sum of the fields generated in this point by positive P and negative N charges, hence:

$$\vec{E}=\vec{E}_P+\vec{E}_N=\frac{q}{4\pi\varepsilon}\left(\frac{\overrightarrow{PM}}{\left\|\overrightarrow{PM}\right\|^3}+\frac{\overrightarrow{NM}}{\left\|\overrightarrow{NM}\right\|^3}\right)=\frac{q}{4\pi\varepsilon}\left(\frac{\vec{r}-a\dfrac{\vec{e}_z}{2}}{\left\|\vec{r}-a\dfrac{\vec{e}_z}{2}\right\|^2}-\frac{\vec{r}+a\dfrac{\vec{e}_z}{2}}{\left\|\vec{r}+a\dfrac{\vec{e}_z}{2}\right\|^2}\right)$$
$$=\frac{q}{4\pi\varepsilon}\left(\left(\vec{r}-\frac{a}{2}\vec{e}_z\right)\left\|\vec{r}-a\frac{\vec{e}_z}{2}\right\|^{-3}-\left(\vec{r}+\frac{a}{2}\vec{e}_z\right)\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^{-3}\right) \tag{10.1.90}$$

The distribution of charges being invariant by rotation about the z axis of the doublet, the topography is independent of the azimuthal angle π of the spherical coordinates. We can then represent it in any meridian plane passing through the axis NP. The field $\vec{E}$ is the given by:

$$\vec{E}=\frac{q}{4\pi\varepsilon}\left(\left(\vec{r}-\frac{a}{2}\vec{e}_z\right)\left\|\vec{r}-a\frac{\vec{e}_z}{2}\right\|^{-3}-\left(\vec{r}+\frac{a}{2}\vec{e}_z\right)\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^{-3}\right) \tag{10.1.91}$$

Having:

$$\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^3=\left(\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^2\right)^{3/2} \tag{10.1.92}$$

vectorially, we get:

$$\vec{r}+\frac{a}{2}\vec{e}_z=\begin{pmatrix} r_x \\ r_y \\ r_z+\dfrac{a}{2}\end{pmatrix}\Rightarrow\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^2=\underbrace{r_x^2+r_y^2+r_z^2}_{r^2}+2r_z\frac{a}{2}+\frac{a^2}{4}=r^2+ar_z+\frac{a^2}{4} \tag{10.1.93}$$

The dot product being the multiplication of components one by one, we have:

$$\vec{r}\circ\vec{e}_z=r_z \tag{10.1.94}$$

Hence:

$$\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^2=r^2+a\vec{r}\circ\vec{e}_z+\frac{a^2}{4} \tag{10.1.95}$$

Finally:

$$\left(\left\|\vec{r}+a\frac{\vec{e}_z}{2}\right\|^2\right)^{3/2}=\left(r^2+a\vec{r}\circ\vec{e}_z+\frac{a^2}{4}\right)^{3/2}=r^3\left(1+a\frac{\vec{r}\circ\vec{e}_z}{r^2}+\frac{a^2}{4r^2}\right)^{3/2} \tag{10.1.96}$$

So by a limited Maclaurin series development as we did at the beginning:

$$\begin{aligned}\vec{E}&=\frac{q}{4\pi\varepsilon r^3}\left(\left(\vec{r}-\frac{a}{2}\vec{e}_z\right)\left[1-a\frac{\vec{r}\circ\vec{e}_z}{r^2}+\frac{a^2}{4r^2}\right]^{-3/2}-\left(\vec{r}+\frac{a}{2}\vec{e}_z\right)\left[1+a\frac{\vec{r}\circ\vec{e}_z}{r^2}+\frac{a^2}{4r^2}\right]^{-3/2}\right)\\&\cong\frac{q}{4\pi\varepsilon r^3}\left(\left(\vec{r}-\frac{a}{2}\vec{e}_z\right)\left[1+\frac{3}{2}a\frac{\vec{r}\circ\vec{e}_z}{r^2}+\ldots\right]-\left(\vec{r}+\frac{a}{2}\vec{e}_z\right)[]\left[1-\frac{3}{2}a\frac{\vec{r}\circ\vec{e}_z}{r^2}+\ldots\right]\right)\\&=-\frac{q}{4\pi\varepsilon r^3}a\vec{e}_z+\frac{3q\vec{r}}{4\pi\varepsilon r^5}a\vec{r}\circ\vec{e}_z+\ldots\cong\frac{1}{4\pi\varepsilon}\left[\frac{3(\vec{p}\circ\vec{r})\cdot\vec{r}}{r^5}-\frac{\vec{p}}{r^3}\right]\end{aligned} \tag{10.1.97}$$

By introducing:

$$\vec{u}_r=\frac{\vec{r}}{\|\vec{r}\|}=\frac{\vec{r}}{r} \tag{10.1.98}$$

We can simplify the notations:

$$\vec{E}\cong\frac{3(\vec{p}\circ\vec{u}_r)\vec{u}_r-\vec{p}}{4\pi\varepsilon r^3} \tag{10.1.99}$$

It may also be relevant to calculate the energy of interaction between two electric dipoles. If we denote by $\vec{p}_1$ the dipole moment, we can write:

$$\vec{E}_1\cong\frac{3(\vec{p}_1\circ\vec{u}_r)\vec{u}_r-\vec{p}_1}{4\pi\varepsilon r^3} \tag{10.1.100}$$

If we denote by $\vec{p}_2$ the moment of the second dipole and if we use the relation:

$$E_p=-\vec{p}\circ\vec{E} \tag{10.1.101}$$

we find that the interaction energy between two dipoles is:

$$E_{P,1,2}=-\vec{p}_2\circ\vec{E}_1-\frac{3((\vec{p}_1\circ\vec{u}_r)\vec{u}_r)\circ cp_2-\vec{p}_1\circ\vec{p}_2}{4\pi\varepsilon r^3} \tag{10.1.102}$$

We can draw out several important conclusions from this result. The energy of interaction $E_{P,1,2}$ is symmetric relatively to the two dipoles, because the permutation of $\vec{p}_1$ and of $\vec{p}_2$ leaves it unchanged. This is an expected result. The interaction between two dipoles is not central as it depends of the angles which the vector position or the unitary vector $\vec{u}_r$ do with $\vec{p}_1$ and $\vec{p}_2$.

An atom, molecule or a ion, whose dipole moment is zero in the fundamental state, acquire a dipole moment under the action of the applied non-uniform electric field as we have seen since the opposing signs charges are solicited in opposed directions. The centers of gravity of positive and negative charges do not coincide anymore, it appears an "induced dipole moment".

In an experiment with linear approximation for weak excitatory electric fields, the induced dipole moment is proportional to the applied field $\vec{E}$, which we translate by (it is in fact an approximation of the Langevin-Debye relation we will prove later):

$$\vec{p}=\alpha\varepsilon\vec{E} \tag{10.1.103}$$

The quantity α, which physical dimension is that of a volume is the "polarizability" of the structure. The dipole-dipole electrostatic interaction was introduced by J.D. Van der Waals in 1873, in the case of molecules, to interpret real deviations from the ideal gas.

The Van der Waals forces are repulsive as the distance between molecules is very low because they oppose the interpenetration of electron clouds, what we express by introducing their volume (covolume).

By cons, they are attractive when the distance is sufficient. We attribute this attraction to three types of interactions involving rigid or induced dipoles:

1. The forces between polar molecules (rigid dipoles), say to be "Keesom forces".
2. The forces between a polar molecule (rigid dipole) and a polarizable molecule (induced dipole) named "Debye forces".
3. The average forces between induced dipoles which appear even when the molecules are not polar, named "London forces".

In all these three cases, the electrostatic energy is negative (attraction) and varies as r^{-6}. To prove this statement, let us calculate the interaction energy between two rigid dipoles, of dipolar moments $\vec{p}_1$ and $\vec{p}_2$:

$$E_{P,2,1}=-\vec{p}_1\circ\vec{E}_2 \tag{10.1.104}$$

with:

$$\vec{E}_2\cong\frac{3(\vec{p}_2\circ\vec{u}_r)\vec{u}_r-\vec{p}_2}{4\pi\varepsilon r^3} \tag{10.1.105}$$

and:

$$\vec{p}_1=\alpha\varepsilon\vec{E}_2 \tag{10.1.106}$$

Therefore:

$$\vec{E}_2=-\alpha\varepsilon\vec{E}_2\circ\vec{E}_2=-\alpha\varepsilon E_2^2\cong-\alpha\varepsilon\left(\frac{2p_2}{4\pi\varepsilon r^3}\right)^2=-\frac{c^{te}}{r^6}=-\frac{C_6}{r^6} \tag{10.1.107}$$

This is the van der Waals interaction potential between two dipoles atoms where C_6 is the "Van der Waals constant".

Hence:

$$\vec{F}=-\vec{\nabla}\cdot E_P=\frac{\overrightarrow{C^{te}}}{r^7} \tag{10.1.108}$$

Thus, the radial dependence of the force is indeed in r^{-7}. This very rapid decay of the Van der Waals force with distance helps explain its very short range and therefore its influence when the medium is sufficiently dense. However the decay is slower than the chemical bond that decrease exponentially (see section Quantum Chemistry page 6190).

Remark

The interaction between polar molecules, of the Keesom type, is made very high in the presence of hydrogen, because the latter, thanks to its small size, also interacts with the atoms of other molecules. It is that one which is at the origin of the "hydrogen bonding".

10.1.4 Electric Flux

Given $\vec{V}$ a vector field and S a surface named "Gauss surface" in space. If we divide this area into a number N of smaller surfaces $\mathrm{d}S$ each traversed by a field $\vec{V}_i$ and having a unit perpendicular vector $\vec{n}_i$ (special case) on their surface, then we can form the sum of:

$$\sum_{i=1}^{N} \vec{V}_i \circ \vec{n}_i \mathrm{d}S \tag{10.1.109}$$

When N tends to infinity and all $\mathrm{d}S$ to zero, we get for this sum:

$$\Phi_V = \int_{\Sigma} \vec{V}_i \circ \mathrm{d}\vec{S} \tag{10.1.110}$$

The value of this integral thus gives the flow Φ_V of the field $\vec{V}$ through the surface S delimited by a domain Λ and where:

$$\mathrm{d}\vec{S} = \vec{n}\mathrm{d}S \tag{10.1.111}$$

In the case of the electrostatic field, we write:

$$\boxed{\Phi_E = \int_{\Sigma} \vec{E} \circ \mathrm{d}\vec{S}} \tag{10.1.112}$$

This expression, define the "electric flow" or also named "electric flux".

The inevitable question that arises is then: what is its physical meaning? The flux of a fluid is the amount of fluid (especially the quantity of volume) passing through a surface by second. Then there is a flux (flow) of something. About the electrical flux (flow), from the classical point of view, nothing flows, the electric field is already established and is static, but is flow through the surface. The value of the electric field at any point in space is the field intensity at that point, while the flow can be considered the quantity of field which passes through the surface S.

There is a hundred years, physicists identified the flow with the number of electric field lines passing through the surface. But the least we can say is that the simplistic view that the field lines have a distinct reality and that we can count is misleading. We will see during our study of Quantum Field Theory, in the section of the same name, that the latter supports a virtual photons current that is the nature of electromagnetic interactions. Despite this, the physicists did not hurry to associate the flow of virtual photons of the 120th century (holocene calendar) to the continuous electric field lines of the 119th century. Whatever its nature, the concept of flow is powerful and of great practical use, both in electricity and magnetism.

As will we prove it in the framework of Maxwell's equations (see section Electrodynamics page 4095), solving this integral gives in the general case (this is the "Gauss law for electrostatic" also named "Gauss theorem for electrostatic"):

$$\boxed{\Phi_E=\oint\limits_{\Sigma}\vec{E}\circ\mathrm{d}\vec{S}=\frac{Q}{\varepsilon}=\frac{\sum_i q_i}{\varepsilon}} \tag{10.1.113}$$

In the case where the surface is not closed and reduce to a plane, the previous close surface integral is reduced to:

$$\Phi_E=\vec{E}\circ\vec{S}=ES\cos(\alpha) \tag{10.1.114}$$

10.1.4.1 Capacitor

A capacitor (originally known as a condenser) is a passive two-terminal electrical component used to store electrical energy temporarily in an electric field. The forms of practical capacitors vary widely, but all contain at least two electrical conductors (plates) separated by a dielectric (i.e. an insulator that can store energy by becoming polarized). The conductors can be thin films, foils or sintered beads of metal or conductive electrolyte, etc. The non-conducting dielectric acts to increase the capacitor's charge capacity. Materials commonly used as dielectrics include glass, ceramic, plastic film, air, vacuum, paper, mica, and oxide layers. Capacitors are widely used as parts of electrical circuits in many common electrical devices. Unlike a resistor, an ideal capacitor does not dissipate energy. Instead, a capacitor stores energy in the form of an electrostatic field between its plates.

When there is a potential difference across the conductors (e.g., when a capacitor is attached across a battery), an electric field develops across the dielectric, causing positive charge $+Q$ to collect on one plate and negative charge $-Q$ to collect on the other plate. If a battery has been attached to a capacitor for a sufficient amount of time, no current can flow through the capacitor. However, if a time-varying voltage is applied across the leads of the capacitor, a displacement current can flow.

An ideal capacitor is characterized by a single constant value, its capacitance (in practice we can see a voltage rating on any capacitor that is the maximum amount of voltage that a capacitor can safely be exposed to and can store). Capacitance is defined as the ratio of the electric charge Q on each conductor to the potential difference U between them. The SI unit of capacitance is the farad [F], which is equal to one coulomb per volt (1 [C·V^{-1}]). Typical capacitance values range from about 1 [pF] to about 1 [mF], but "super capacitors" of a few centimetres in 12021 (holocene calendar) can store $30,000$ [F].

The larger the surface area of the "plates" (conductors) and the narrower the gap between them, the greater the capacitance is. In practice, the dielectric between the plates passes a small amount of leakage current and also has an electric field strength limit, known as the breakdown voltage. The conductors and leads introduce an undesired inductance and resistance.

Capacitors are widely used in electronic circuits for blocking direct current while allowing alternating current to pass. In analogue filter networks, they smooth the output of power supplies. In resonant circuits they tune radios to particular frequencies. In electric power transmission systems, they stabilize voltage and power flow.

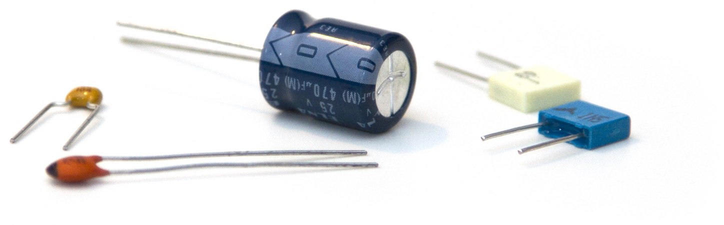

Figure 10.20: **Some capacitive dipoles**
(source: `http://www.e-style.ch`, author: Martin Bircher)

As a direct application of Gauss's theorem, very useful in electronics and for engineers, consider a large thin a flat sheet, wearing a homogeneous surfacic electronic charge density σ and immersed in an environment of absolute electrical permittivity ε. In the area close to its center, the electric field resulting from all the fields of the fields is normal, uniform, constant and go away from the sheet. Let us consider a Gaussian surface with a cylinder shape limited by the bases $S_1=S_2=S$ and its tubular surface S_3 symmetrical with respect to the sheet. It therefore encloses an electric charge σS. It follows that:

$$\oint \vec{E}\circ\mathrm{d}\vec{S}=E_1S_1+E_2S_2+E_3S_3=\frac{\sum_i q_i}{\varepsilon} \tag{10.1.115}$$

and as $E=E_1=E_2$ and $E_3=0$, we find:

$$ES+ES=2ES=\frac{Q}{\varepsilon}\Rightarrow E=\frac{Q/S}{2\varepsilon}=\frac{Q/S}{2\varepsilon}=\frac{\sigma}{2\varepsilon} \tag{10.1.116}$$

Finally, the electric field of a large and thin loaded flat sheet is:

$$E=\frac{\sigma}{2\varepsilon} \tag{10.1.117}$$

If we put face to face two identical plates but with opposite charges, the algebraic sum will of course be:

$$E=\frac{\sigma}{\varepsilon} \tag{10.1.118}$$

Excepted of the extremities where the side effect is important, the overall field is everywhere the vector sum of uniform fields from two opposing thin loaded layers. We name such a system a "plane and parallel capacitor":

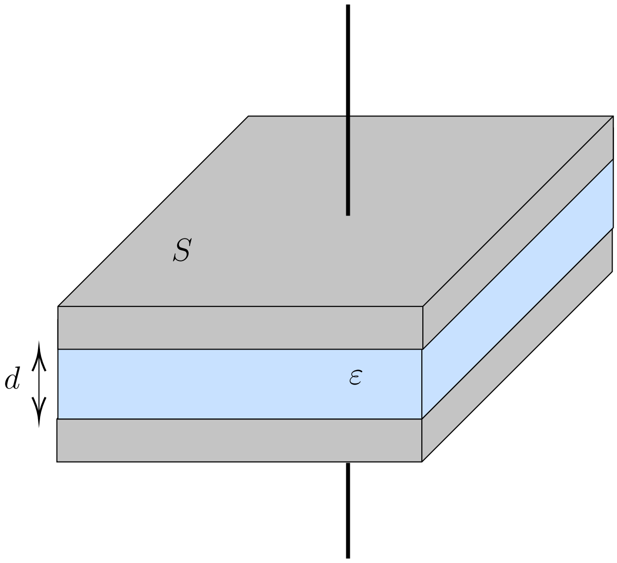

Figure 10.21: **Schematic diagram of plane and parallel capacitor**

The result is remarkable because it is independent of the distance between the planes (in fact never forget it is an approximation for very small distances!). The calculation of electric potential is therefore simplified. Thus:

$$\Delta U=-\int_0^d E\mathrm{d}r=-\frac{\sigma}{\varepsilon}d \Rightarrow U=|\Delta U|=\frac{\sigma d}{\varepsilon}=\frac{Qd}{\varepsilon S} \tag{10.1.119}$$

Thus, the capacitance of the plane and parallel capacitor is consequently:

$$\boxed{C=\frac{Q}{U}=\frac{\varepsilon S}{d}} \tag{10.1.120}$$

Let us now recall that we have shown previously that:

$$E=\frac{\sigma}{2\varepsilon}=\frac{Q}{2S\varepsilon} \tag{10.1.121}$$

Since each plate of a parallel and plane capacitor contributes equally, the total electric field between the plates would be :

$$E_{\text{tot}}=2\frac{Q}{2S\varepsilon}=\frac{Q}{S\varepsilon} \tag{10.1.122}$$

The potential difference is:

$$U=E_{\text{tot}}d=d\frac{Q}{S\varepsilon} \tag{10.1.123}$$

Solving for Q yields:

$$Q=S\varepsilon\frac{U}{d} \tag{10.1.124}$$

The plates are oppositely charged, so the attractive force F_{att} between the two plates is equal to the electric field produced by one of the plates times the charge on the other:

$$\boxed{F_{\text{att}}=Q\frac{Q}{2S\varepsilon}=\frac{\varepsilon SU^2}{2d^2}} \tag{10.1.125}$$

This is therefore the force between the plates of a parallel (infinite) plate capacitor.

Let us see a second academic example that is the "cylindrical capacitor":

The plates of a cylindrical capacitor are two infinite rolled cylinders (or very long relatively to their diameter), coaxial of respective radius R_1 and R_2. It is therefore the very important case of the coaxial cable (which dielectric is often polyethylene) that we can find in many laboratories (and not only!):

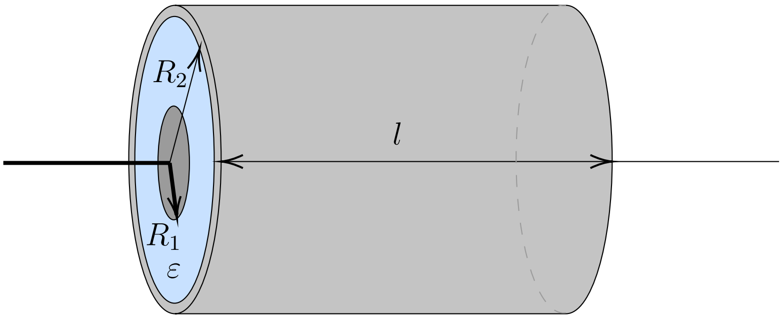

Figure 10.22: Schematic diagram of cylindrical capacitor

By Gauss theorem, we know that:

$$\vec{E}\circ\vec{S}=\frac{Q}{\varepsilon} \tag{10.1.126}$$

And since the field $\vec{E}$ is collinear at every point of the surface $\vec{S}$, it immediately comes by knowing the expression of the surface of the cylinder (see section Geometric Shapes page 2959):

$$E=\frac{Q}{2\pi rl\varepsilon} \tag{10.1.127}$$

But:

$$\begin{aligned}\Delta U&=-\int\limits_{R_1}^{R_2}E\mathrm{d}r=-\int\limits_{R_1}^{R_2}\frac{Q}{2\pi l\varepsilon}\frac{1}{r}\mathrm{d}r=-\frac{Q}{2\pi\varepsilon l}\left[\ln(r)\right]\Big|_{R_1}^{R_2}\\&=-\frac{Q}{2\pi\varepsilon l}\left[\ln(R_2)-\ln(R_1)\right]=-\frac{Q}{2\pi\varepsilon l}\ln\left(\frac{R_2}{R_1}\right)\end{aligned} \tag{10.1.128}$$

Therefore:

$$\boxed{C=\frac{Q}{U}=\frac{Q}{|\Delta U|}=2\pi\varepsilon l\frac{1}{\ln\left(\dfrac{R_2}{R_1}\right)}} \tag{10.1.129}$$

Or often written in the form of the "coaxial capacity per unit length":

$$C=\frac{Q}{U}=\frac{Q}{|\Delta U|}=2\pi\varepsilon\frac{1}{\ln\left(\dfrac{R_2}{R_1}\right)} \tag{10.1.130}$$

Let us also calculate the capacity of a spherical capacitor which corresponds in a first approximation to some of Van Der Graaf generators that we have in the labs of some schools, museums or even research centers...

A "spherical capacitor" consists of two concentric spheres of radius R_1 and R_2 with $R_1 < R_2$.

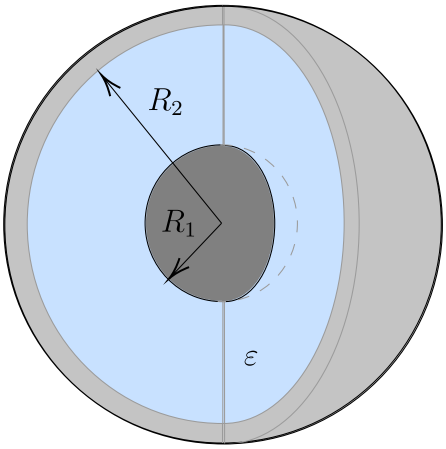

Figure 10.23: Schematic diagram of spherical capacitor

We now have immediately (by Gauss theorem):

$$\vec{E}\circ\vec{S}=\frac{Q}{\varepsilon} \tag{10.1.131}$$

And therefore since the field is assumed to be collinear at any point on the surface it comes immediately knowing the expression of the surface of a sphere:

$$E=\frac{Q}{4\pi r^2\varepsilon} \tag{10.1.132}$$

But:

$$\Delta U=-\int\limits_{R_1}^{R_2} E\mathrm{d}r=-\int\limits_{R_1}^{R_2}\frac{Q}{4\pi\varepsilon}\frac{1}{r^2}\mathrm{d}r=-\frac{Q}{4\pi\varepsilon}\left[\frac{1}{r}\right]\Bigg|_{R_1}^{R_2}=-\frac{Q}{4\pi\varepsilon}\left(\frac{1}{R_2}-\frac{1}{R_1}\right) \tag{10.1.133}$$

Then we have:

$$C=\frac{Q}{U}=\frac{Q}{|\Delta U|}=4\pi\varepsilon\left(\frac{1}{R_2}-\frac{1}{R_1}\right)^{-1} \tag{10.1.134}$$

Then we have:

$$\boxed{C=4\pi\varepsilon\frac{R_1R_2}{R_1-R_2}} \tag{10.1.135}$$

And that's all for the classical examples...

Well! We have just seen that the capacity was defined as:

$$Q=CU \tag{10.1.136}$$

or in alternative current notation (when the current or the voltage varies as function of the time, it is the usage to write them in lowercase):

$$q=Cu\Leftrightarrow\frac{\mathrm{d}q}{\mathrm{d}t}=i=C\frac{\mathrm{d}u}{\mathrm{d}t}\tag{10.1.137}$$

We then have for the instantaneous power (see section Electrokinetics page 4253):

$$p=\Delta ui=ui=(ri-e)i=ri^2-ei\tag{10.1.138}$$

Assuming an ideal capacitor (which does not dissipate energy by Joule effect) we get:

$$p=ui=uC\frac{\mathrm{d}u}{\mathrm{d}t}=Cu\frac{\mathrm{d}u}{\mathrm{d}t}=\frac{\mathrm{d}\left(\dfrac{1}{2}Cu^2\right)}{\mathrm{d}t}\tag{10.1.139}$$

So by integration in a given time interval from 0 to t we have for the second term:

$$E_C=\frac{1}{2}Cu^2\tag{10.1.140}$$

This energy is always positive and is stored in electrostatic form in the capacitor.

In the context of a sine wave alternative current, the average power will be equal to zero. We can generalize this by assuming that a perfect capacitor does not dissipate power no Joule effect.

Remark

Some scientific experiments requiring enormous energy use thousands of giant capacitors charged in the long term to accelerate particles or to make operate megajoules LASER. However we can not actually store the surplus of electric power of some power plants, which is why we use this surplus to pull back the water in the dams that can use their pool as a reserve of potential energy to produce a complement to electricity at the time of peak consumption (inverse transformation). We can also found huge capacitor that have for purpose to manage critical voltage collapse in a changing environment (this are the big cylinder in transformation stations).

Obviously a real capacitor has an internal resistance often depicted as:

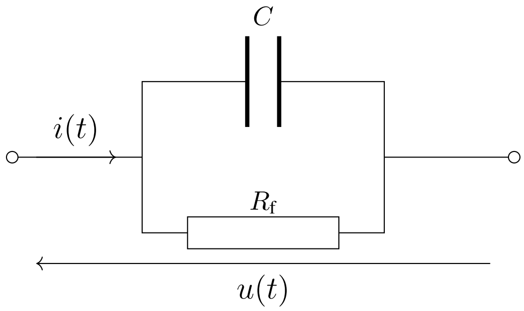

Figure 10.24: **Real capacitor (author: Jimmy Roussel)**

10.1.4.1.1 Dielectric strength

The term "dielectric strength" denoted $\mathcal{R}$ and (measured in SI units volts per meter [V·m^{-2}]) has the following meanings:

- Of an insulating material, the maximum electric field that a pure material can withstand under ideal conditions without breaking down (i.e., without experiencing failure of its insulating properties).
- For a specific configuration of dielectric material and electrodes, the minimum applied electric field (i.e., the applied voltage divided by electrode separation distance) that results in breakdown.

The theoretical dielectric strength of a material is an intrinsic property of the bulk material and is independent of the configuration of the material or the electrodes with which the field is applied. This "intrinsic dielectric strength" corresponds to what would be measured using pure materials under ideal laboratory conditions. At breakdown, the electric field frees bound electrons. If the applied electric field is sufficiently high, free electrons from background radiation may become accelerated to velocities that can liberate additional electrons during collisions with neutral atoms or molecules in a process named "avalanche breakdown". Breakdown occurs quite abruptly (typically in nanoseconds), resulting in the formation of an electrically conductive path and a disruptive discharge through the material. For solid materials, a breakdown event severely degrades, or even destroys, its insulating capability.

The factors affecting apparent dielectric strength are typically:

- it decreases with increased sample thickness.
- it decreases with increased operating temperature.
- it decreases with increased frequency.
- for gases (e.g. nitrogen, sulphur hexafluoride) it normally decreases with increased humidity.
- for air, dielectric strength increases slightly as humidity increases

For a capacitor used in electronics, if we exceed the dielectric strength value, we observe the destruction of the element. This maximum value of the voltage applied to the terminals, is named sometimes the "breakdown voltage" of the capacitor and denoted U_c. We can define the dielectric strength of the material (medium) as:

$$\boxed{\mathcal{R}=\frac{U_c}{d}} \tag{10.1.141}$$

✍**Example:**

Two common dielectric strength values that have to be know by students are:

$$\mathcal{R}_{\text{air}} \cong 3 \cdot 10^9 \;[\text{V} \cdot \text{m}^{-1}] \qquad \mathcal{R}_{\text{vacuum}} \cong 10^{21} \;[\text{V} \cdot \text{m}^{-1}] \tag{10.1.142}$$

When we talk of dielectric strength, we also speak of the dielectric is an insulator or a substance that does not conduct electricity and is polarizable by an electric field. In most cases, the dielectric properties are due to the polarization of the substance. When the dielectric (in this case, air is the dielectric) is placed in an electric field, the electrons and protons of its atoms are reoriented and, in some cases, at the molecular level, a polarization is induced (as we have seen in our study of the dipoles above). This polarization produces a potential difference, or voltage, between both terminals of the dielectric; it then stores the energy which becomes available when the electric field is removed. The effectiveness of a dielectric is its relative ability to store energy compared to that of vacuum. It is expressed by the relative electric permittivity ε_r, determined relative to that of a vacuum ε_0. The dielectric strength is then ability of a dielectric to withstand electric fields without losing its insulating properties. An effective dielectric releases a big fraction of the energy it had stored when the electric field is reversed.

HOW CAPACITOR STORES ENERGY

Energy is stored in the electric field between its plates.

1. CAPACITOR STRUCTURE

A capacitor has two conductors (plates) separated by an insulating material called a dielectric.

- Equal and opposite charge ±Q builds up on the plates.
- The potential difference between the plates is V.

2. CHARGING PROCESS

When a voltage source is connected, electrons flow, placing +Q on one plate and −Q on the other.

Charging continues until the voltage across the capacitor equals V.

3. ELECTRIC FIELD FORMED

Opposite charges create an electric field between the plates.

$$E = \frac{V}{d}$$

E = electric field (V/m)
V = voltage across plates (V)
d = plate separation (m)

4. ENERGY STORED IN THE ELECTRIC FIELD

Work is done to move charge from one plate to the other against the electric field. This work is stored as electric potential energy.

Energy stored:

$$U = \frac{1}{2} C V^2$$

U = energy (joules)
C = capacitance (farads)
V = voltage across capacitor (volts)

WHY ENERGY IS STORED IN THE ELECTRIC FIELD

When the capacitor is charged, the source does work to separate charges and build up an electric field. The field exerts forces on the charges. The energy is stored in this field, not in the plates or dielectric themselves.

Energy density (energy per unit volume):

$$u = \frac{1}{2} \varepsilon E^2$$

ε = permittivity of the dielectric (F/m)
E = electric field (V/m)

Total energy = energy density × volume between plates

$$U = u \cdot (Ad) = \frac{1}{2} \varepsilon E^2 Ad = \frac{1}{2} C V^2$$

A = plate area (m^2)
d = plate separation (m)

ALTERNATE FORMS

In terms of charge Q:

$$U = \frac{Q^2}{2C}$$

Q = charge on each plate (C)
C = capacitance (F)

In terms of voltage V:

$$U = \frac{1}{2} C V^2$$

V = voltage across plates (V)
C = capacitance (F)

In terms of charge and voltage:

$$U = \frac{1}{2} Q V$$

Q = charge on each plate (C)
V = voltage across plates (V)

EXAMPLE

A 10 µF capacitor is charged to 12 V. How much energy is stored?

$$\begin{aligned} U &= \frac{1}{2} C V^2 \\ &= \frac{1}{2} (10 \times 10^{-6}) (12)^2 \\ &= 7.2 \times 10^{-4} \text{ J} \\ &= 0.72 \text{ mJ} \end{aligned}$$

0.72 millijoules of energy is stored in the electric field.

ENERGY VIEW

When the capacitor discharges, the electric field collapses and the stored energy is returned to the circuit.

KEY TAKEAWAYS

- ✓ A capacitor stores energy in the electric field between its plates.
- ✓ Charging the capacitor builds up equal and opposite charges ±Q.
- ✓ The energy stored increases with higher capacitance and higher voltage.
- ✓ Energy is released when the capacitor discharges.

Capacitance (for parallel-plate capacitor):

$$C = \varepsilon \frac{A}{d}$$

ε = permittivity of dielectric (F/m)
A = plate area (m^2)
d = plate separation (m)

COMMON APPLICATIONS

10.1.5 Electrostatic potential energy

Let us consider two electric charges q_1, q_2. The first is supposed to be at rest and fixed; the second is brought from infinity to a distance a from q_1 (the same reasoning was applied to the gravitational field in the section of Classical Mechanics!). Suppose that the two charges are of the same sign. As q_1, q_2 tend to repel each other, we have to provide a potential energy E_p to take q_2 (infinitely slowly) of q_1. The work $\mathrm{d}W$ done by the electrostatic force at any point is by definition as we know:

$$\mathrm{d}W = F \mathrm{d}x \tag{10.1.143}$$

The potential energy of the system is:

$$\mathrm{d}E_p = -\mathrm{d}W \tag{10.1.144}$$

as the force F is resistive (hence the origin of the sign "$-$").

Therefore:

$$\mathrm{d}E_p=-\mathrm{d}W=-F\mathrm{d}x=-\frac{q_1q_2}{4\pi\varepsilon}\frac{1}{x^2}\mathrm{d}x \tag{10.1.145}$$

We then get the potential energy at a point (x in the numerator is simplified with an x in the denominator) to a given sign convention:

$$\boxed{E_p=\frac{q_1q_2}{4\pi\varepsilon}\frac{1}{x}} \tag{10.1.146}$$

If we have $q_2=Zq_1$ where $Z\in\mathbb{N}$ and we denote $q_1=e$ then we fall back on a well known way to write the previous relation:

$$E_p=\frac{Ze^2}{4\pi\varepsilon}\frac{1}{x} \tag{10.1.147}$$

If the path is not linear we have obviously as in Classical Mechanics with the electric field and using the notations seen at the beginning of the section:

$$E_p=-W=-\int\limits_{\Gamma}q\vec{E}\circ\mathrm{d}\vec{s}=\int\limits_{\Gamma}q\vec{\nabla}\cdot U\circ\mathrm{d}\vec{s} \tag{10.1.148}$$

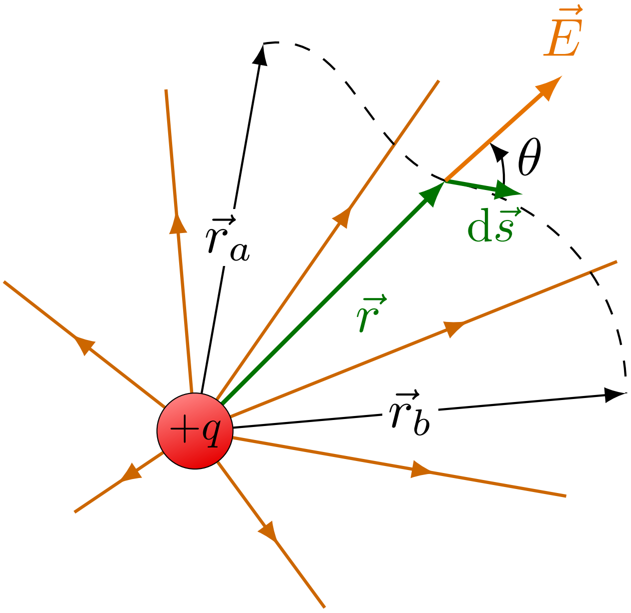

Figure 10.25: **Illustration of the work path in an electric field (author: Izaak Neutelings)**

Notice that:

$$E_p=\frac{q_1q_2}{4\pi\varepsilon}\frac{1}{x} \tag{10.1.149}$$

can also be written as:

$$E_p=q_1U_2=q_2U_1=\frac{1}{2}(q_1U_2+q_2U_1) \tag{10.1.150}$$

Caution! When we do physics, we have to be sure what potential energy we are talking about. This is a major problem! If you take for example the potential energy due the gravitational interaction, it can take any value depending on the reference point. If the reference is at sea level, a point below the sea level will have a negative potential energy, by cons if the reference is the center of the Earth, there will be only positive potential energies. That is why we are writing rather the potential energy in the form of height difference relative to a reference in mechanics. For the potential energy of the electron, we must know with what it interacts. If it is with a negative charge, the product of the electric charge values will be positive and therefore the potential energy of interaction will be positive, if it interacts with a positive charge, the product will be negative and the potential energy will be negative. In short, we must know what we are talking about. This is an example where words are important in physics too (same problems as the foundations of mathematics!).

In general, if the potential energy decreases when the distance increase, the force is repulsive if it increases when the distance increase, the force is attractive.

10.2. Magnetostatics

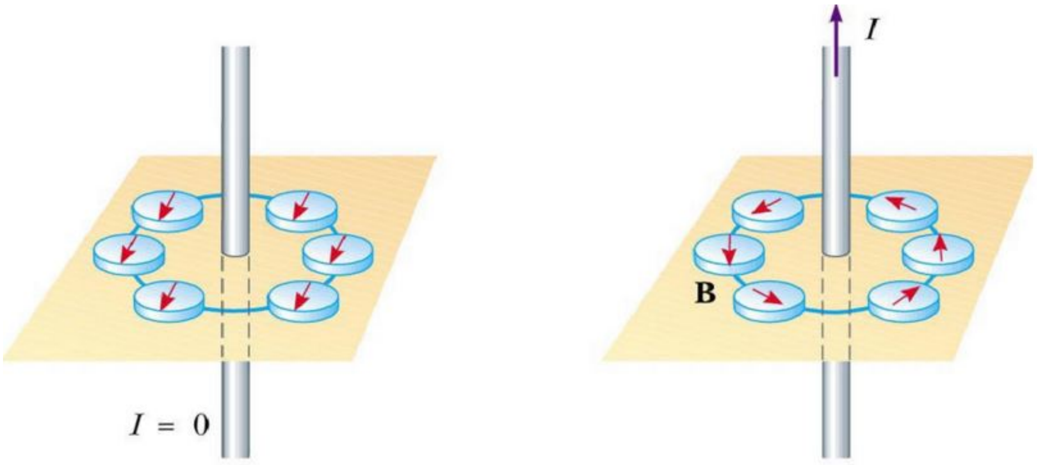
MAGNETS are known since ancient times (without that it was known at that the origin of their properties) under the name "magnetite": black stones found near the city of Magnesia (Turkey). This is from this stone that also comes the current name of the "magnetic field". The Chinese were the first to use the properties of the individual magnets more than 1,000 years before compasses. They consisted of a magnetite needle resting on straw floating on the water contained in a graduated container.

Magnetostatics is the study of magnetic fields in systems where the currents are steady (not changing with time). It is the magnetic analogue of electrostatics, where the charges are stationary. The magnetization need not be static; the equations of magnetostatics can be used to predict fast magnetic switching events that occur on time scales of nanoseconds or less. It is even a good approximation when the currents are not static - as long as the currents do not alternate rapidly.

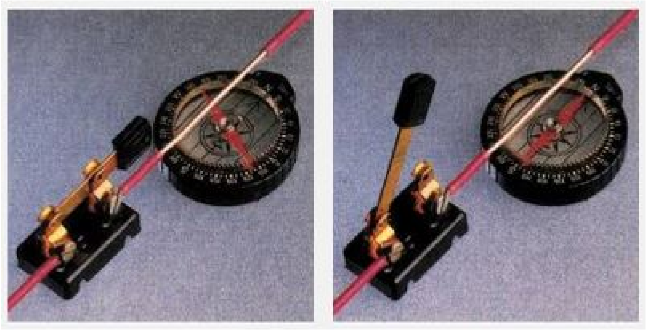
As for the electric field, a good/better understanding of the origin of this field can be done through modern theories such as wave quantum physics and quantum field theory. The beginner reader will have therefore to be patient, as for the study of the electric field, until to get in this textbook the knowledge to study these modern theories.

The quantitative study of the interactions between magnets and currents was made by the physicists Biot and Savart in 11820 only according to holocene calendar (nobody knew before that the compass was influenced by the current inside the core of the Earth). They measured the amplitude of the oscillations of a magnetic needle according to its distance to a straight current. They found that the force acting on a pole is directed perpendicular to the direction connecting the center to this conductor wire and it varies inversely with the distance. This is the first case that we will study.

The idea of the experiment was the following:



Or in real life with a much simple configuration:



Given a movement of electric charges (i.e.: a current I) generating in the space a vector field whose effects are measurable and whose properties differ from those of the electrostatic field. We deduce the existence of a new vector field we name (temporarily) "magnetic field" and which we denote by $\vec{B}$.

The physical units of the magnetic field will naturally been deduced from the time we will be able to connect this magnetic field to something known as a Force for example. This is what we will see further below during our study of the "Laplace's force law".

The simplest case of study consisting of an indefinite straight conductor wire (example that we can also assimilate to a simple move of charges without having necessarily a wire to carry them) carrying a current I (see the section Electrokinetics for the concept of "current") shows that the magnetic field lines are circles having for axis the conductor wire itself:

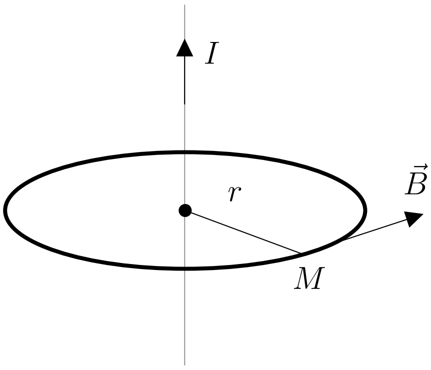


Figure 10.26: **Magnetic field around a straight infinite wire**

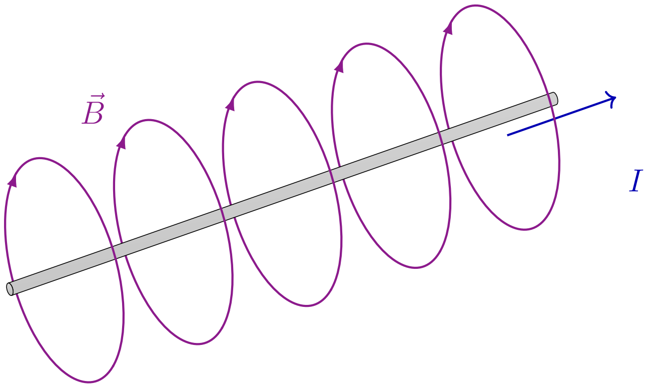
Caution!! As we will prove it in the section of Special Relativity (see page 5694), the magnetic field and electric fields from moving charges (do not confuse it with the magnetic field of spin!) are not different things they are the two sides of the same coin. A magnetic field produced by moving charges is just an electric field viewed from a different moving frame of reference!!! More explicitly the motion of a charged particle (which has dimensions and therefore finite charge density) causes a Lorentz contraction along the line of its motion. This causes the particle to see all stationary charges as denser in that direction and, therefore, it experiences an increased electrostatic force from them that is interpreted as a new kind of field: the magnetic field!

Or in perspective (if it may help the reader to understand better the concept):



The direction of $\vec{B}$ is usually defined by the intermittance of "Ampère's observer", that is to say, an observer that would be positioned along the wire, so that the current goes to its feet towards its head and who would look at the point M where we evaluate the magnetic field. The field $\vec{B}$ is directed from the right to the left of this observer. This is represented many times by the following figure:

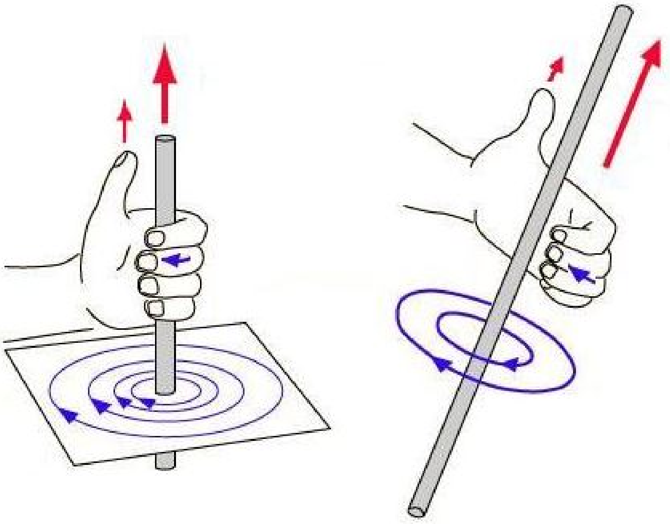


Figure 10.27: Ampère observer hand rule

It is said that is was experimentally established by Biot and Savart in 11820 (holocene calendar) that the norm of the magnetic field $\vec{B}$ at the distance r of the wire is proportional to the current I running through it and inversely proportional to r such that:

$$B = kIr^{-1} \tag{10.2.1}$$

This relation is traditionally considered as the pillar of the study of the magnetic field.

The proportionality coefficient k depends as always to selected unit system (as for other study fields). For the set of all its consequences, it is advantageous to write the above expression in a form that makes appear the perimeter of the circle of radius r. So we put:

$$k = \frac{\mu_0}{2\pi} \tag{10.2.2}$$

Remark

Don't forget that as 2π appears frequently in many theorems of physics and mathematics (more than π alone), this value is frequently denoted by the letter τ.

Thus we obtain the value of the magnetic field at a distance r from a straight conductor wire through which a constant current I pass through:

$$\boxed{B = \frac{\mu_0 I}{2\pi r}} \tag{10.2.3}$$

where μ_0 is a new constant which we name "magnetic permeability of vacuum" (again as for the electrical permittivity, there is a "relative magnetic permeability") and whose value is given as usual in this textbook with the other physical constants in the section Principles of Mechanics chapter.

The units of this constant, even if given in the section Principias of the Mechanics chapter, will be deducted automatically as soon as we have managed to link the magnetic field with the concept already known of "Force" (see below). This is what we will see when we will study the "Laplace's force law".

10.2.1 Ampère's theorem

In classical electromagnetism, the "Ampère's theorem" or "Ampère's circuital law" or simply "Ampère's law" relates the integrated magnetic field around a closed loop to the electric current passing through the loop.

It is interesting to calculate the "circulation of the magnetic field" $\vec{B}$ in vacuum (or not) along a contour Λ that turns once in the positive direction (anti-clockwise) around the wire oriented in the direction of the current (Ampère observer):

$$C_B = \oint\limits_{\Gamma} \vec{B} \circ \mathrm{d}\vec{l} = \oint\limits_{\Gamma} B \cdot \mathrm{d}l = \int\limits_0^{2\pi} B \cdot r \cdot \mathrm{d}\theta = \frac{\mu_0 \cdot I}{2\pi} \int\limits_0^{2\pi} \mathrm{d}\theta = \mu_0 \cdot I \tag{10.2.4}$$

Remark

The field is collinear along the path as we have seen previously hence the fact that the dot product can be written as a simple product of norms.

We obtain then by definition the "Ampère's law" (or erroneously named "Ampère's theorem" because this result is not provable ... at least as far as we know...):

$$\boxed{C_B=\oint\limits_{\Gamma}\vec{B}\circ \mathrm{d}\vec{l}=\mu_0 I} \tag{10.2.5}$$

where the current I in a high symmetry system can be assimilated to a simple algebraic sum of currents snared by the path such that we have:

$$C_B=\oint\limits_{\Gamma}\vec{B}\circ \mathrm{d}\vec{l}=\mu_0\sum_k I_k \tag{10.2.6}$$

Warning!!! This is not because the circulation of the magnetic field is zero in a region of space that the magnetic field is zero at any point!

Remarks

R1. The Ampère's law will gives us the possibility to determine the fourth Maxwell equation that we will prove in the section of Electrodynamics.

R2. The prior-previous relation is sometimes wrongly named "Ampère theorem" when in fact this result is not provable as already mentioned. Some physicists, however, use the fourth Maxwell equation to prove the prior-previous relation but then this is the snake biting its tail...

The expression that we obtained can be simplified even more if we introduce a new physical being named "magnetic field intensity" or more commonly "magnetic excitation" and which is denoted by the letter $\vec{H}$ (which is intrinsically independent of the propagation medium!).

If we consider that we are always in the vacuum where there is no magnetic dipole then we define it in the vacuum by:

$$\vec{B}=\mu_0\vec{H} \tag{10.2.7}$$

Therefore, we are often taken to speak about "magnetic induction" for $\vec{B}$ and "magnetic field" for $\vec{H}$. But both are happily confused following the authors/professors/teachers and especially depending on the contexts (as will be the case also in this textbook). When we deal with magnets that have intrinsic magnetization by the properties of the material that are made from, we denote distinctly the external magnetic field by:

$$\boxed{\vec{B}=\mu_0(\vec{H}+\vec{M})} \tag{10.2.8}$$

which is a more general form of the previous relation. It is therefore usual to define the "magnetic susceptibility" as being the dimensionless ratio:

$$\chi_m=\frac{M}{H} \tag{10.2.9}$$

Thus, the magnetic susceptibility indicates the amplitude with which a material responds magnetically to the presence of a magnetic excitation. We then get by this definition, the relation between relative magnetic permeability and magnetic susceptibility:

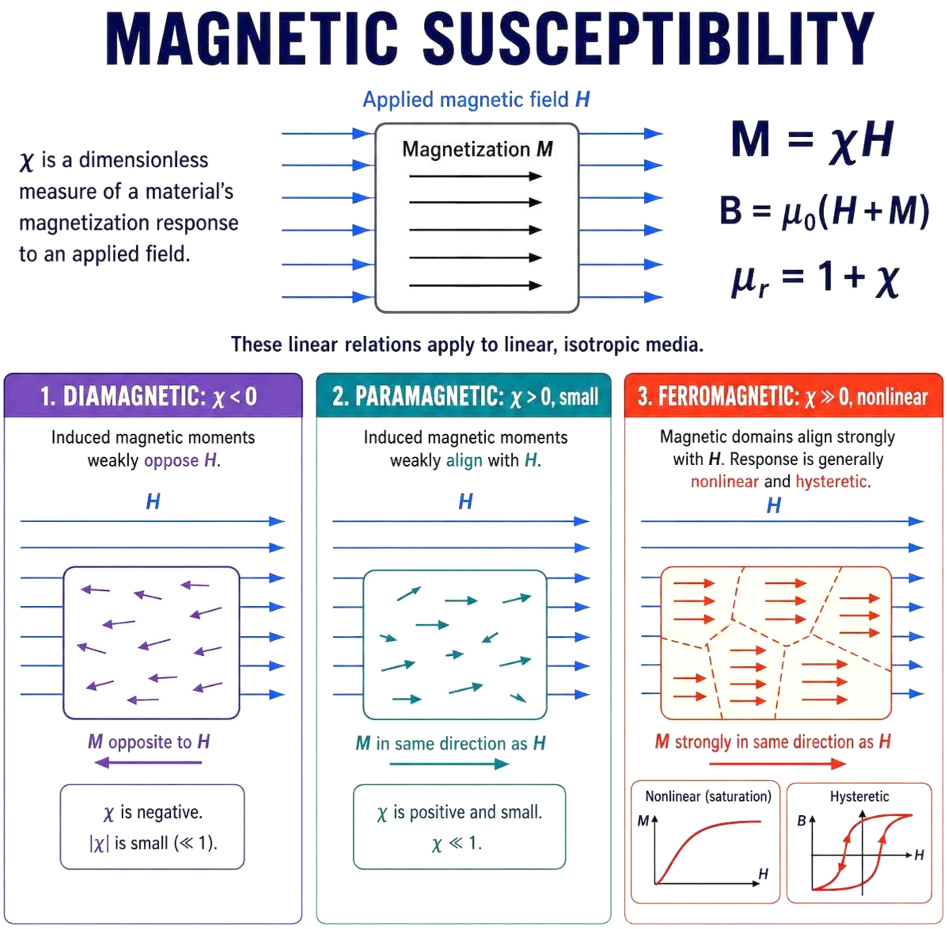
$$\vec{B}=\mu_0(\vec{H}+\vec{M})=\mu_0(\vec{H}+\chi_m)\vec{H}=\mu_0\mu_r\vec{H}=\mu\vec{H} \tag{10.2.10}$$

Therefore:

$$\boxed{\mu_r=\frac{\mu}{\mu_0}=1+\chi_m} \tag{10.2.11}$$

where μ is named the "absolute magnetic permeability".

It is customary to name materials that have a positive magnetic susceptibility "paramagnetic materials" (contributing to increase the magnetic field) and those with a negative magnetic susceptibility "diamagnetic materials" (tend to oppose to the magnetic field). We will see later the Langevin theoretical models to explain quantitatively with a relatively good approximation the two phenomena (in both cases the magnetic susceptibility has a value which is very low).



MAGNETIC SUSCEPTIBILITY
Applied magnetic field H
χ is a dimensionless measure of a material's magnetization response to an applied field.
Magnetization M
M = χH
B = μ0(H+M)
μr = 1 + χ
These linear relations apply to linear, isotropic media.
1. DIAMAGNETIC: χ < 0
Induced magnetic moments weakly oppose H.
H
M opposite to H
χ is negative.
|χ| is small (≪ 1).
2. PARAMAGNETIC: χ > 0, small
Induced magnetic moments weakly align with H.
H
M in same direction as H
χ is positive and small.
χ ≪ 1.
3. FERROMAGNETIC: χ ≫ 0, nonlinear
Magnetic domains align strongly with H. Response is generally nonlinear and hysteretic.
H
M strongly in same direction as H
Nonlinear (saturation)
M
H
Hysteretic
B
H

So finally we can also write the Ampère's Law as following:

$$\oint_{\Gamma}\vec{H}\circ\mathrm{d}\vec{l}=I \tag{10.2.12}$$

The interest of the Ampère's law and of the concept of circulation of the magnetic field may appears like this more evident.

This latter relation obviously is obviously very useful in theoretical physics because it will allow us to determine other important powerful results. Otherwise, in practice, the physicist or electrician/electrical engineer will often be faced with having to use electromagnets for small and medium experiences which he may wish to recalibrate the nominal values, or even solenoids.

10.2.1.1 Infinitely long solenoid

Also a particularly important application in electronics and electrical engineering is the calculation of the induction field in a coil of wire through which pass a current that we will consider as constant in a first time. This is nothing more than an induction coil more technically named an "inductance". Let's see what it is:

A solenoid is a coil of wire formed by a conductor wire wound helically through which pass a current of intensity I. In what follows, we assume that the induction field $\vec{B}$ of a solenoid is zero between the coils and parallel to the axis of the solenoid.

Let us consider the following figure and let us look in approximation only to the inside part of the solenoid admitting that the external field is zero by the infinite length of it and that the joins of the coils are perfect (not letting dissipate any magnetic field)...:

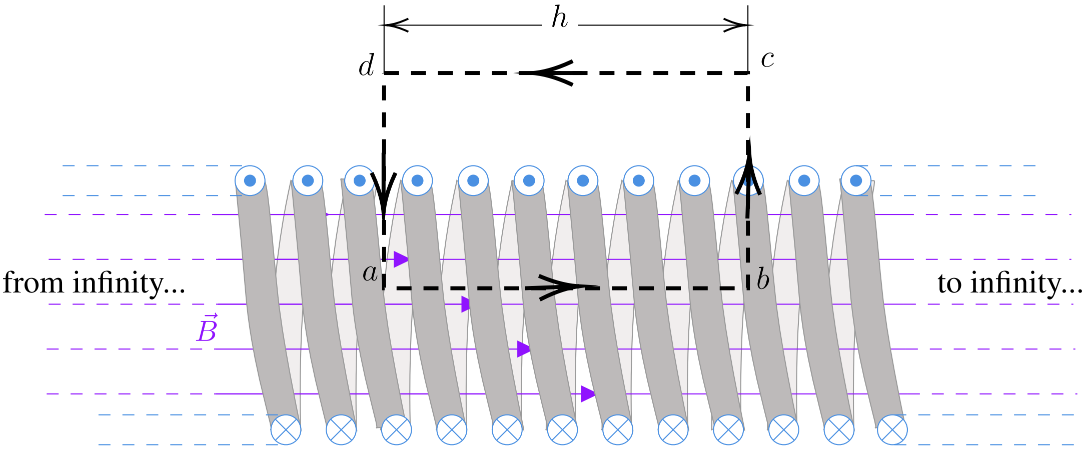


Figure 10.28: Infinite solenoid (coil of wire)

Let us apply the Ampère law to a rectangular path $abcd$. Therefore:

$$\oint \vec{B} \circ \mathrm{d}\vec{l} = \int_a^b \vec{B} \circ \mathrm{d}\vec{l} \qquad (10.2.13)$$

The first integral of the right member gives $B \cdot h$ where B is the norm of $\vec{B}$ inside the solenoid and h the length of the segment $\overline{ab}$. We can notice that the segment $\overline{ab}$, even if it is parallel to the axis of the solenoid, don't need not coincide with it.

The second and fourth integral is equal zero because for these two segments $\vec{B}$ and $\mathrm{d}\vec{l}$ are everywhere perpendicular: as $\vec{B}\circ\mathrm{d}\vec{l}$ is zero everywhere, the two integrals are equal to zero. The third integral is also equal to zero since the segment is calculated outside the solenoid where we assumed that the magnetic field is equal to zero as we consider the solenoid to be perfect.

Thus, the integral $\oint\vec{B}\circ\mathrm{d}\vec{l}$ for the entire rectangular path is equal to $B\cdot h$ such that:

$$\oint\vec{B}\circ\mathrm{d}\vec{l}=B\cdot h=\mu_0 I \tag{10.2.14}$$

but the current I is the sum of the currents I_0 passing through the N turns contained in the path of integration. But in electronics, we used to work with the value n (we choose the lowercase letter by analogy to Thermodynamics where lowercase letters represent densities) which is the number of turns per unit length:

$$n=\frac{N}{h} \tag{10.2.15}$$

Therefore we have:

$$B\cdot h=\mu_0\cdot I=\mu_0\cdot I_0\cdot N\Rightarrow B=\mu_0 I_0 n \tag{10.2.16}$$

That is:

$$\boxed{B=\mu_0\frac{I_0N}{h}=\mu_0 I_0 n} \tag{10.2.17}$$

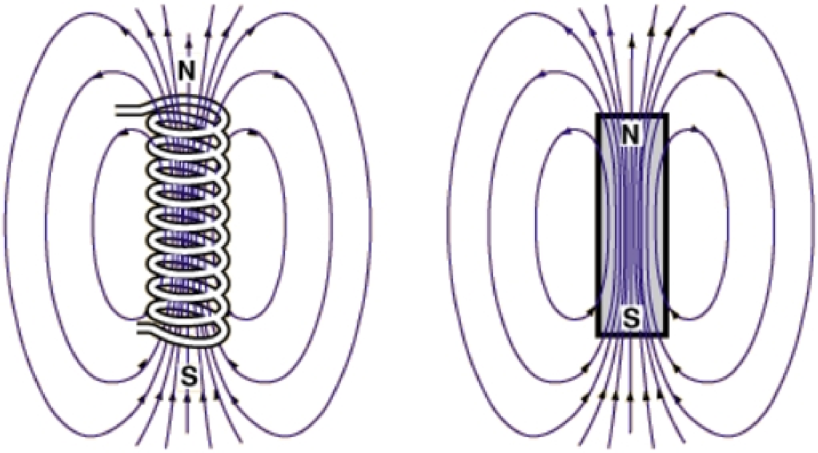

Figure 10.29: **Linear solenoid analogy with (dipole) magnet (source: ?)**

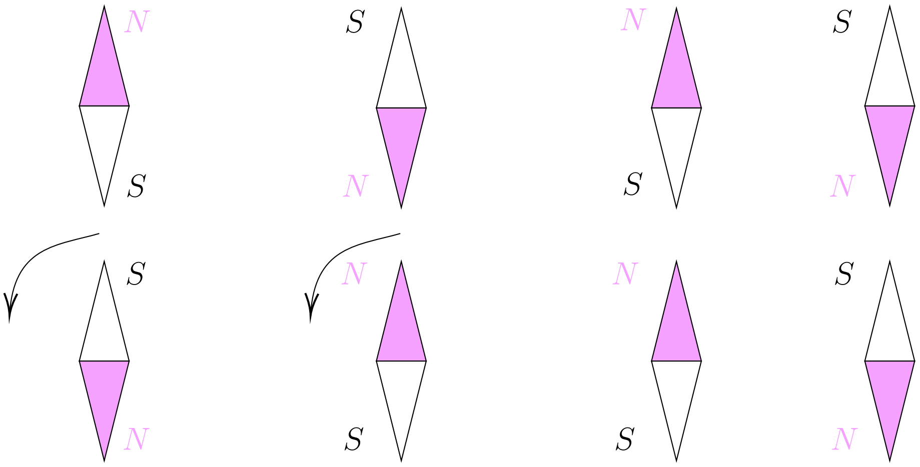
Even if this relation has been established for an ideal infinite solenoid, it gives a pretty good magnitude (but not exact!) of magnetic induction field for interior points near the center of a real solenoid! This relation also shows that the magnetic field is independent in approximation of the solenoid diameter and that this latter is uniform across the section thereof!!! In laboratories, a solenoid is a convenient device for producing a uniform field induction in the same way that the plane capacitor is used to produce a uniform electric field.

If we approach two solenoids (or magnetic needle) free to orient themselves we notice that :

- Two poles of the same nature repel each other
- Two poles of different nature attract

This property is used to determine the nature of the poles of any magnet: it suffices to approach a compass towards one of the ends of the magnet and observe which pole is attracted. The unknown magnet pole will then be of a different nature.

Here is an illustration of the magnetic actions between two magnets:



a) Unstable positions: the poles of the same nature repel each other

b) Stable positions: the poles of different nature attracts

As magnetic field can't be perfectly isolated because any lab on Earth and in space is inside the Earth's natural magnetic field (same as for the gravitational field), the world isolation record known so far is held by the shielding room at the Paul Scherrer Institute in Switzerland (see photo below) with a magnetic field measured as less than 150 picotesla (for comparison the Earth's magnetic field is 30 to 60 microtesla, several hundred thousand times stronger):

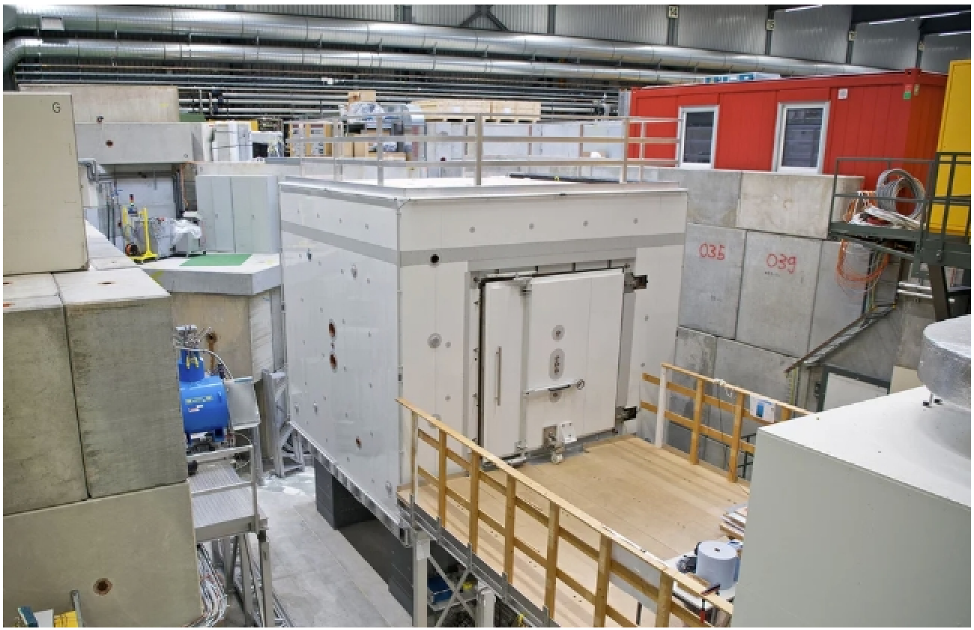


Figure 10.30: **The shielding room at Paul Scherrer Institute**

10.2.1.2 Toroidal coils

The toroidal coil is another important example of the application of Ampère's law. Indeed, we especially find this configuration in low power electronics (e.g. computers) where the inductors are mostly toroidal or in the energy production with the famous Tokomak that are (very ...) schematically reduced to toroidal coils.

Figure 10.31: **Toroidal coil**

For symmetry reasons, it is clear that the magnetic induction lines form concentric circles inside the coil. Let us apply Ampère's law to the radius r of integration of the circular path:

$$\oint \vec{B} \circ \mathrm{d}\vec{l} = \mu_0 I \tag{10.2.18}$$

That is to day:

$$B 2\pi r = \mu_0 I = \mu_0 I_0 N \tag{10.2.19}$$

If follows then:

$$\boxed{B = \frac{\mu_0}{2\pi} \frac{I_0 N}{r}} \tag{10.2.20}$$

Thus, unlike B inside a solenoid, B is not constant within the toroidal coil.

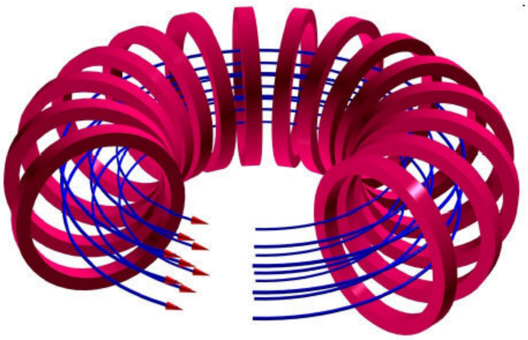

Figure 10.32: **Toroidal field**

10.2.1.3 Electromagnet

Let us determine for example (important and interesting one!) the magnetic field in the air gap of length L_a and section S_a of an electromagnet of length L_{Fe} and section S_{Fe} as shown below:

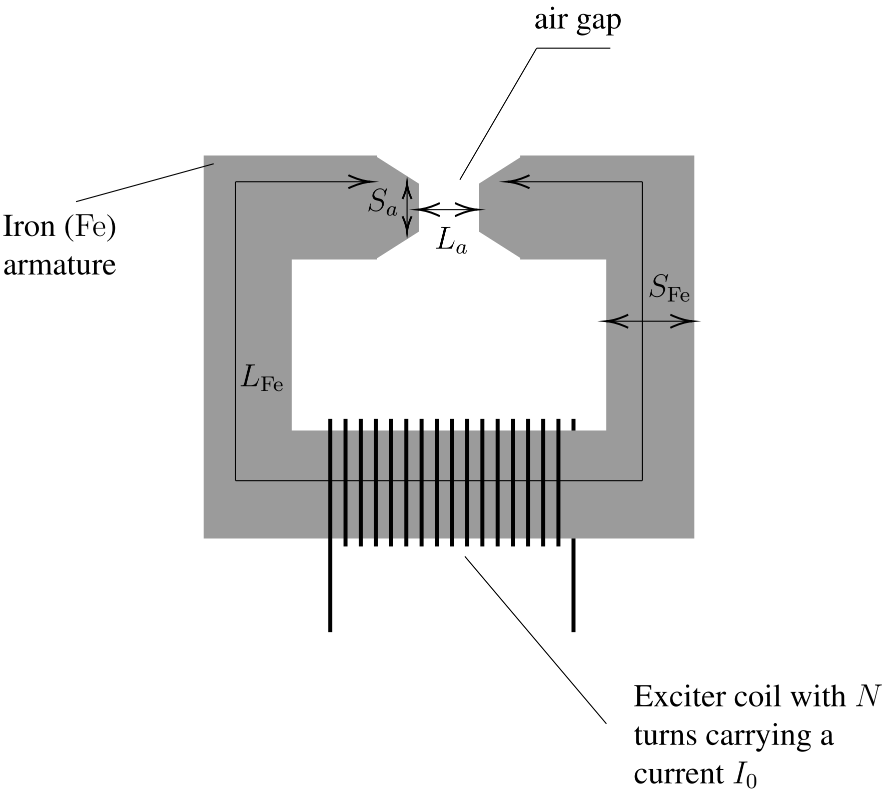

Figure 10.33: Schematic rectangular electromagnet

The Ampère's law gives us in vacuum:

$$\oint_{\sigma} \vec{B} \circ \mathrm{d}\vec{l} = \mu_0 \sum_k I_k \tag{10.2.21}$$

in the case of the electromagnet, we can write that the circulation of the field is the sum of the circulation of the air gap field and the magnet field itself:

$$\oint_{\Sigma} \vec{H} \circ \mathrm{d}\vec{l} = H_{\text{Fe}} L_{\text{Fe}} + H_{\text{airgap}} L_{\text{airgap}} = \sum_k I_k = N I_0 \tag{10.2.22}$$

where N corresponds to the number of current loops surrounding the magnet and which allows the production of the magnetic field.

Let us recall that we have by definition:

$$H_{\text{Fe}} = \frac{B_{\text{Fe}}}{\mu_{\text{Fe}}} \quad \text{and} \quad H_{\text{airgap}} = \frac{B_{\text{airgap}}}{\mu_{\text{airgap}}} \tag{10.2.23}$$

Therefore:

$$\oint_{\Sigma} \vec{H} \circ \mathrm{d}\vec{l} = H_{\text{Fe}} L_{\text{Fe}} + H_{\text{airgap}} L_{\text{airgap}} = \frac{B_{\text{Fe}}}{\mu_{\text{Fe}}} L_{\text{Fe}} + \frac{B_{\text{airgap}}}{\mu_{\text{airgap}}} = N I_0 \tag{10.2.24}$$

If the airgap is not to big $L_{\text{Fe}} >> L_{\text{airgap}}$ we can write:

$$B_{\text{airgap}} \cong B_{\text{Fe}} \tag{10.2.25}$$

Therefore:

$$NI_0 = B_{\text{airgap}}\left(\frac{L_{\text{Fe}}}{\mu_{\text{Fe}}}+\frac{L_{\text{airgap}}}{\mu_{\text{airgap}}}\right) \Leftrightarrow B_{\text{airgap}} = \frac{NI_0}{\dfrac{L_{\text{Fe}}}{\mu_{\text{Fe}}}+\dfrac{L_{\text{airgap}}}{\mu_{\text{airgap}}}} = \frac{NI_0}{\dfrac{L_{\text{Fe}}}{\mu_{\text{Fe}}\mu_0}+\dfrac{L_{\text{airgap}}}{\mu_{\text{airgap}}\mu_0}} \tag{10.2.26}$$

Finally:

$$\boxed{B_{\text{airgap}} \cong \frac{\mu_0 NI_0}{\dfrac{L_{\text{Fe}}}{\mu_{\text{Fe}}}+L_{\text{airgap}}}} \tag{10.2.27}$$

The relation is the same for an electromagnet having two coils! The reader will have perhaps notice on the way that this relation can also be used experimentally if we seek to determine the value of the relative magnetic permeability of the iron when all other parameters are known.

10.2.1.3.1 Strength of a magnet or electromagnet

If we have know the norm of the magnetic field B produced by a magnet at its surface, we can calculate with a certain approximation the force required to detach it from an iron surface.

For this, we will denote by F the necessary force to take off the magnet from a distance d of an iron surface. We will assume the distance d to be sufficiently small distance so that we can accept that the in the entire volume between the magnet and the iron, the magnetic field is constant.

Thus, the work done by the force F is (see section Classical Mechanics page 3293):

$$W = Fd \tag{10.2.28}$$

This work has been turned into magnetic field energy in the volume defined between the magnet and iron. The volumetric energy density due to the magnetic field of air being (see section Electrodynamics page 4156):

$$u_B = \frac{1}{2\mu}B^2 \tag{10.2.29}$$

The volume of the space generated between the magnet and the iron being equal to $V = Sd$ where S is the surface of the magnet that was bonded to iron. We then have the following dimensional equivalence:

$$Fd = \left(\frac{1}{2\mu_0}B^2\right)Sd \tag{10.2.30}$$

Hence we deduce the contact force for small values of d:

$$\boxed{F = \left(\frac{1}{2\mu_0}B^2\right)S} \tag{10.2.31}$$

where B is the limit value of the magnetic field which causes our material to stick to the magnet (so that by raising the magnet, the associated material follows).

If we look at a lifting electromagnet of radius 0.75 [m] capable of lifting 200 [kg]:

Figure 10.34: **Lifting electromagnet**

Then we have:

$$B=\sqrt{\frac{2\mu_0 mg}{S}}=\sqrt{\frac{2\mu_0 mg}{\pi R^2}}\cong 0.05\;[\text{T}] \tag{10.2.32}$$

We can also use roughly the same calculation to determine the magnetic field of the electromagnet of the famous worldwide following playful toy known by people passionate in physics:

Figure 10.35: **Playful lifting electromagnet**

10.2.2 Maxwell-Ampère Relation

Given $\vec{J}$ the current density at any point of the space in the case of a three-dimensional distribution and let S be a closed surface which is based on any contour Γ. The current I that pass through Γ is of course given by:

$$I=\oint\limits_S \vec{J}\circ\mathrm{d}\vec{S} \tag{10.2.33}$$

According to Ampère's law, the flow of the magnetic field along Γ is equal to this integral. It may therefore take here, given the selected contour Γ, an infinite continuous variable values. On the other hand, the Stokes' theorem (see section Vector Calculus page 1889) gives us that:

$$\int\limits_\Gamma \vec{B}\circ\mathrm{d}\vec{l}=\oint\limits_S \vec{\nabla}\times\vec{B}\circ\mathrm{d}\vec{S} \tag{10.2.34}$$

Therefore:

$$\int\limits_\Gamma \vec{B}\circ\mathrm{d}\vec{l}=\mu_0 I=\mu_0\oint\limits_S \vec{J}\circ\mathrm{d}\vec{S}=\oint\limits_S \vec{\nabla}\times\vec{B}\circ\mathrm{d}\vec{S} \tag{10.2.35}$$

and finally we conclude that:

$$\boxed{\vec{\nabla}\times\vec{B}=\mu_0\vec{J}} \tag{10.2.36}$$

We can make a bold comparison of this result with the relation below (proven in the section Electrodynamics), by extension of the static and dynamic electric charge:

$$\vec{\nabla}\circ\vec{E}=\frac{\rho}{\varepsilon} \tag{10.2.37}$$

which is nothing else than the first Maxwell equation (see section Electrodynamics page 4095). Therefore, as we have seen in the section Electrostatics, we have:

$$\vec{E}=\frac{1}{4\pi\varepsilon}\iiint\limits_V \frac{\rho(\vec{r})}{r^2}\mathrm{d}V \tag{10.2.38}$$

By analogy, the idea is to put (this assumption is verified a little further below in the text by the remarkable results obtained):

$$\vec{B}=\frac{\mu_0}{4\pi}\oint_V \frac{J(\vec{r})}{r^2}\mathrm{d}V \tag{10.2.39}$$

relation that we can write in a more elegant way by assuming the current not dependent on the observer's position in space and collinear with perpendicular vector perpendicular of the crossing surface:

$$\vec{B}=\frac{\mu_0}{4\pi}\oint_V \frac{J(\vec{r})}{r^2}\mathrm{d}V=\frac{\mu_0}{4\pi}\oint_V \frac{\dfrac{I(\vec{r})}{S}}{r^2}\mathrm{d}V=\frac{\mu_0}{4\pi}\oint_\Gamma \frac{I(\vec{r})}{r^2}\mathrm{d}l=\frac{\mu_0}{4\pi}I\oint_\Gamma \frac{\mathrm{d}\vec{l}}{r^2} \tag{10.2.40}$$
